ABSTRACT

Large-scale sharing of dialogue data is key to advancing the science of teaching and learning, yet rigorous de-identification remains a major barrier. In mathematics tutoring transcripts, numeric expressions frequently resemble structured identifiers (e.g., dates or IDs), leading generic Personally Identifiable Information (PII) detection systems to over-redact core instructional content and reduce data utility. This work asks how to detect PII while preserving educational utility, focusing on this "numeric ambiguity" problem. We introduce MathEd-PII, the first benchmark dataset for PII detection in math tutoring dialogues, built with human-in-the-loop LLM annotation. Using density-based segmentation, we show that false PII redactions cluster in math-dense regions, confirming numeric ambiguity as a key failure mode. We then compare four detection strategies: a Presidio baseline and three LLM-based approaches with basic, math-aware, and segment-aware prompting. Domain-aware prompting, including both math-aware (F1: 0.802) and segment-aware versions (F1: 0.821), substantially outperforms the baseline (F1: 0.379) while reducing numeric false positives, demonstrating that de-identification must incorporate domain context to preserve analytic utility. This work provides a new benchmark and evidence that utility-preserving de-identification for tutoring data requires domain-aware modeling.

1. INTRODUCTION

The Educational Data Mining (EDM) community has long relied on large-scale open source data sets from digital learning platforms [14, 18]. Many of these data sources can be easily de-identified because they are composed of action logs that, for the most part, do not typically contain personally identifiable information (PII). As more and more educational technologies provide dialogue-based tutoring at scale, either with humans or with artificial intelligence (AI) chatbots [3, 8, 22, 26], access to large corpora of tutoring conversations has become essential. However, sharing such data requires rigorous de-identification to remove direct identifiers (e.g., names and email addresses) and quasi-identifiers (e.g., gender, ages, locations, and school names) that could enable re-identification of specific individuals.

Recent work has begun to develop tools and workflows for de-identifying educational text [9, 10, 24, 25, 31, 32]. Yet specialized domains like mathematics tutoring introduce a distinct and underexplored challenge. In math dialogue, numbers are the primary medium of exchange. A teacher might ask, "Are 4/12 and 2/6 the same?" (fractions), or a student might calculate "500 - 70 - 2000" (subtraction). Standard PII detectors frequently misidentify these mathematical expressions as `DATE` or `US_SSN` due to *numeric ambiguity*, the overlap between the surface forms of mathematical content and sensitive identifiers. Over-identifying these math-related spans results in low precision, stripping the data of its core educational content and rendering it useless for downstream tasks.

A second barrier is the lack of domain-specific benchmarks. To date, no publicly available dataset exists for evaluating PII detection in math tutoring contexts, limiting the ability to rigorously study and improve de-identification methods for this increasingly important data modality.

To overcome these barriers, this work addresses the following research question (RQ): How can we accurately detect PII in math tutoring transcripts while preserving the educational utility of the data? We operationalize this question

through three sub-questions that structure the remainder of the paper:
RQ1 (Failure analysis): To what extent does numeric ambiguity in mathematical discourse lead to false positive PII detection?
RQ2 (Dataset construction): How can a reliable benchmark for evaluating PII detection be created when original unredacted data cannot be shared?
RQ3 (Method evaluation): Do math-aware prompting strategies improve utility-preserving PII detection compared to domain-agnostic baselines?

To answer these questions, we begin with a large corpus of math tutoring transcripts that had already been redacted for PII by the data provider. The original unredacted data are unavailable because the data provider's internal data safety regulation requires responsible removal of PII before any data sharing can happen. Therefore, we developed a human-in-the-loop large language model (LLM) workflow to audit and repair PII redactions done by the data provider before they shared the data with us and to generate privacy-preserving surrogates. This process yields **MathEd-PII**[1], a benchmark dataset of 1,000 tutoring sessions (115,620 messages; 769,628 tokens) for evaluating PII detection in math tutoring dialogue.

We find that numeric expressions are a major source of false PII detections in math tutoring dialogue. Using a segmentation analysis to examine how detection errors differ between math-dense and conversational regions of transcripts, we observe 55.5% of false redactions to occur in math-dense segments that cover only 36.6% of the corpus, whereas true PII appears substantially less often in these regions (22.2%). We evaluate four PII detection strategies: (i) a Presidio-based baseline, (ii) LLMs with basic prompting, (iii) LLMs with math-aware prompting, and (iv) LLMs with segment-aware prompting. Math-aware prompting substantially improves performance over the baseline (F1: 0.821 vs. 0.379), primarily by reducing numeric false positives. These findings demonstrate that de-identification for tutoring dialogue cannot be treated as a domain-agnostic preprocessing step; preserving analytic utility requires incorporating mathematical discourse context.

This paper makes three contributions aligned with the RQs above. We identify numeric ambiguity as a central failure mode in de-identifying math tutoring dialogue (RQ1). We then introduce MathEd-PII, the first benchmark dataset for PII detection in math tutoring transcripts (RQ2). Finally, we show that math-aware prompting substantially improves utility-preserving de-identification (RQ3).

2. RELATED WORK

2.1 Policy Context

De-identification is a prerequisite for sharing educational interaction data at scale, but what counts as "sufficient" de-identification depends on the legal regime and the assumed adversary model. In the United States, the Children's Online Privacy Protection Act (COPPA) and the Family Educational Rights and Privacy Act (FERPA) govern education records and only permits disclosure of de-identified information when there is no reasonable basis to believe the remaining information can be used to identify an individual [4, 29].

In parallel, the Health Insurance Portability and Accountability Act (HIPAA) provides two common pathways for de-identification of health information–*Safe Harbor* (removal of 18 enumerated identifiers, e.g., names, geographic subdivisions smaller than a state, dates directly related to an individual, and unique identification numbers) and *Expert Determination* (a documented, risk-based assessment) [30]. Although specific to health data, the 18 identifiers are widely used as a practical reference beyond that domain because they offer "the promise of a straightforward application of rules, a repeatable process, and a known result: a dataset that is legally de-identified" [6, p. 24]. Despite this apparent clarity, the National Institute of Standards and Technology (NIST) emphasizes that de-identification is inherently dynamic, framing it along an "identifiability spectrum" and cataloging transformation families such as suppression, generalization, perturbation, masking, and synthesis. Stronger privacy protections, it notes, typically come at the expense of analytic fidelity [6, 7].

2.2 PII Detection in Unstructured Text

Most practical pipelines for unstructured text de-identification begin with *entity detection* (identifying spans that correspond to PII) and then apply an *anonymization action* (e.g., redaction, masking, or surrogate replacement). Historically, detection approaches fall into three broad categories–rule-based, model-based, and LLM-based methods.

Rule-based PII detection systems rely on hand-engineered patterns and resources, including regular expressions for structured identifiers (e.g., emails, phone numbers, and dates), curated lexicons for names and locations, and deterministic context heuristics [21]. These methods can be highly precise for well-formed identifiers but brittle under conversational noise (misspellings, fragments, idiosyncratic formatting), and they require continual maintenance as domains shift [19].

A complementary line of work frames PII detection as a named entity recognition (NER) task, in which statistical or neural models predict entity spans over tokens or characters based on contextual cues. Contemporary NLP toolkits, most notably spaCy, provide pretrained and fine-tunable NER models that are commonly used as baseline PII detectors or adapted to domain-specific corpora [12]. In practice, many production systems combine *rule-based* and *model-based* paradigms to exploit their complementary strengths. Microsoft Presidio exemplifies this hybrid design by integrating rule-based recognizers for high-precision patterns with neural-network-based entity detectors within a unified anonymization framework [16].

More recently, LLMs have been applied to de-identification both via prompting and fine-tuning [24, 25, 31]. In prompting-based setups, the model is typically instructed (often with a schema) to tag or extract PII spans and entity types from raw text–either by returning structured outputs (e.g., JSON with character offsets and labels) or by

[1]https://huggingface.co/datasets/NationalTutoringObservatory/MathEd-PII

emitting an annotated/redacted version of the transcript—whereas fine-tuning-based setups train the model on labeled examples to produce consistent token-level tags or span predictions under a fixed output format [24].

2.3 Augmented and Synthetic data for PII Detection and Evaluation

A practical challenge in PII detection research is the scarcity of richly annotated, shareable corpora, as releasing PII labels alongside text can increase re-identification risk. To address this, two complementary strategies are increasingly common: data augmentation and synthetic data generation.

Data augmentation for PII detection starts from de-identified or manually redacted text and inserts synthetic PII spans, often through surrogate replacement schemes such as "hiding in plain sight," which preserve discourse coherence while reducing disclosure risk [2, 27]. In parallel, fully synthetic datasets have been constructed using template- or rule-driven generators and, more recently, LLMs conditioned on schema constraints (e.g., entity types, formats, and conversational style) [17, 23, 28]. These approaches offer controllability and improved coverage of rare entity types, but their effectiveness depends on the realism of the generated text: synthetic data that fails to capture domain-specific language, error patterns, or contextual ambiguity may yield overly optimistic performance estimates and limited transfer to real-world settings [23, 28].

2.4 De-Identification of Educational Data

Early work on de-identification in educational text focused on providing practical tooling and datasets to support privacy-preserving analysis of student writing and interaction data. Holmes et al. [9, 10] introduced PIILO, an open-source system for labeling and obfuscating PII in educational corpora, and examined de-identification challenges in student-authored texts across digitally mediated learning environments. Building on this foundation, Singhal et al. [25] conducted one of the first systematic evaluations of LLMs for educational data de-identification, using online course discussion forums as a testbed and demonstrating that LLMs substantially improve recall but often over-redact, motivating the need for utility-aware evaluation. Subsequent work by Zambrano et al. [31] expanded this analysis with larger-scale experiments and error analyses, further documenting precision–utility trade-offs in LLM-based anonymization of student forum posts. More recently, Shen et al. [24] proposed enhanced LLM-based pipelines that combine prompting and verification strategies to improve robustness across educational datasets, while Zent et al. [32] introduced an anonymization framework tailored to question-anchored tutoring dialogues, emphasizing deployability and domain adaptation. Together, this line of work reflects a rapid shift from rule-based and toolkit-oriented approaches toward LLM-centric methods, alongside growing recognition that educational domains pose distinct challenges for balancing privacy protection and analytic utility as it is conversational and tightly interleaves task content with incidental personal references.

Math tutoring transcripts present an additional challenge: beyond conversational noise, they contain dense, non-sensitive numerals and operators whose surface forms overlap with common PII categories such as `AGE`, `DATE`, and `ID`. Over-redacting this math-related content would severely reduce the downstream educational and research-related utility of the dataset. However, numerical false positives in PII detection within mathematical contexts have received little attention. A major reason is the scarcity of labeled data: there are only two publicly available educational datasets with PII annotations, one consisting of student-authored articles submitted to a massive open online course (MOOC) on critical thinking through design[2] [11] and the other containing teacher–student chatroom messages for English language learning[3] [1]. To our knowledge, no public datasets exist for PII detection in math education contexts.

3. CURRENT RESEARCH OVERVIEW

To answer the research questions outlined above, we follow a three-phase research workflow moving from dataset construction to analytical validation and finally to evaluation of math-aware de-identification strategies.

Phase 1: Dataset Preparation involves constructing MathEd-PII, a benchmark dataset for PII detection in math tutoring context. The construction includes identifying original over-redaction and establishing a clean ground truth through human-in-the-loop LLM-powered PII surrogation.

Phase 2: Math Segmentation focuses on developing a density-based module to isolate math-heavy regions, serving as an analytical lens to validate the hypothesis of numeric ambiguity that false PII redactions are structurally concentrated in mathematical content while true redactions are not.

Phase 3: PII Detection and Evaluation implements and compares four PII detection strategies—a Presidio-based baseline, LLMs with a basic prompt, a general math-domain-aware prompt, and a specific math-segment-aware prompt—evaluating Precision (P), Recall (R), and F1 overall, as well as stratified by PII types and by math versus non-math segments.

4. PHASE 1: DATASET PREPARATION

Reference datasets for PII detection in math education are currently lacking. To enable rigorous evaluation, we constructed a benchmark dataset, **MathEd-PII**, from a PII-redacted large corpus.

4.1 Source Corpus

Our source corpus comprises 1,000 math tutoring sessions (115,620 messages; 769,628 tokens) from a U.S.-based tutoring platform. Among these, 4,648 (4%) messages spread in 786 sessions feature 5,265 PII redactions applied by the platform's in-house PII detection system–Microsoft Presidio, which, as introduced in 2.2, is an industry-standard open-source software development kit (SDK) for PII detection by integrating rule-based recognizers for high-precision patterns with neural-network-based entity detectors within a unified anonymization framework [16] with customizable

[2]Available at https://www.kaggle.com/datasets/langdonholmes/cleaned-repository-of-annotated-pii/data

[3]Available via request at forms.gle/pKc48WMhnySC8zDk9

rules. The provider redacts 12 types of PII, such as PERSON, LOCATION, US_DRIVER_LICENSE, etc. The full list of PII types can be found in Table 6.

Initial inspection suggests that several redaction types are not consistently reliable indicators of true PII in math tutoring dialogue. In particular, some types that resemble structured numeric identifiers (e.g., COURSE_NUMBER and US_DRIVER_LICENSE) are frequently triggered by math content rather than identity disclosure (see an example of incorrect redactions and inferred original text[4] in Table 1). Other types (notably LOCATION, NRP[5], and URL) appear mixed, containing both correct redaction and substantial over-redaction.

Table 1: Incorrect PII Redactions in the Source Corpus and Inferred Original Text

Redacted Message	Inferred Original Message
9351 / 7 = 1335 <US_DRIVER_LICENSE>	9351 / 7 = 1335.8571
go from radians to degrees it would <COURSE_NUMBER>/pi	go from radians to degrees it would 180/pi
so it would be 1.15x= 1.15x=<PHONE_NUMBER>368000	so it would be 1.15x=

4.2 Method: Human-In-The-Loop PII Redaction Evaluation and Surrogate Generation

To evaluate the extent of incorrect redactions and construct a reliable benchmark for PII detection from the current dataset, we employed a human-in-the-loop LLM workflow to assess the quality of existing PII labels and generate plausible surrogates, thereby restoring transcript completeness for downstream investigation. This design choice is motivated by three practical constraints. First, the original un-redacted transcripts are unavailable due to privacy and data-protection requirements, precluding direct comparison against ground-truth PII. Second, manually reviewing and reconstructing every redaction at scale would be prohibitively costly and time-consuming. Third, LLMs are well-suited for this task because they can leverage rich contextual information to infer the most plausible lexical realizations consistent with surrounding discourse, enabling systematic approximation of redacted content without reintroducing real personal identifiers. Human oversight is incorporated throughout the workflow to validate model outputs, refine prompts, and ensure that generated surrogates remain contextually coherent while preserving privacy. This workflow consists of the following three steps and is illustrated in Figure 1.

First, **Initial LLM-Based Assessment**: We first drafted an initial prompt that instructed the LLM to evaluate messages from a randomly sampled set of 100 transcripts, using a context window of at least three utterances preceding and following each target message. For each message, the LLM was prompted to identify any redacted PII or PII missed by the data provider's internal redaction process, determine its PII type, and classify the redaction as "PII", "Not PII", or "Uncertain" based on contextual evidence. When PII was identified, the LLM was further instructed to generate context-appropriate surrogate text that preserved semantic coherence while remaining substantially different from any original PII, when available.

Second, **Human-In-The-Loop Validation and Refinement**: Three researchers—the first three authors of this paper—then manually reviewed the LLM outputs. Each researcher was assigned one-third of the outputs and down-voted instances in which any component of the output was deemed incorrect, including the identified PII type, quality classification, or the generated surrogate. Based on these annotations, the prompt was revised iteratively to address observed failure modes. This process continued until at least 95% of previously down-voted issues were successfully resolved by the updated prompt.

Third, **Pipeline Execution at Scale**: The final, validated prompt[6] for redaction evaluation and surrogate generation was subsequently applied to the full 1,000-transcript dataset to produce the benchmark used in downstream analyses.

All three steps were conducted using an open-sourced annotation web application, Sandpiper[7], optimized for stable, human-in-the-loop annotation iteration. The system provides a robust, interactive user interface that allows researchers to directly review, up-vote, or down-vote AI-generated annotations, enabling efficient human verification and correction at scale. Its modular architecture and worker-based execution model ensure stable handling of large annotation workloads and repeated LLM inference, supporting consistent evaluation across iterations.

4.3 Source Corpus Evaluation Results

Applying the procedures described above, we discovered both recall and precision issues of the data provider's internal PII redaction presented in the source corpus as described below.

The Recall Issue: The human-in-the-loop LLM workflow discovered 201 messages containing PII that the data provider's system failed to redact, spanning PERSON (159), GRADE_LEVEL (23), AGE (8), DATE (4), COURSE_NUMBER (3), NRP[8] (3), SCHOOL (2), and URL (1). Notably, DATE and AGE were newly introduced PII types under the Safe Harbor framework (see Section 2.1) and were not included among the original dataset's 12 PII categories. Still, this demonstrates a substantial recall issue: a widely used approach to de-identification, Microsoft Presidio, failed to identify 159 names in tutoring transcripts. Table 2 presents simulated examples of missed names. These examples were generated from failure patterns observed in the original dataset and do not refer to any real

[4]Original un-redacted text is not available due to the data provider's privacy compliance. The original text here is inferred by an LLM based on the context. Please see Section 4.2 for more details.

Table 2: Simulated Examples of `PERSON` that Presidio Failed to Detect and Similar Cases that Presidio Successfully Detected

Unsuccessful Detection	Successful Detection
hey olivia	hey Olivia
Hi Alex	Hi Alex,
I am Lam	i am Lam

The Precison Issue: Of the 4,648 originally redacted messages, 3,015 (64.87%) contained redactions evaluated as "Not PII", indicating low precision in their internal system. Several PII types contained predominantly false positives, with the following four types receiving more than 90% "Not PII" flags–`US_DRIVER_LICENSE` (99.36%), `COURSE_NUMBER` (96.65%), `PHONE_NUMBER` (93.33%), and `NRP` (90.64%), the first three of which are all numeric identifiers further corroborating our initial findings. Table 1 presents some examples of such over-redaction.

4.4 The MathEd-PII Surrogate Benchmark

By replacing all of the originally redacted PII and newly identified PII with LLM-generated, context-aware surrogates and removing PII annotations for those that were labeled as "Not PII", we obtained the MathEd-PII surrogate benchmark dataset. A comparison of basic statistics for the source corpus and MathEd-PII is presented in Table 3.

Table 3: PII Statistics Comparison between Source Corpus and MathEd-PII (ordered by the most common PII to the least in MathEd-PII)

Category	Source Corpus	MathEd-PII

5. PHASE 2: MATH SEGMENTATION AND NUMERIC AMBIGUITY

Since major "Not PII" redactions are numeric identifiers, a natural explanation is *numeric ambiguity*: mathematical content in tutoring transcripts often shares surface-level similarities with numeric PII, making the two difficult to distinguish. Assessing the extent to which numeric ambiguity degrades PII detection—and developing effective mitigation

strategies—therefore requires distinguishing math-dense regions from non-mathematical conversational text.

5.1 Method: Math Density, Semantic Similarity, and Segmentation Optimization

To distinguish math-focused sections in a transcript, we applied a segmentation strategy by first identifying anchor math messages with high density of math vocabulary and then expanding the segment based on semantic similarity [5, 13, 20].

The construction of the math vocabulary set was informed by a comprehensive list of 2,824 K-12 math learning components[9] curated by the Learning Commons initiative and the Achievement Network [15], which are granular representations of individual math skills and concepts encompassing the Common Core State Standards for Mathematics (CCSSM) and 18 U.S. state math standards (e.g., California, New York, Texas, and Washington). Some examples of the learning components are "Use conversions to solve multi-step real-world problems", "Determine the lateral surface area of three-dimensional cylinders in real-world problems", and "Represent proportional relationships with equations". The math vocabulary used for math density calculation includes a list of math terms derived from these learning components and regular expressions (RegEx) of common math expressions. The vocabulary can be found here[10].

The **Math Density** (D_{math}) of a message is a weighted sum of single-word math vocabulary terms (V_{math}), multi-word phrases (P_{phrase}), and RegEx patterns ($R_{pattern}$):

$$D_{math}(m) = \frac{1}{|W|}\left[\sum_{w\in W}\mathbb{I}(w \in V) + 1.5\sum_{p\in P}C(p,m) + 2.0\sum_{r\in R}C(r,m)\right] \quad (1)$$

where W is the set of tokens in the message, $\mathbb{I}(\cdot)$ is the indicator function, $C(\cdot, m)$ counts Occurrences in message m. The weights were empirically set to attribute higher significance to multi-term concepts and structural math patterns.

A message exceeding a threshold of Math Density, *Anchor Threshold* (T_{anchor}) at 0.05, becomes an anchor message and initializes a math segment. Adjacent messages are added to the math segment if their cosine similarity to the segment centroid (the aggregated semantic meaning of the math context accumulated in the segment computed via `all-MiniLM-L6-v2` embeddings) exceeds a *Similarity Threshold* (T_{sim}) at 0.3. The thresholds were determined via a grid search optimization process around the average math density of the dataset (0.07) from 0.05 to 0.10 in increments of 0.01 and a range of similarity threshold from 0 to 0.5 with a step size of 0.1 with the objective to maximize the capture of "Not PII" (false positives) and minimize the capture of "PII" (true positives) by the math segments. Notably, across all threshold configurations evaluated in the grid search, the proportion of false positives consistently exceeded the proportion of true positives captured by the math segments. This indicates that the finding elaborated below is robust to the choice of threshold. The optimization process and analysis can be seen here[11].

5.2 False Positive PII in Math Segments and Numeric Ambiguity

Figure 2 illustrates the distribution of PII categories across mathematical and non-mathematical segments, distinguishing between true positives (validated PII) and false positives (Not PII) arising from numeric ambiguity.

It reveals a stark contrast in detection accuracy between the two domains. In math segments, the data provider's in-house detection system produced 2,539 false positives compared to only 520 true PII instances—a false-to-true ratio of approximately 4.88:1. In contrast, non-math segments exhibited a much higher precision, with 929 false positives and 1,455 true PII instances (a ratio of 0.64:1).

Specific numeric categories were nearly entirely composed of false positives in mathematical contexts. For instance, as shown in the MATH Segment of Figure 2, categories such as `DATE`, `US_DRIVER_LICENSE`, and `LOCATION` contain substantial numbers of false positives. Interestingly, the `PERSON` category also presents a high number of false positives within math segments. Qualitative review indicates that these names are frequently tied to mathematical word problems (e.g., "If Alex has 5 apples...") rather than the actual identities of the student or tutor. While over-redacting these fictional entities is perhaps less detrimental to educational utility than over-redacting the mathematical operations themselves, it further illustrates the inability of domain-agnostic systems to distinguish between the *context* of a name (math problem vs. personal disclosure).

This empirical evidence confirms that numeric ambiguity is a structural failure mode in de-identifying math tutoring transcripts: the surface forms of mathematical expressions and problem-related entities systematically overlap with structured personal identifiers, leading generic detection systems to over-redact critical instructional content.

6. PHASE 3: PII DETECTION AND EVALUATION

6.1 PII Detection Methods

6.1.1 Baseline: Microsoft Presidio

As a baseline, we deployed Microsoft Presidio (v2.2) [16]. We utilized its default analyzer which orchestrates a set of predefined recognizers. For high-structure entities (e.g., `EMAIL_ADDRESS`, `URL`, `IP_ADDRESS`, `PHONE_NUMBER`, `US_SSN`, `US_DRIVER_LICENSE`), Presidio employs regular expressions (RegEx). For context-dependent entities (e.g., `PERSON`, `LOCATION`, `NRP`), it leverages a spaCy-based NER model (`en_core_web_lg` and `en_core_web_trf` used here). To address domain-specific requirements, we implemented custom RegEx-based recognizers for `SCHOOL`, `COURSE_NUMBER`, and

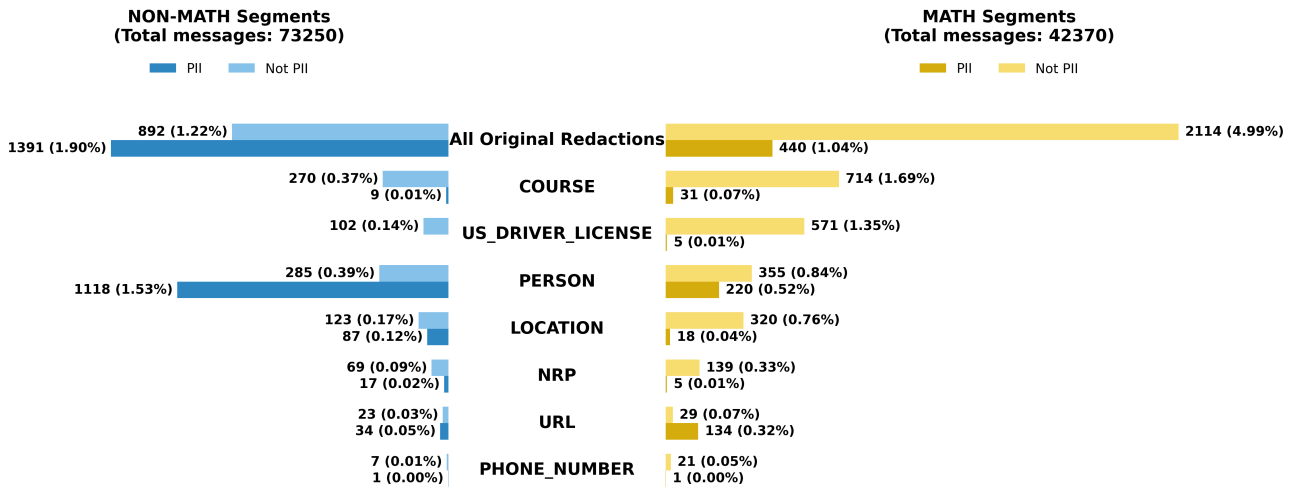

Figure 2: Distribution of Original PII Redactions from the Data Provider's In-House System (Presidio and Customized Rules) across Different PII Types and Math and Non-Math Segments in terms of true PII and false positives ("Not PII"). Types are ordered by the frequency of "Not PII" in Math Segments. The first seven types are presented.

`GRADE_LEVEL`. We mapped Presidio's output entities to the 17 target PII categories.

6.1.2 *LLMs using Basic, Math-Aware, and Segment-Aware Prompts*

We evaluated the performance of six LLMs—Claude 4.5 Haiku, Claude 4.5 Opus, GPT-4 Turbo, GPT-5.2, Gemini 2.5 Flash, and Gemini 3 Pro—on the task of PII detection to examine the robustness of LLM-based methods. These models were selected because they are widely used and span lightweight, general-purpose, and high-capability model regimes. To ensure data security and compliance, all API requests were routed through Cornell University's LLM Gateway, LiteLLM[12]. This centralized gateway provides a unified interface while enforcing strict privacy protocols; crucially, it operates under a zero-retention policy where payload data is neither logged by the gateway nor used for model training, aligning with institutional IRB requirements.

We first compared model performance under basic prompting against the baseline and selected the higher-performing model from each provider for subsequent evaluation with the math-aware and segment-aware prompting strategies, in order to assess whether these refinements further improve PII detection performance. The three prompt variants are described below.

Basic Prompt: A straightforward instruction acting as a PII specialist. It lists the 17 PII categories and requests the model to identify "ALL PII" in the message, returning a JSON list of text spans and types (exact text here[13]).

Math-Aware Prompt: A refined version of the basic prompt that explicitly addresses the domain challenge. This prompt aims to reduce false positives stemming from numeric ambiguity by leveraging the model's general knowledge about math tutoring (exact text here[14]).

Segment-Aware Prompt: A refined version of the basic prompt that explicitly points to the math segment label for each message. This prompt aims to reduce false positives stemming from numeric ambiguity through explicit contextual grounding (exact text in here[15]).

6.1.3 *Evaluation Metrics and Statistical Analysis*

We evaluated PII detection performance using standard metrics: Precision, Recall, and the F1-score. Precision measures the proportion of detected text spans that correctly match the ground truth, Recall indicates the proportion of actual PII spans successfully identified, and the F1-score represents their harmonic mean. To account for the inherent variability and potential clustering of errors within different tutoring sessions, we calculated 95% confidence intervals (CIs) using a bootstrap resampling method. We performed 1,000 bootstrap iterations by resampling tutoring transcripts (the primary unit of our corpus) with replacement. For each iteration, metrics were aggregated across the resampled sessions. The 95% CIs reported in our results correspond to the 2.5th and 97.5th percentiles of the resulting bootstrap distribution.

6.2 PII Detection Performance

6.2.1 *Overall Performance*

Table 4 summarizes the performance of Microsoft Presidio (baseline) and various LLMs using three types of prompts.

The baseline Presidio models achieved high recall (with the

Claude 4.5 Opus	0.911 [0.861, 0.946]	0.730 [0.677, 0.783]	0.810 [0.762, 0.853]
Gemini 2.5 Flash	0.848 [0.806, 0.887]	0.771 [0.723, 0.818]	0.807 [0.769, 0.844]
Gemini 3 Pro	0.887 [0.863, 0.910]	0.760 [0.706, 0.812]	0.818 [0.781, 0.851]
GPT-4 Turbo	0.732 [0.695, 0.769]	0.578 [0.530, 0.630]	0.646 [0.609, 0.685]
GPT-5.2	0.759 [0.723, 0.795]	0.707 [0.656, 0.759]	0.732 [0.695, 0.767]
Math-Aware Prompting			
Claude 4.5 Opus	0.905 [0.860, 0.938]	0.720 [0.661, 0.769]	0.802 [0.756, 0.842]
Gemini 3 Pro	0.869 [0.826, 0.906]	0.735 [0.685, 0.787]	0.796 [0.756, 0.835]
GPT-5.2	0.774 [0.740, 0.809]	0.721 [0.670, 0.764]	0.747 [0.711, 0.780]
Segment-Aware Prompting			
Claude 4.5 Opus	**0.934** [0.913, 0.951]	0.730 [0.682, 0.784]	0.820 [0.785, 0.855]
Gemini 3 Pro	0.888 [0.862, 0.913]	0.764 [0.713, 0.811]	**0.821** [0.788, 0.851]
GPT-5.2	0.800 [0.760, 0.838]	0.720 [0.670, 0.766]	0.758 [0.720, 0.793]

Transformer version reaching a point estimate of 78.1%), but suffered from exceptionally poor precision (spanning 0.23–0.25). This confirms that generic PII detection tools tend to over-redact math-rich content by failing to distinguish mathematical notation from sensitive identifiers. While the point estimates for Presidio's recall appear high, several top-performing LLMs achieved recall levels that are statistically comparable (with overlapping 95% bootstrap confidence intervals) while providing vastly superior precision and F1 scores. Based on these initial results, Claude 4.5 Opus (Anthropic), Gemini 3 Pro (Google), and GPT-5.2 (OpenAI) were selected as the primary focus for evaluating domain-specific prompt refinements.

Math-aware prompting generally improved the precision of the selected models compared to the basic prompt across most configurations. Segment-aware prompting, which explicitly grounds the detection process in the mathematical context of the message, yielded the highest overall performance for all three models. Notably, Claude 4.5 Opus achieved the highest precision (0.934, 95% CI [0.913, 0.951]) under this condition, while Gemini 3 Pro achieved the highest overall F1 score (0.821, 95% CI [0.788, 0.851]). Crucially, the segment-aware versions of these models maintain recall levels that are on par with the baseline, while reducing false positives by as much as 90%. These results demonstrate that incorporating mathematical discourse context is essential for minimizing over-redaction.

6.2.2 Performance by PII Categories

Given that both the baseline and the top-performing LLMs achieved comparable recall levels (as discussed in the previous section), we zoom in on category-level performance to investigate how domain-aware prompting reduces false positives to achieve superior precision. Table 5 provides a breakdown of the specific sources of over-redaction, focusing on False Positives (FP) and Precision across the target PII categories under two model configurations: the highest-performing baseline, Presidio LG (using the `en_core_web_lg` SpaCy NER model), and the highest-performing LLM configuration, Gemini 3 Pro with segment-aware prompting.

Table 5: PII Detection False Positives and Precision by Category (ordered by Precision from the highest to the lowest from Gemini 3 Pro with Segment Prompting)

PII Type	Total	Presidio LG		Gemini 3 Pro Seg.	
		FP	Prec	FP	Prec
US_DRIVER_LICENSE	2	344	0.000	0	1.000
PERSON	1422	330	0.775	63	0.949
LOCATION	121	153	0.349	5	0.896
NRP	25	45	0.286	2	0.857
URL	187	21	0.859	21	0.852
SCHOOL	73	17	0.638	10	0.831
GRADE_LEVEL	103	2	0.973	22	0.750
IP_ADDRESS	2	0	1.000	1	0.667
PHONE_NUMBER	2	6	0.250	1	0.667
AGE	8	3	0.000	6	0.538
COURSE_NUMBER	40	46	0.193	43	0.411
DATE	3	3386	0.001	16	0.059
US_BANK_NUMBER	0	5	0.000	-	-

The most striking improvement is observed in numeric categories where the baseline is particularly prone to over-redact mathematical entities. For instance, Presidio generated 3,386 false positives for `DATE` and 344 for `US_DRIVER_LICENSE`, confirming that rule-based systems frequently misinterpret math spans as structured identifiers. In contrast, Gemini 3 Pro with segment-aware prompting reduced `DATE` false positives by over 99.5% (down to 16) and eliminated false positives for `US_DRIVER_LICENSE` entirely. Similarly, for context-heavy categories like `PERSON` and `LOCATION`, the LLM significantly improved precision by reducing the number of false detections. These results underscore that the superior performance of domain-aware LLMs is primarily driven by their ability to selectively filter mathematical noise while maintaining a capture rate on par with standard tools.

6.2.3 Performance by Segment Types

To further investigate how well the LLM addressed numeric ambiguity, we evaluated model performance separately for messages labeled as NON-MATH versus MATH conversational segments. Table 6 reveals a consistent performance gap across the models, with precision being systematically lower in the MATH segment compared to the NON-MATH segment.

The stratified analysis in Table 6 provides strong empirical evidence for the numeric ambiguity hypothesis and demonstrates the effectiveness of segment-aware prompting in mitigating it. The baseline Presidio LG model exhibits a big drop in precision when moving from NON-MATH (0.346) to

Table 6: PII Detection Performance by Segment Type (NON-MATH vs. MATH)

Model	Prompt	NON-MATH Segments			MATH Segments		
		Prec	Rec	F1	Prec	Rec	F1
Presidio LG	-	0.346	0.756	0.475	0.142	0.720	0.237
Gemini 3 Pro	Basic	0.913	0.819	0.864	0.800	0.591	0.680
Gemini 3 Pro	Segment	0.909	0.815	0.860	0.819	0.618	0.705

MATH segments (0.142), confirming that generic rule-based systems frequently misinterpret mathematical notation as sensitive identifiers. This 59% decline in precision within math-dense regions highlights the risk of over-redaction in tutoring transcripts when domain context is ignored.

In contrast, the Gemini 3 Pro model maintains substantial precision in both contexts, though a performance gap between segments remains. Crucially, the introduction of segment-aware prompting specifically improves the model's ability to navigate numeric ambiguity within mathematical discourse. In MATH segments, segment-aware prompting increases both precision (0.800 to 0.819) and recall (0.591 to 0.618) compared to basic prompting. This simultaneous gain in both metrics is particularly noteworthy; it suggests that providing the model with an explicit context label allows it to adopt a more nuanced decision boundary—correctly identifying PII that it might otherwise miss (higher recall) while simultaneously avoiding false detections triggered by mathematical symbols (higher precision). The negligible difference in performance within NON-MATH segments further indicates that the benefits of this strategy are structurally concentrated in the regions where numeric ambiguity is most severe.

7. DISCUSSION AND CONCLUSION

This study investigated the challenge of utility-preserving de-identification in the context of math tutoring transcripts, focusing on the phenomenon of numeric ambiguity. By introducing MathEd-PII, the first benchmark dataset for this domain, we provided a rigorous foundation for evaluating PII detection methods that balance privacy protection with instructional fidelity.

Our findings provide strong empirical evidence that numeric ambiguity is a structural failure mode in standard PII detection systems. Generic tools like Microsoft Presidio often misinterpret mathematical expressions as sensitive identifiers, such as dates or driver's license numbers. Our density-based segmentation analysis revealed that over half of all false positives (55.5%) were concentrated in math-dense regions, which comprise only about a third of the corpus tokens. In these regions, the ratio of false positives to true PII reached nearly 5:1, highlighting a significant risk of removing core instructional content that is essential for educational research.

We demonstrated that LLMs, particularly when guided by domain-aware prompting strategies, significantly outperform traditional baselines. While Presidio achieved a respectable recall, its low precision (F1: 0.380) renders it problematic for creating high-utility datasets. In contrast, Gemini 3 Pro with segment-aware prompting achieved an F1 of 0.821, maintaining high recall while reducing false positives by over 90% in critical numeric categories. The success of segment-aware prompting suggests that providing models with explicit contextual grounding—identifying whether a message is likely to be mathematical—allows them to adopt more nuanced decision boundaries that better distinguish task-content from personal disclosure.

The creation of MathEd-PII through a human-in-the-loop LLM surrogation workflow also offers a methodological contribution. It demonstrates how high-quality benchmark data-sets can be generated even when original, unredacted data cannot be directly shared, by leveraging the generative capabilities of LLMs to create privacy-preserving surrogates that maintain discourse coherence.

However, several limitations and avenues for future work remain. First, while MathEd-PII is the first math-focused PII surrogate benchmark, it is based on 1,000 sessions from a single U.S.-based tutoring platform. As a result, the generalization behavior of the proposed methodology across broader educational domains remains an open question. Expanding this benchmark to include more diverse curricula, grade levels, instructional settings, and international contexts would improve the generalizability of our findings and enable more systematic evaluation across heterogeneous datasets. More broadly, our approach to ensuring applicability across different contexts is to emphasize domain-aware prompting principles that are adaptable to new educational settings, while future work will focus on validating these strategies on additional datasets and subject areas beyond mathematics tutoring.

Second, while this work focused primarily on addressing the precision issues caused by numeric ambiguity, further optimizing recall remains an important avenue for future exploration. Although our domain-aware prompting strategies yielded substantial improvements in F1 and maintained recall levels comparable to standard baselines, a portion of PII still remains undetected. While a detailed investigation into maximizing recall was beyond the scope of this paper, there are several promising directions to bridge this gap, such as: (1) developing multi-stage "cascade" architectures that combine high-recall rule-based systems with high-precision LLM verification; (2) exploring advanced prompting techniques like multi-agent debate to enhance sensitivity to subtle PII mentions; and (3) leveraging the MathEd-PII dataset to fine-tune specialized models that capture domain-specific patterns more effectively and robustly than prompt-only approaches. In addition, the current methodology relies entirely on prompting large language models, which may be brittle across model versions, prompting styles, or unseen distributions. Fine-tuning specialized domain-adapted models therefore represents an important future direction for improving robustness, consistency, and transferability across datasets and deployment settings. Finally, future work could also investigate making these solutions more efficient for low-cost, on-device deployment at educational institutions.

In conclusion, as dialogue-based interaction data becomes increasingly available to educational data mining community, the need for domain-aware de-identification becomes paramount. This work shows that by incorporating mathe-

matical context into the de-identification pipeline, we can move closer to the goal of "utility-preserving privacy"—protec-ting student and tutor identities without sacrificing the very data that makes educational research possible.

ABSTRACT

Voice-based AI systems are increasingly used for L2 speaking practice, but evaluations rarely characterize the interactional processes they create. We analyze 78 university learners of German across four sites completing a counterbalanced spot-the-difference task with both a human peer and a real-time AI partner. From diarized ASR transcripts, we extract measures of interactional fluency, linguistic uptake, and learner experience. Human dialogue was faster and more balanced, with many short turns; AI dialogue resembled supported monologue, with fewer, longer turns, reduced learner floor share, and greater within-turn fluency. The AI's verbose, syntactically regular input was associated with greater short-term uptake and stronger syntactic priming after controlling for input volume. Attitudes toward AI improved after the task, and satisfaction was predicted by production fluency rather than uptake. The results show complementary affordances for AI and human dialogue in L2 practice.

Keywords

interactional fluency, L2 speech, voice-based AI, turn-taking, educational data mining

1. INTRODUCTION

Voice-based conversational AI is increasingly positioned as a scalable speaking partner for second language (L2) learners. Yet these systems do not simply provide more practice, they change the *nature* of the interaction [1, 2, 29, 11, 22]. AI-based interlocutors, especially using large language models (LLMs), produce longer turns, respond at atypical moments, and lack the backchannels and floor-negotiation strategies of human partners [22, 29, 11, 30, 5]. If interaction structure shapes learning opportunities, then characterizing *how* AI-mediated dialogue differs from human dialogue is essential for informed system design and deployment.

Most evaluations of dialogue-based computer-assisted language learning (CALL) focus on outcome measures: pre/-post speaking scores, perceived confidence, or learner satisfaction. Meta-analytic evidence confirms positive effects overall but highlights substantial heterogeneity across systems, tasks, and evaluation criteria [2, 17, 10]. What remains underexplored is the *interactional process* itself—how learners and systems jointly construct spoken interaction during practice [19].

We address this gap through three complementary lenses. The first is *interactional fluency*: measurable properties of conversational coordination—response latency, turn-length distributions, floor sharing, and within-turn pausing—that reflect how speakers manage participation in real-time dialogue. While the distinction between monologic and dialogic fluency is well established in SLA research [38], less is known about how these dynamics shift when the interlocutor is a machine.

The second is *linguistic uptake*. Conversational alignment theory holds that interlocutors converge on lexical and syntactic forms during interaction [28], a process proposed as a mechanism supporting L2 learning [6, 23]. When partners differ fundamentally in how they generate language, it is an open question whether they afford similar uptake opportunities. We operationalize this as direction-sensitive lexical and morphosyntactic uptake: the extent to which a learner reuses words or constructions introduced by the interlocutor in the preceding context.

The third is *learner experience*. If AI and human dialogue create different interactional conditions, learners may perceive these differences, and the behavioral features of the interaction (e.g., production fluency, floor balance) may predict satisfaction independently of what learners linguistically adopt.

These three lenses motivate the following research questions:

RQ1: How do **interactional fluency** measures differ between human–human and human–AI dialogue?

RQ2: Do learners differ in **lexical and morphosyntactic uptake** from a human partner versus an AI-interlocutor, and do these differences vary across linguistic levels?

RQ3: How do learner **attitudes toward AI** change after direct experience, and what behavioral features of the interaction predict satisfaction?

To investigate these questions, we conducted a controlled, multi-site study with second- and third-year L2 German learners ($N = 78$) at four universities in the United States and Europe. Participants completed a spot-the-difference task under four within-speaker conditions: two monologic scene descriptions and two dialogues (one with a human peer, one with a real-time AI partner). All measures are extracted from diarized, timestamped ASR transcripts without manual coding. Results reveal two distinct interaction modes: human dialogue is rapid and balanced, whereas AI dialogue resembles a supported monologue, with fewer but longer turns, slower responses, reduced learner floor share, and greater within-turn fluency. AI verbosity and syntactic regularity afford more uptake opportunities, and learners show stronger short-term syntactic priming with the AI partner even after controlling for input volume. Attitudes toward AI improve after the task, with satisfaction tied to production fluency rather than linguistic uptake.

This paper makes three contributions: (1) we operationalize interactional fluency and direction-sensitive uptake for spoken AI practice using metrics extractable from diarized ASR output without manual linguistic annotation; (2) we leverage a within-speaker design across four instructional sites to isolate how the same learner's interaction changes with a human versus AI partner; and (3) we provide a reusable analysis pipeline for rapid, scalable evaluation of conversational AI in educational settings. The remainder of the paper describes the study design (§3), methods and results for interactional fluency (§4.1), uptake (§4.2), and survey analyses (§5), followed by discussion and design implications (§6).

2. RELATED WORK

Prior work establishes the promise of conversational practice for language learning, but also suggests that who (or what) the interlocutor is can reshape the interaction itself.

Conversational practice and transcript-based measurement. Dialogue-based computer-assisted language learning (CALL) has a long history motivated by the role of interaction in second language development. Meta-analytic evidence suggests that dialogue-based CALL systems can yield positive learning outcomes overall, while also reporting substantial heterogeneity across system types, tasks, and evaluation measures [2]. Recent reviews of conversational agents for language learning echo both pedagogical promise and persistent concerns about reliability, pedagogical alignment, and evaluation practices [17, 10]. As voice-based LLM systems become plausible speaking partners, a central question is not only whether learners improve, but what kinds of interaction these systems create and how those interactional properties shape practice opportunities [19].

A parallel development in learning analytics is the growing treatment of dialogue as analyzable behavioral trace data. This shift enables process-level evaluation of learning-support interactions, but it also raises a practical challenge for spoken settings: extracting reliable measures without extensive manual annotation. Recent work demonstrates that transcript-based pipelines can extract educationally meaningful structure from naturalistic collaborative speech, enabling scalable, fine-grained analysis [39]. This line of work motivates our use of diarized, timestamped transcripts to quantify interaction dynamics and linguistic behavior across interlocutor conditions and sites.

Interactional fluency and turn-taking with AI partners. Within second language acquisition (SLA) research, fluency is often decomposed into speed, breakdown, and repair, and dialogic fluency work argues that monologic temporal measures can miss key interactional phenomena in conversation [38]. Overlap, interruptions, and between-turn gaps can materially affect fluency assessments, motivating measurement at the level of turns and turn transitions. Pauses, repetitions, and stalling may likewise function as interactional resources rather than purely as disfluency [25]. These perspectives build on classic accounts of turn-taking norms that describe strong pressure to minimize gaps and avoid overlap, with response latency as a central coordination variable [33, 37, 20].

When one interlocutor is a machine, these norms can shift systematically. Studies of voice interfaces document altered turn design and recurring breakdown and repair patterns [29, 21], and users may perform additional interactional work to maintain progressivity when systems are slow or insufficiently contingent [11]. With LLM-based agents, system contributions become more content-rich, yet interface timing and modality still constrain turn-taking and repair; users often scaffold the interaction through reformulations and related strategies [30]. Emerging work in language learning contexts suggests that L2 learners' turn-taking practices may shift when interacting with conversational AI [5]. Interaction structure is also increasingly treated as consequential for learning processes, with dialog acts in AI-supported peer tutoring linked to learning rates [3]. Together, these strands motivate our analysis of interactional fluency as a way to characterize how human–AI dialogue differs from human–human dialogue in the interactional conditions it affords.

Lexical and morphosyntactic uptake as alignment in dialogue. Psycholinguistic theories of alignment propose that interlocutors tend to converge on lexical and syntactic representations through priming mechanisms, supporting efficient coordination [28]. Related work on lexical entrainment and conceptual pacts shows how partners establish shared referring expressions as part of building common ground [4]. In SLA, alignment has been proposed as a mechanism that can support learning, since repeated exposure to and reuse of forms in interaction may increase accessibility and entrenchment [6, 23], and empirical work suggests that alignment patterns vary with interactional context [6, 18]. In the present one-shot design, we therefore treat uptake as short-term mining or alignment, not as evidence of durable

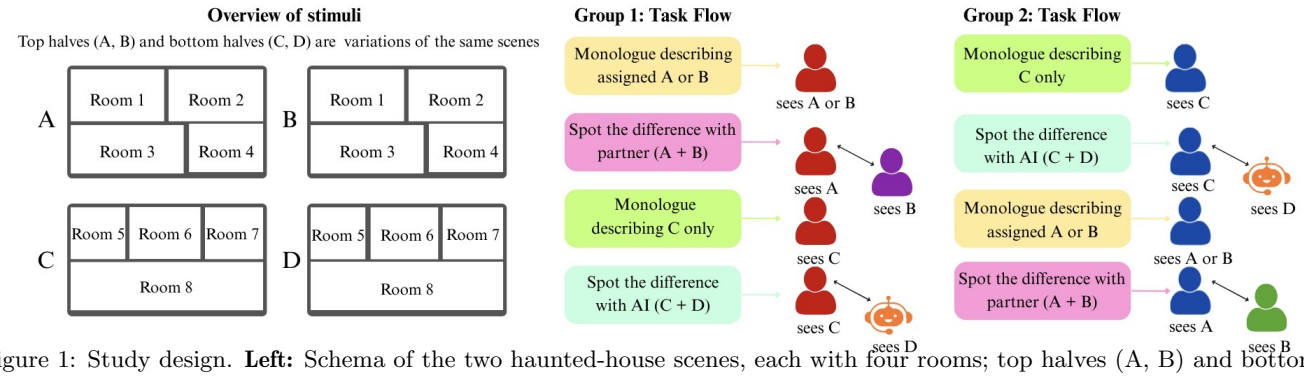

Figure 1: Study design. **Left:** Schema of the two haunted-house scenes, each with four rooms; top halves (A, B) and bottom halves (C, D) are slight variations of the same scenes. In the human condition each partner sees a different version (A or B), while in the AI condition the participant describes C and the AI is provided a description of D. **Right:** Task flow for the two counterbalanced groups. Each participant completes four tasks: two monologues and two dialogues (one with a human partner, one with the AI). Group 1 completes the human block first; Group 2 completes the AI block first.

learning; repeated alignment may provide affordances for learning over time, but our data measure immediate reuse opportunities rather than acquisition.

Measuring alignment at scale remains challenging. However, computational dialogue research offers measures ranging from global similarity to targeted accounts of repetition and construction reuse [32]. Work in human computer interaction further shows that people align their language with spoken dialogue systems, and that the strength and form of this alignment can vary with system framing and design [7, 35]. Educational natural language processing has also moved toward turn-linked measures that capture responsiveness beyond surface similarity [9]. Recent work similarly demonstrates the feasibility of automated, language-based measurement in educational settings, including LLM-based detection of learning-relevant constructs in verbal protocols [41]. At the same time, these approaches foreground familiar concerns about construct validity and fairness in model-based inference [36]. Building on these threads, we operationalize lexical and morphosyntactic uptake as a direction-sensitive form of alignment, measuring the extent to which learners reuse lexical items and morphosyntactic patterns introduced by the interlocutor in the immediately preceding context.

Learner affect and attitudes. CALL studies of chatbot and LLM-based speaking practice frequently include self-report measures—perceived usefulness, enjoyment, comfort, willingness to communicate—since these perceptions shape sustained engagement [17, 12]. Recent work shows that some conversational AI designs can increase willingness to communicate and reduce speaking anxiety [40], and that perceived enjoyment and satisfaction predict intentions to continue using AI tools for speaking practice [16]. However, these attitudinal outcomes are rarely connected to fine-grained interaction traces, leaving open which moment-by-moment behaviors drive learner perceptions—a gap we address by relating survey responses to transcript-derived interaction metrics.

3. DATA COLLECTION

3.1 Task and Stimuli

Participants completed a spot-the-difference task, a cooperative information-gap activity widely used in communicative language teaching [27]. A human artist created a "haunted house" scene containing eight rooms, each drawn in two matched versions with systematic differences in object placement (e.g., repositioned ghosts, added or removed objects). Participants communicated in the L2 language to identify these differences. The eight rooms were roughly matched for complexity and divided into two sets of four; one set was used for the human dialogue condition and one for the AI dialogue condition. Figure 1 provides an overview of the study design.

3.2 Conditions and Procedure

The study used a within-participant design with four speaking conditions along two dimensions: (i) task format (monologue vs. dialogue) and (ii) partner type (human peer vs. AI model).

Participants were assigned to a counterbalanced design, with one group completing the human–human condition first and the other completing the human–AI condition first. In the human-human condition, participants first completed a monologue describing either image A or image B, and then engaged in a dialogue about the same room set with a human partner who had previously described the complementary version. In the human-AI condition, all participants first described image C, followed by a dialogue with the AI system, which was provided a textual description of image D.

In human dialogues, participants were paired with a classmate and completed the task face-to-face or on Zoom; no constraints on turn-taking or strategy were imposed. AI dialogues were conducted through a web application with audio input. This modality asymmetry is representative of how each mode would typically be deployed, but co-presence in the human condition provides non-verbal coordination cues unavailable in the AI condition. Each session lasted approximately 90 minutes including a background survey, vocabulary assessment, the four speaking tasks, and a post-task survey. Data were collected between October and December 2025.

All procedures were approved by the institutional review boards at the participating sites. Before completing the background survey and speaking tasks, participants provided informed consent for audio recording and transcript-based analysis; recordings without valid consent were excluded.

3.3 AI Interlocutor System

We developed the AI system using OpenAI's `gpt-realtime` model[1], selected for its native speech-to-speech capability (eliminating separate ASR/TTS latency), support for a plurality of languages, and real-time turn-taking via server-side voice activity detection. Because direct image input produced excessive hallucination during piloting, we provided the AI with manually verified English-language text descriptions of each room, written by the research team and checked against the images for accuracy. This choice kept the AI grounded in the task materials but creates a stimulus-representation asymmetry: human partners viewed images directly, whereas the AI received textual descriptions of the rooms.

At session initialization, all room descriptions were included in the system prompt[2]; at each room transition, the current room's description was re-sent. The AI retained full conversation history within a session.

The system parameters were set as follows: voice `alloy`, temperature 0.8, max response tokens 150. Turn-taking used server-side VAD with an open microphone (prefix padding 300 ms, silence threshold 200 ms). After pilot testing, we found it useful to instruct the AI model to use informal register, take short turns (one to two sentences), allow time for learner responses, and avoid excessive praise. Despite these constraints, the AI consistently occupied a larger share of the conversational floor than human partners.

3.4 Participants

All participants were enrolled in second- or third-year university German courses at one of four sites: two Flemish universities in Belgium ($n = 24, 34$), a Midwestern US university ($n = 14$), and a Pacific Northwest US university ($n = 14$), totaling $N = 86$. After excluding non-consented, failed, and incomplete recordings, $N = 78$ participants remained, yielding 78 AI dialogues and 39 human-human conversations (one per dyad). Per-analysis sample sizes vary by minimum-turn thresholds and are reported with each analysis. Approximately 50% of participants listed Dutch as their sole L1, English was the second largest group (34.5%), and the remaining 15% comprised speakers of Romanian, Vietnamese, Spanish, Albanian, Hindi, and Ndebele, several of whom reported bilingual combinations with Dutch.

3.5 Transcription

We analyze diarized transcripts rather than raw audio, a deliberate choice favoring scalability: transcript-based measures avoid prosodic confounds across L1 backgrounds and recording environments, require no manual coding, and yield an easily replicable pipeline.

All sessions were transcribed using ElevenLabs `scribe_v2` with automatic speaker diarization (language: `deu`), producing word-level timestamps and speaker attribution. German-speaking authors reviewed all transcripts, verifying speaker labels, trimming non-task speech at recording boundaries, and confirming coherence with assigned room content. Word-level ASR errors were not systematically corrected. In three AI-dialogue transcripts, mid-stream speaker label swaps were detected via an automated disfluency-rate classifier (the AI produces zero filled pauses) and corrected manually.

4. METHODS

From the diarized, timestamped transcripts we extract two complementary sets of metrics. *Interactional fluency* (§4.1) captures how speakers coordinate in real time – how long they hold the floor, how quickly they respond, and how much they hesitate within turns. *Linguistic uptake* (§4.2) captures what speakers do with the language they hear – whether they adopt vocabulary or reproduce morphosyntactic patterns from the interlocutor's speech. The first captures *how* learners interact; the second captures *what language* they take away from the interaction.

4.1 Interactional Fluency

Dialogue involves continuous coordination over who speaks, for how long, and when transitions occur. These properties can differ systematically between human and AI partners, shaping the kind of practice an interaction affords. We capture this through seven features extracted from word-level timestamps, organized into two groups.

Conversation structure. Four features describe the overall shape of a dialogue. *Conversation length*: total session duration in seconds. *Turn count*: number of participant turns. *Mean turn duration*: average length of a participant turn in seconds. *Words per turn*: average words per participant turn. Together, these indicate whether the dialogue consists of many short exchanges or fewer, longer stretches of speech.

Turn-taking dynamics. Three features capture how speakers manage transitions and share the floor. *Response latency*: the gap between the partner's last word and the participant's first word; only gaps within $[0, 10]$ s are retained. *Floor ratio*: the proportion of session time the participant is speaking. *Within-turn pause ratio*: the proportion of a participant's turn spent in silence (≥ 0.3 s gaps between words), reflecting online planning difficulty. Figure 2 illustrates how within-turn pauses are distinguished from between-turn gaps.

Session-level metrics (conversation length, turn count) were compared using paired t-tests ($n = 78$). Per-turn metrics use sessions with ≥ 8 participant turns, yielding unbalanced samples; these were analyzed using linear mixed-effects models with condition as a fixed effect and participant as a random intercept.

[1]Specifically, `gpt-realtime-2025-08-28`

[2]An anonymized repository containing the full LLM prompt is available at `https://osf.io/9kxsu/overview?view_only=ff7b5f764f1647a788c8541bc0b3fc31`.

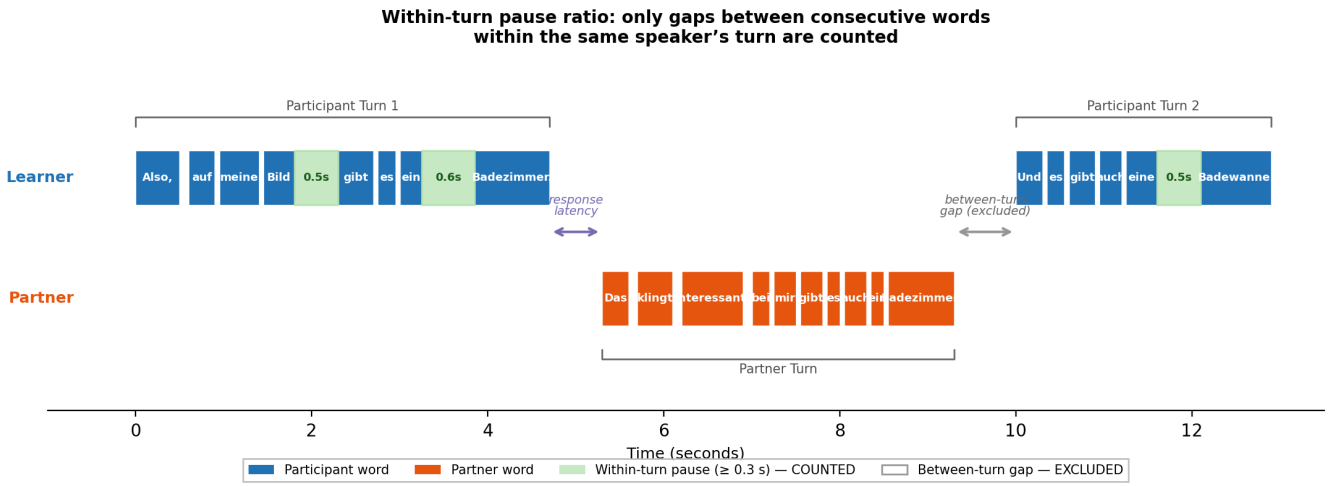

Figure 2: Illustration of temporal metrics extracted from word-level timestamps. Blue blocks are participant words; orange blocks are partner words. *Within-turn pause ratio* counts only gaps ≥ 0.3 s between consecutive words within the same speaker's turn (green). Gaps between speakers' turns (gray) are excluded from the pause ratio but are used to compute *response latency* (purple). Turn boundaries are reconstructed by grouping consecutive words from the same speaker.

4.2 Linguistic Uptake

Interactive alignment theory [28] predicts that interlocutors converge on shared linguistic representations during dialogue, from lexical choices to syntactic structures. We operationalize this as linguistic uptake: whether L2 learners adopt linguistic material from their interlocutor's speech. Figure 3 presents an illustration of how uptake is estimated. We measure uptake at two complementary levels:

Lexical uptake tracks whether learners adopt vocabulary items (lemmas) introduced by the partner, capturing breadth of vocabulary activation across the full session.
Syntactic uptake tracks whether learners reproduce morphosyntactic patterns (e.g., determiner–noun agreement, prepositional case government) from the partner's prior speech, capturing structural alignment within a dialogue.

Both measures impose a **first-use constraint**, such that each linguistic unit is scored only when it first appears in the learner's speech. This operationalization follows an input-mining paradigm in L2 research, where learners' later production is interpreted relative to prior independent production and intervening input [15]. In our design, the monologue preceding each dialogue provides a learner-specific baseline for lexical uptake, while syntactic uptake applies the same conservative first-use logic within dialogue by crediting templates only after prior partner use within a bounded recency window. We use uptake/mining to mean short-term reuse of available input, not acquisition; repeated task performance and the shared visual context may also contribute to some cases.

4.2.1 Lexical Uptake

The lexical uptake algorithm uses a **global timeline** approach, tracking each lemma across all four tasks in sequential order. The counterbalanced design creates two orderings:

- **Group 1** ($n = 46$): Monologue A/B → Human dialogue → Monologue C → AI dialogue
- **Group 2** ($n = 32$): Monologue C → AI dialogue → Monologue A/B → Human dialogue

The participant's first monologue establishes a **baseline vocabulary**. Words are tokenized, filtered (removing determiners, 49 pre-task vocabulary items, 153 English code-switching tokens, and words ≤ 2 characters), and lemmatized using spaCy's `de_core_news_sm` model. Words appearing on the Goethe-Institut A1 wordlist [26], approximately 714 high-frequency items, are also excluded as uninformative adoption candidates. A lemma counts as **adopted** if: (1) the interlocutor produced it before the participant, (2) it is not in the participant's baseline, and (3) it has not already been attributed to another source (**first-source-wins** rule). We use "adopted" rather than "learned" because we are measuring activation through interactive exposure, not acquisition.

Adoption is measured cumulatively without a recency window, consistent with accounts of lexical entrainment as a *historical* phenomenon in which interlocutors maintain partner-specific conceptual precedents beyond immediate adjacency [4], and with L2 alignment work that omits distance constraints under an interaction-as-learning framing [24]. Because the AI interlocutor produces substantially more speech than human partners, we report both raw adoption counts and adoption rates controlled for verbosity by dividing by the number of unique novel lemmas each interlocutor introduced beyond the participant's baseline (**pool size**). To test whether interaction type predicts adoption beyond input volume, we fit a mixed-effects regression with condition, pool size, and learner word count as fixed effects and participant as a random intercept.

4.2.2 Syntactic Uptake

Syntactic uptake measures whether learners reproduce morphosyntactic patterns from the interlocutor's speech **within**

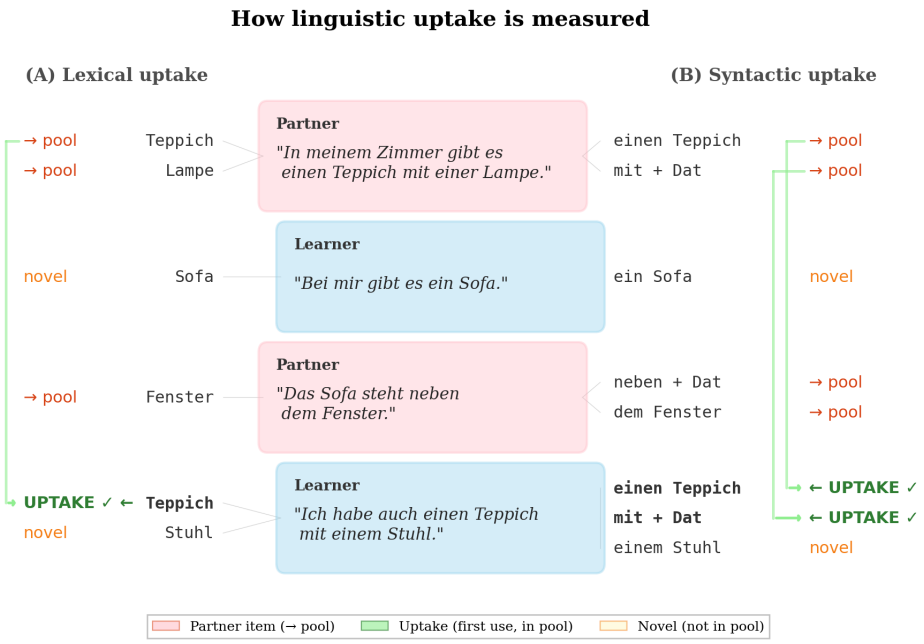

Figure 3: Illustration of linguistic uptake measurement at two levels, applied to the same example dialogue ($N_{\text{AI}} = 78$, $N_{\text{Human}} = 78$ in the full dataset). **(A)** Lexical uptake: content words used by the partner accumulate in a pool; when the learner first produces a matching word, it is counted as uptake. **(B)** Syntactic uptake: morphosyntactic templates—determiner–noun agreement (e.g., *einen Teppich*, masculine accusative) and preposition case government (e.g., *mit* + dative)—are tracked analogously. Green arrows trace each uptake event to its source in the partner's speech. Only the learner's first use of each item counts (first-use constraint); repeated uses are not double-counted. For syntactic templates, grammatical correctness is additionally validated against a noun-gender lexicon (e.g., *Teppich* → masculine).

Table 1: Target morphosyntactic patterns for syntactic uptake.

Pattern	Example	What it captures
DET-NOUN	*der Tisch* (Masc/Nom/Sg)	Det–noun gender/case/number agreement
ADP-CASE	*mit dem Hund* (mit → Dat)	Preposition case government
ADJ-NOUN	*großes Gemälde* (Neut/Nom/Sg)	Attributive adjective agreement
CONTRACTION	*im* (= *in* + *dem*, Dat)	Preposition–article fusion

a single dialogue. We extract four pattern types that constitute the core of German nominal morphology (see Table 1): determiner–noun agreement, prepositional case government, attributive adjective agreement, and preposition–article contractions. These are pervasive in the data ($M = 86$ learner-produced template instances per AI dialogue, 113 per human dialogue) and target well-documented areas of L2 German difficulty.

Extraction pipeline. Each turn is lightly preprocessed (removing filled pauses such as *äh* and *ähm*) and parsed with the Stanza German UD pipeline [31]. Each extracted template has an **anchored** representation that includes the noun lemma, surface form, and morphological features (e.g., DET_NOUN|*tisch*|*dem*|Masc|Dat|Sg), tying uptake to specific lexical items rather than abstract morphological categories.

Correctness checking. For DET-NOUN and ADJ-NOUN templates, we verify gender agreement against a lexicon of 91,270 German nouns. For ADP-CASE, correctness is checked for strict-case prepositions (e.g., *mit* → dative); two-way prepositions (e.g., *auf*, *in*), which can take dative or accusative case, are included in uptake matching but excluded from correctness analysis, as case selection depends on semantic context that cannot be determined from syntax alone. Contractions are inherently correct.

Uptake scoring. On the participant's first production of a template, we check whether it appeared in the source's prior speech. Unlike lexical adoption, syntactic uptake uses a recency window, reflecting the lag-sensitivity of structural priming documented in both L1 [14] and L2 task-based interaction [8], where prime–target contingency is typically coded within a bounded span [24]. Because AI turns are longer and syntactically denser than human turns, a fixed turn-count window captures unequal amounts of input across conditions. We therefore compare three window operationalizations: **turn-based** (last 3 source turns), **time-based** (last 15 seconds of source speech), and **template-count** (last 15 source

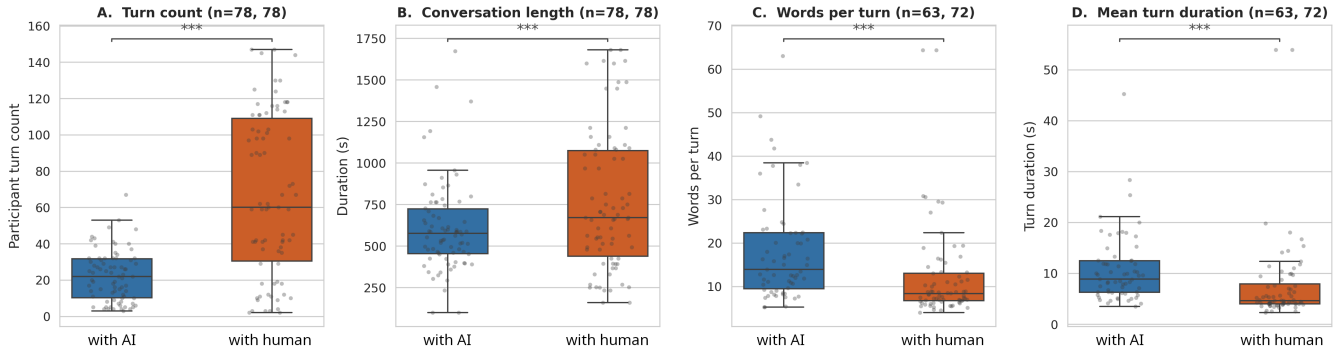

Figure 4: Conversation structure: AI vs. Human partner. (A) Participant turn count and (B) conversation length use all sessions ($n = 78$ per condition). (C) Words per turn and (D) mean turn duration use sessions with ≥ 8 participant turns ($n_{\text{AI}} = 63$, $n_{\text{Human}} = 72$). Box plots show median and interquartile range; individual sessions are overlaid as points. $^{***}p < .001$.

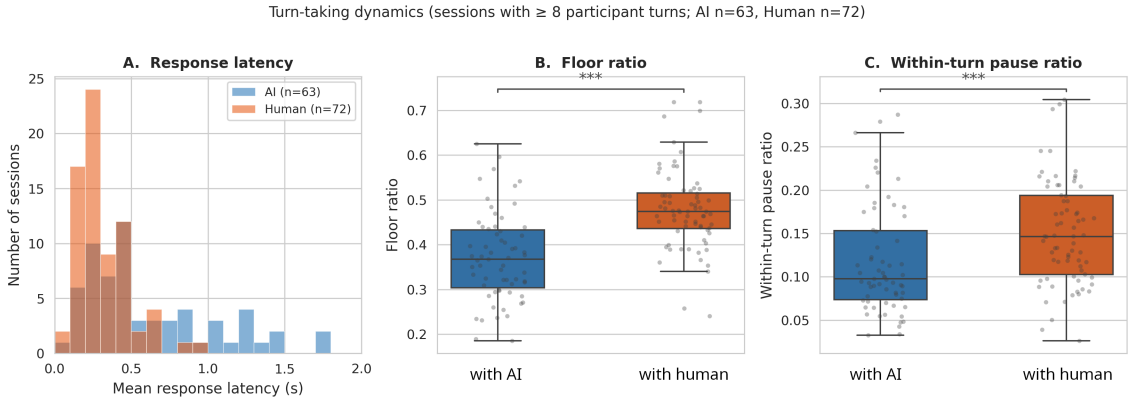

Figure 5: Turn-taking dynamics: AI vs. Human partner (sessions with ≥ 8 participant turns). (A) Overlapping histograms of mean response latency show clear separation between conditions. (B) Floor ratio: learners hold the floor for a smaller share of session time with the AI. The dashed line marks equal floor time (0.5). (C) Within-turn pause ratio: learners pause *less* within turns when speaking with the AI. $^{***}p < .001$.

templates, explicitly equalizing input volume). All results are tested via mixed-effects regression with condition, source pool size, and learner unique template count as fixed effects and participant as a random intercept.

The algorithm also detects **error–correction sequences**: the participant produces an incorrect form, the source subsequently models the correct form, and the participant later produces the corrected version.

5. RESULTS

We present results in three parts. Interactional dynamics (§4.1) characterize how dialogue structure and turn-taking differ between AI and human partners. Lexical and syntactic uptake (§4.2) examine whether and how learners adopt language from each interlocutor type. Survey results (§5.3) connect interaction behavior to learner attitudes and satisfaction.

5.1 Interactional Dynamics

We organize the findings into three domains: conversation structure, turn-taking dynamics, as well as consistency of results across four sites.

5.1.1 *Conversation Structure*

Human-human dialogues were significantly longer ($M = 764$ s vs. 608 s, $d = -0.44$, $p < .001$) and contained nearly three times as many turns ($M = 66.5$ vs. 22.2, $d = -1.35$, $p < .001$). Human partners engaged in rapid back-and-forth exchange, while AI dialogues were characterized by fewer, longer turns. With the AI, participants produced significantly longer turns ($M = 10.8$ s vs. 7.7 s, $d = 0.39$, $p < .001$) containing more words per turn ($M = 18.0$ vs. 12.1, $d = 0.51$, $p < .001$). Learners pack more content into each turn with the AI, but the threefold reduction in turn count means that total learner output is substantially lower than in human dialogue.

Figure 4 illustrates this trade-off: human dialogues produce many more turns (A), but learners produce more words per turn with the AI (C).

5.1.2 *Turn-Taking Dynamics*

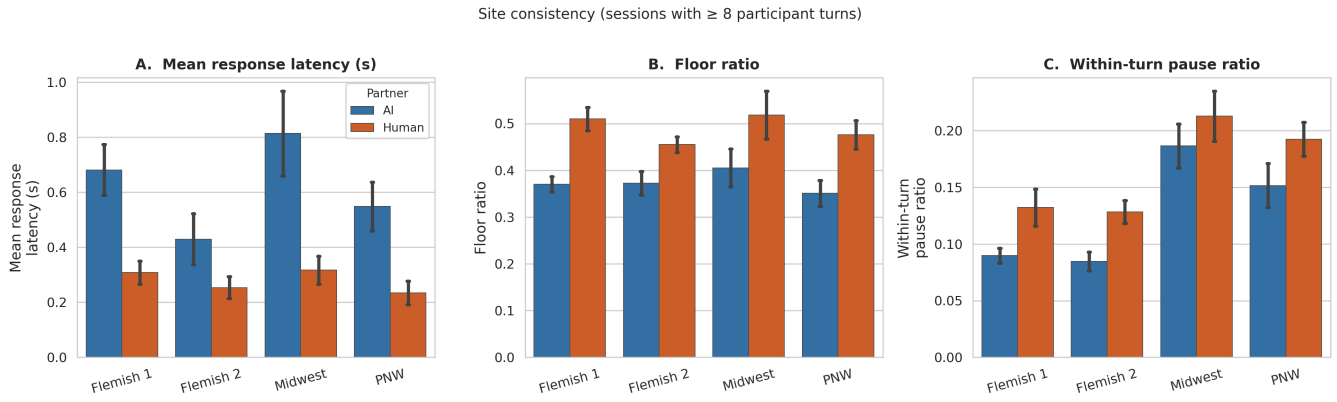

Figure 6: Site consistency: the three turn-taking metrics broken down by site and partner type (sessions with ≥ 8 turns). Error bars show ± 1 SE. At every site, response latency is higher with the AI, floor ratio is lower, and within-turn pause ratio is lower. No site reverses the direction of any effect.

Three interrelated measures reveal qualitatively different turn-taking patterns across conditions. Figure 5 visualizes the three turn-taking metrics, showing clear separation between conditions for response latency (A) and consistent differences in floor ratio (B) and within-turn pause ratio (C).

Participants took roughly twice as long to begin speaking after the AI ($M = 0.61$ s) as after a human partner ($M = 0.32$ s; $d = 0.90$, $p < .001$), indicating substantially longer response latencies in AI dialogue. Most human-partner latencies cluster below 0.3 s, while AI latencies spread between 0.2–1.0 s, likely reflecting the AI's longer, more information-dense turns.

Learners held the floor for a smaller proportion of session time when interacting with the AI ($M = 0.37$) than with a human partner ($M = 0.48$; $d = -1.14$, $p < .001$), representing one of the largest effects observed in the dataset. The AI's longer turns account for much of this difference, as they occupy a greater share of the conversational time.

Learners paused *less* within their own turns when speaking with the AI ($M = 0.12$ vs. 0.15; $d = -0.53$, $p < .001$), indicating greater within-turn fluency. When learners do hold the floor with the AI, they tend to speak more fluently within each turn.

Taken together, these measures show a consistent shift in interactional organization: AI dialogue features slower turn transitions and reduced learner floor time, but more fluent production when learners hold the floor.

5.1.3 *Site Consistency*

Figure 6 shows the contrasts were consistent in direction across all four sites. Response latency was higher with the AI at every site; floor ratio was lower; within-turn pause ratio was lower. The magnitudes varied—Midwest showed the largest response-latency difference, while Flemish 2 showed the smallest floor-ratio gap—but no site reversed the direction of any effect.

5.2 Linguistic Uptake

5.2.1 *Lexical Uptake*

The AI produced over twice as many novel lemmas as human partners (pool size: $M = 79.6$ vs. 36.4), yielding a higher descriptive adoption rate for human partners (16.2% vs. 9.3% of pool adopted). However, a mixed-effects regression controlling for pool size and learner word count found no significant condition effect ($\beta = -1.77$, $SE = 0.95$, $z = -1.87$, $p = .062$). Pool size ($\beta = 0.10$, $p < .001$) and learner word count ($\beta = 0.005$, $p < .001$) were the significant predictors: after accounting for input volume and learner output, condition does not reliably predict adoption.

To disentangle partner type from task order, we compared adoption at the same sequential position. Table 2 presents the results of this analysis. In position 2—where the depleted vocabulary pool provides a more sensitive test—AI participants adopted significantly more words ($M = 4.6$ vs. 2.6; $d = 0.72$, $p = .003$). In position 1, the direction is consistent but nonsignificant ($d = 0.42$, $p = .079$).

5.2.2 *Syntactic Uptake*

A total of 156 participant-level dialogue records were analyzed: 78 AI dialogue records, and 78 human-partner records derived from 39 human-human conversations. The results are summarized in Table 3. Learners' cumulative uptake rate was higher with the AI ($M = .16$, $SD = .11$) than with human partners ($M = .08$, $SD = .06$; $d = 0.93$), but as with lexical adoption, the AI also provided a substantially larger source pool ($M = 155$ vs. 90 unique templates; $d = 1.35$). After controlling for pool size and learner unique template count, cumulative uptake showed a positive but nonsignificant trend ($\beta = 1.55$, $SE = 0.92$, $z = 1.69$, $p = .090$). Recency-windowed uptake told a different story: the AI advantage was significant across all three operationalizations—turn-based ($\beta = 3.18$, $p < .001$), time-based ($\beta = 3.04$, $p < .001$), and template-count ($\beta = 2.84$, $p = .001$)—including the window that explicitly equalizes input volume. This confirms that the AI's short-term priming advantage reflects genuine structural priming, not merely a larger input pool.

Correctness rates were comparable: AI $M = .82$ ($SD = .13$)

Table 2: Lexical adoption by sequential position and partner type. Group 1 ($n = 46$) had the human partner first; Group 2 ($n = 32$) had the AI first. Position-matched comparisons use between-subjects Welch's t-tests.

Position	Partner type	n	M	SD	t	p	d
First dialogue	Human (Group 1)	46	8.6	5.5	1.79	.079	0.42
	AI (Group 2)	32	11.2	6.8			
Second dialogue	Human (Group 2)	32	2.6	2.8	3.12	.003**	0.72
	AI (Group 1)	46	4.6	2.8			

Table 3: Syntactic uptake by condition. Descriptive statistics (Welch's t-tests) and mixed-effects regression results (β = condition coefficient, AI = 1; models control for source pool size and learner unique templates with participant random intercept).

Measure	**AI** M (SD)	**Human** M (SD)	t	d	β	SE	z	p
Cumulative uptake (rate)	.16 (.11)	.08 (.06)	5.84	0.93	—	—	—	—
Cumulative uptake (count)	7.3 (5.6)	5.4 (4.6)	2.28	0.36	1.55	0.92	1.69	.090

Recency: 15 templates (count)	5.2 (5.3)	3.2 (2.8)	3.00	0.48	2.84	0.87	3.27	.001**

Table 4: Key baseline attitudes: AI vs. Human peers (N=55). All items rated on a 5-point Likert scale (1 = Strongly Disagree, 5 = Strongly Agree).

Item	M	SD
Practicing speaking is valuable	4.56	0.69
AI effectiveness	3.22	0.76
AI enjoyment	2.73	0.89
Relaxation: AI	3.25	1.02
Relaxation: Proficient speakers	2.82	1.19
Access to proficient speakers	2.67	1.11

vs. Human $M = .80$ ($SD = .13$); $p = .316$, $d = 0.16$. Higher uptake with the AI does not come at the cost of morphological accuracy. Correction sequences were numerically more frequent with human partners (total: 38 vs. 27), but per-participant rates did not differ significantly ($M = 0.49$ vs. 0.35; $p = .215$).

5.3 Survey Analysis

Of the 78 participants, 55 completed matched pre- and post-surveys; 52 had complete data for the directional sentiment composite used in the paired t-test below. These data allow us to assess how learner attitudes toward AI shift after direct experience and whether behavioral features of the interaction predict satisfaction.

Baseline attitudes. Participants entered with predominantly skeptical attitudes toward AI: 60% described themselves as skeptical or unsure, and only 14.5% as enthusiastic adopters. AI-specific Likert items scored near or below neutral (perceived effectiveness $M = 3.22$, enjoyment $M = 2.73$), while general speaking practice was highly valued ($M = 4.56$). Notably, relaxation with AI ($M = 3.25$) already exceeded relaxation with proficient speakers ($M = 2.82$), and the lowest-scoring item, having enough opportunities to speak with proficient speakers ($M = 2.67$), points to a perceived access gap (see Table 4).

Post-experience shift. Attitudes improved significantly after the study: a paired t-test on directional sentiment scores showed a mean increase of +0.48 ($t(51) = -4.58$, $p < .0001$, $d = 0.64$), with 75% of participants becoming more positive. Post-study, 67.3% liked the AI interaction, 81.8% agreed AI can be useful for L2 speaking practice, and 34.5% reported learning new vocabulary.

Behavioral predictors of satisfaction. To connect attitudinal outcomes to interaction behavior, we fit OLS regressions predicting post-satisfaction and attitude change from behavioral features of the AI dialogue. Table 5 presents the results of survey regressions, fit using ordinary least squares (`statsmodels`; [34]) with site as a categorical covariate.

Pre-study attitude predicted post-satisfaction ($\beta = 0.36$, $p = .006$), but the strongest behavioral predictor was within-turn pause ratio ($\beta = -4.78$, $p = .008$): learners who paused more during AI turns, reflecting greater online planning difficulty, reported lower satisfaction and smaller attitude gains ($\beta = -5.91$, $p = .006$). Floor ratio was not significant, suggesting that *how fluently* learners spoke mattered more than *how much* they spoke. Neither lexical adoption rate nor syntactic uptake rate predicted satisfaction ($p > .45$), indicating that the subjective experience of AI interaction is shaped by production fluency rather than by receptive alignment.

6. DISCUSSION

The fluency, uptake, and survey results converge on one conclusion: AI and human dialogue create distinct but complementary conditions for L2 practice.

Monologue-in-dialogue. AI dialogue structurally approximates supported monologue. Learners produce sustained output with fewer, longer turns, slower responses, and less floor competition, while producing more fluent speech within each turn. The AI's patient, non-competitive style shifts learners from reactive turn management to more deliberate, content-focused production. Human dialogue, by contrast, is rapid and interactive: frequent turns, fast responses, balanced floor time, and more within-turn hesitation. The interactional work of peer conversation (collaborative reference-building, repair negotiation, and affiliative floor manage-

ment) is largely absent from AI dialogue. This is not a failure of the AI to "be human" but a description of what the interaction actually is.

What the AI scaffolds. The AI's verbose, syntactically regular speech, in this specific model-prompt-task configuration, creates favorable conditions for short-term structural alignment. Overall, AI dialogue exposes learners to more input and elicits more uptake in absolute terms. The deeper finding is that the AI's syntactic priming advantage survives all controls for input volume, pointing to a qualitative difference: complete, well-formed constructions without the fragments and restarts of peer speech yield cleaner targets for short-term reuse. At the lexical level, the AI provides greater exposure but not more efficient uptake per unit of input ($p = .062$ after controls). The AI's distinctive pedagogical contribution is thus specifically structural. This is particularly notable given that meaning-focused tasks like spot-the-difference typically direct learner attention toward vocabulary rather than grammar [13]; the syntactic priming observed here operates implicitly, suggesting a potential affordance of AI interaction worth investigating in future work.

What human partners scaffold. Human dialogue exercises a different set of capacities. The rapid turn exchange, floor competition, and negotiation sequences characteristic of peer interaction create conditions for developing interactional competence, skills not exercised in AI dialogue. The information-gap task produces its richest interactional outcomes with a partner who *cannot* resolve gaps efficiently. Whether human dialogue also promotes more durable lexical learning through interactional grounding remains a question our data suggest but cannot confirm.

Learner experience. Attitudes toward AI improved significantly after the task, but satisfaction was predicted by within-turn production fluency, not by uptake. Learners who paused more within their turns reported lower satisfaction, suggesting that the subjective quality of AI interaction hinges on whether the learner can produce fluent speech in the space the AI provides, not on how much language they absorb from the AI's input.

7. CONCLUSIONS

AI and human dialogue scaffold L2 production through complementary mechanisms: structural priming through regular input in one case, interactional competence through coordinative demand in the other. The design challenge is not to make AI dialogue more like human dialogue, but to exploit what each mode does well.

This points to concrete principles for integrating voice-based AI into language curricula: For curricula, this suggests four design principles. First, AI tasks are well suited to focused morphosyntactic practice, where regular input can support priming of constructions such as dative prepositions and gender agreement. Second, AI practice should complement rather than replace peer speaking, since human dialogue exercises turn competition, clarification requests, repair, and collaborative floor management. Third, AI verbosity should be calibrated: shorter, less complete AI turns may reduce floor dominance and create more space for learner-initiated language. Finally, uptake metrics can support adaptive feedback on vocabulary and constructions adopted, missed, or produced incorrectly from ASR transcripts.

Limitations. Several limitations apply. Uptake measures cannot fully separate priming from parallel activation driven by shared task context; causal claims require manipulating interlocutor language. NLP pipelines trained on Standard German may degrade on disfluent L2 speech; word-level ASR errors were not corrected, although German-speaking authors verified speaker labels, task boundaries, and broad coherence. First-use counting captures breadth rather than depth of uptake, and the lexical first-source-wins rule creates a task-order confound ($d = 1.71$), addressed with lower-powered position-matched comparisons. The study cannot determine whether short-term priming becomes durable learning; delayed post-tests are needed. Transcript-based analysis also excludes prosody, pronunciation, stress, intonation, and segmental accuracy. The comparison involved stimulus and modality asymmetries: human partners viewed images directly and interacted face-to-face or by Zoom, whereas the AI received English text descriptions and interacted through audio only. Some temporal effects may therefore partly reflect interface latency, VAD behavior, and visual coordination cues rather than interlocutor type alone. Finally, the AI condition reflects one system configuration (model, voice, prompt, VAD setting, and task interface) with university German learners, mostly Dutch- or English-dominant, performing one task type; future work should replicate across AI systems, L1 backgrounds, proficiency levels, target languages, and tasks.

Acknowledgments

We would like to thank all of the professors, teachers and students who worked with great dedication to plan for, collect and process all of the data for these experiments.

ABSTRACT

Classroom discourse among multilingual learners (MLLs) routinely integrates cognitive, interpersonal, and organizational work, yet scalable discourse analytics in educational data mining (EDM) rely on linguistic features whose relationship to these meanings is often unclear. This study examines how psycholinguistic features derived from Linguistic Inquiry and Word Count (LIWC) correspond to expert interpretations of meaning in multilingual small-group science discourse. Grounded in Systemic Functional Linguistics (SFL), we analyze associations between LIWC categories and human annotations of the ideational and interpersonal metafunctions across ten classroom transcripts. Using three complementary analyses, we evaluate empirical alignment patterns and theory-driven predictions. Results show that LIWC features align most consistently with interpersonal meaning, capturing stance and social positioning, whereas ideational meaning is reflected more selectively in measures of elaboration and in references to participants and actions. These findings clarify what dimensions of classroom meaning are accessible as LIWC-based representations and highlight important limitations of psycholinguistic features for modeling learning-relevant discourse in multilingual settings.

Educational Data Mining, Collaborative Learning, Multilingual Discourse, Systemic Functional Linguistics, Interpretability

1. INTRODUCTION

Classroom discourse plays a central role in collaborative learning by shaping how multilingual learners (MLLs) construct ideas, negotiate understanding, and coordinate participation during instruction. In multilingual classrooms, these processes are often realized through translanguaging practices in which learners flexibly draw on multiple linguistic resources to foster joint sense-making and participation [2, 16]. Prior research shows that student talk in small-group STEM activities routinely serves multiple communicative functions simultaneously, such as combining problem solving, interpersonal positioning, and discourse organization within a single spoken utterance [20, 5, 16].

Educational data mining (EDM) has increasingly turned to discourse analysis to study classroom interaction and learning processes at scale [25, 6]. This approach offers powerful tools for characterizing multilingual meaning-making and collaborative processes across large datasets. However, many commonly used linguistic representations rely on surface-level features whose relationship to learning-relevant discourse functions remains underspecified, particularly in multilingual settings where it does not conform to monolingual or standardized norms [3, 12]. For instance, a student might say, "No sé... [I don't know] but I think it's because it evaporates faster," where the phrase may register pronoun use, negation, or cognitive markers in surface feature models, while simultaneously contributing to collaborative hypothesis building that may not be fully represented.

Linguistic Inquiry and Word Count (LIWC) provides one widely adopted and interpretable approach to discourse analysis by quantifying psycholinguistic dimensions such as cognitive processing, affective tone, and social orientation [27, 22]. LIWC features have been used extensively in educational research to examine student engagement, performance, and experience, including in STEM learning contexts [23, 17]. Despite its widespread use, LIWC is often applied without an explicit theory of discourse and assumes monolingualism, leaving open questions about what kinds of communicative work these features actually reflect in linguistically diverse classroom interactions. In addition, MLLs routinely draw on multiple languages for both conceptual sense-making and social interaction, even when English is the official medium of instruction [8, 21]. Approaches that rely on language-specific dictionaries risk under-representing how meaning is distributed across languages, with implications for how discourse is interpreted and used in downstream models of learning.

Kaycie Barron, Ananya Ganesh, Shamya Karumbaiah, and Mariana Castro. What Do LIWC Features Capture in Multilingual Classroom Talk? A Systemic Functional Linguistic Analysis. This study addresses this gap by examining how LIWC features align with human interpretations of discourse in K-12 multilingual science classrooms. Drawing on Systemic Functional Linguistics (SFL), which theorizes how meaning is realized through language across the ideational, interpersonal, and textual metafunctions [10, 19], we analyze the correspondence between select LIWC variables and expert-annotated metafunctions in small-group science discussions. Rather than treating linguistic features as predictors of downstream outcomes, we adopt a theory-informed analytic approach to estimate how LIWC's psycholinguistic variables represent different dimensions of meaning-making.

1.1 Multilingual Classroom Discourse

Research on classroom discourse has long emphasized that knowledge construction is achieved through interactional processes (i.e., explanation, questioning, critique, and uptake) instead of isolated individual contributions [20, 5]. In multilingual classrooms, these interactions are frequently characterized by translanguaging practices in which students coordinate meaning across and beyond languages and registers [7, 9]. Studies of multilingual STEM classrooms show that student contributions often integrate cognitive work, social alignment, and discourse organization within a single turn, reflecting the inherently multifunctional nature of collaborative sense-making [16].

While discourse analysis approaches have documented these patterns in detail, they typically rely on labor-intensive qualitative methods and small datasets, limiting their scalability for EDM applications [16]. This tension motivates the need for computational representations that remain sensitive to the functional complexity of classroom talk.

1.2 LIWC

LIWC is one of the most widely used dictionary-based tools for analyzing psychological, cognitive, and social dimensions of language. It operationalizes linguistic features as proportions of words associated with categories such as cognitive processes, affect, social relationships, and function words, as well as composite summary measures including Analytical Thinking, Clout, Authenticity, and Emotional Tone [27, 22].

In educational research, LIWC has been used to study how linguistic patterns relate to student outcomes and experience. For example, Lin, Yu, and Dowell [17] showed that cognitive and social LIWC features were differentially associated with performance and sense of belonging in online STEM courses. Other work by [23] showed through LIWC analysis that students' use of function words and analytic language patterns in their writing predicts academic performance.

Foundational LIWC research cautions that psycholinguistic categories do not map transparently onto communicative functions. The interpretation of any given LIWC feature depends on context, genre, and interactional setting, requiring theoretical grounding [27]. In multilingual classroom discourse, this limitation is compounded by LIWC's reliance on language-specific dictionaries. As MLLs fluidly integrate linguistic resources, analysis must either restrict data to one language or transform translanguaged discourse into monolingual representations. Both approaches risk distorting how meaning is distributed across languages and interaction, particularly in collaborative settings where ideational and interpersonal work are tightly integrated.

1.3 Systemic Functional Linguistics

SFL provides a principled framework for interpreting discourse by distinguishing among ideational and interpersonal metafunctions, which capture how speakers construe experience and negotiate social relations during interaction [19]. These dimensions have been widely used to analyze classroom talk and multilingual academic language practices, particularly in studies of collaborative learning and sense-making [26, 28].

- **Ideational**: construing experience, representing processes or phenomena, and elaborating content.
- **Interpersonal**: expressing stance, evaluation, uncertainty, and social alignment with others.

SFL also theorizes a *textual* metafunction concerned with cohesion, information flow, and discourse organization across extended stretches of discourse. However, textual meaning is primarily realized across turns and interactional sequences instead of isolated speaker turns. Because LIWC operates at the level of short utterances and relies on surface lexical and punctuation cues, it is poorly suited for capturing textual resources that develop thematically in dialogic classroom interaction. Accordingly, while textual meaning was annotated to characterize the multifunctional nature of classroom discourse, subsequent LIWC analyses in this study focus exclusively on ideational and interpersonal metafunctions.

2. METHODS

2.1 Dataset

The dataset consists of 204 utterances drawn from ten small-group science classroom transcripts collected across three Midwestern K–12 school districts. Transcripts were selected from longer classroom sessions as part of a broader study of multilingual interaction in science classrooms in Fall 2024 and Spring 2025. For the present analysis, we focus on pre-selected segments capturing focal episodes of collaborative sense-making and translanguaging.

Across these segments, 123 students participated. Classrooms varied in science content and linguistic demographics (four 6th-grade science classrooms, one 9th-grade biology classroom, and one 10th-grade chemistry classroom), and included MLLs with diverse language backgrounds (e.g., Spanish, Arabic) as well as monolingual English-speaking peers. The selected segments represent authentic small-group problem-solving interactions in which students collaboratively interpreted evidence, negotiated understanding, and coordinated action using their multilingual resources.

The data used in this study were collected as part of a broader research project approved by the Institutional Review Board (IRB) (ID: 2024-1029-CP004) at the University of Wisconsin-Madison. Informed consent was obtained from parents/guardians and assent from students in English and Spanish. All data were de-identified before analysis.

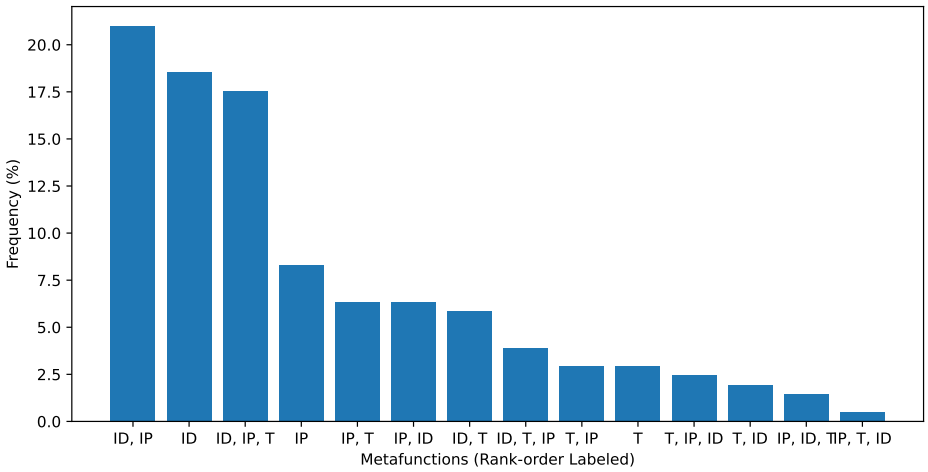

Figure 1: Distribution of adjudicated SFL metafunction labels. ID = ideational; IP = interpersonal; T = textual.

2.2 SFL Annotation

Two bilingual annotators fluent in English and Spanish independently annotated all utterances using a finalized annotation protocol grounded in SFL. Both annotators had expertise in qualitative analysis of multilingual classroom discourse. Annotations served as the reference standard for examining how psycholinguistic features align with functional meanings in multilingual student talk. Disagreements were resolved through structured discussion, with annotators jointly revisiting interpretations and reaching consensus iteratively [15].

Each utterance was labeled for the presence of one or more SFL metafunctions to reflect the multifunctional nature of classroom discourse. Annotators were permitted to assign multiple labels to a single utterance when meanings overlapped, consistent with prior discourse-analytic research on multilingual STEM classrooms. Table 1 provides an illustrative excerpt showing how ideational, interpersonal, and textual meanings can co-occur across short stretches of multilingual peer interaction.

Unit of analysis. The unit of analysis was a single speaker turn, defined as one sentence or short utterance. Utterances are understood as socially and interactionally situated units of meaning-making [1]. Multi-clause turns were annotated as a whole when they reflected a unified communicative intent.

Rank-order labeling. When multiple metafunctions were present, annotators assigned all relevant labels and ranked them by prominence, with the primary communicative function listed first. For example, the utterance *¿Qué pasó? ¿Qué vieron? [What happened? What did you see?]* was labeled as primarily ideational, reflecting the solicitation of experiential information, and secondarily interpersonal, reflecting engagement with peers and the initiation of joint sense-making. Annotators relied on expert judgment rather than fine-grained grammatical segmentation.

Annotations revealed substantial multifunctionality across the corpus. As shown in Figure 1, utterances expressing more than one metafunction were more common than single-function realizations, with ideational–interpersonal combinations occurring most frequently, followed by singular ideational turns and three-way metafunctional combinations. Purely interpersonal or purely textual utterances were comparatively rare.

2.3 Label Reliability

Inter-rater reliability was assessed using Cohen's kappa for each metafunction annotation, as seen in Table 2. Agreement was substantial for ideational meaning ($\kappa = 0.551$), high for interpersonal meaning ($\kappa = 0.693$), and moderate for textual meaning ($\kappa = 0.444$), following conventional interpretation thresholds [14]. Overall micro-averaged agreement was $\kappa = 0.595$, with an exact set-level agreement of 0.620. All disagreements were adjudicated by the primary author to produce a single gold-standard label set used in subsequent analyses.

2.4 LIWC Feature Extraction

Each utterance was analyzed using LIWC-22. LIWC produces a broad set of variables capturing summary dimensions, psychological processes, affective and social language, and function word use. Most variables are calculated as proportions of total words, while summary variables are standardized composite scores derived from underlying categories [27]. The psychometric foundations of LIWC-22 are documented in the LIWC-22 manual [4], and the English LIWC-22 and Spanish ES-LIWC2007 variables in this study are listed in the Appendix.

Because the unit of analysis is a short speaker turn, many LIWC variables were sparse or zero-inflated at the utterance level. To reduce noise associated with short texts and enable

Table 1: Excerpt of multilingual small-group science discourse with SFL metafunction labels.

Speaker	Utterance	Meta-functions
Yesenia	¿Qué pasó? ¿Qué vieron? *[What happened? What did you see?]*	Ideational, Interpersonal
Trevor	Las personas de … o los científicos … *[The people … or the scientists …]*	Ideational
Yesenia	Ajá, ¿qué están haciendo los científicos? *[Uh-huh, what are the scientists doing?]*	Ideational
Trevor	Matando a las … um … urchins *[Killing the … um … urchins]*	Ideational, Interpersonal
Yesenia	¿Erizos? *[Urchins?]*	Ideational, Interpersonal
Trevor	Erizos, yeah *[Urchins, yeah]*	Ideational
Yesenia	¿Están matando a los erizos porque qué pasó con los erizos? *[Are they killing the urchins because what happened with the urchins?]*	Ideational, Textual
Trevor	Se comen la kelpo *[They eat the kelp.]*	Ideational
Yesenia	Entonces, ¿hay muchos erizos o pocos erizos? *[So, are there many urchins or few urchins?]*	Ideational
Alonso	Muchos *[Many.]*	Ideational, Textual

Table 2: Human–human agreement for metafunction labels per utterance.

Metafunction	κ

interpretable comparison across features, LIWC variables appearing in fewer than 5% of utterances were excluded from analysis. The remaining variables were then carried forward to the correlation analyses described below, where 52 exceeded the median absolute correlation threshold for at least one metafunction and were retained for reporting.

2.5 Statistical Analysis

To examine how LIWC features correlate with functional discourse, we conducted three complementary analyses. Together, these analyses examine empirical patterns, theory-driven expectations, and robustness across language conditions.

Analysis 1: Empirical alignment between LIWC features and SFL metafunctions. First, we examined associations between LIWC variables and adjudicated SFL metafunction labels using correlation analysis. The ideational and interpersonal metafunctions were represented as binary indicators indicating whether they were present in a given utterance, which allowed both metafunctions to co-occur within the same turn.

Spearman rank-order correlations were computed between each LIWC variable and each metafunction indicator. Spearman correlation was selected to accommodate non-normally distributed variables and the ordinal nature of feature ranks. Given the exploratory goal of identifying interpretable alignment patterns, we focused subsequent analyses on LIWC variables whose correlations exceeded the median absolute correlation value for each metafunction. This thresholding strategy was used to distinguish features showing relatively stronger alignment with expert annotations from those exhibiting weak or inconsistent associations, without assuming statistical significance in a small corpus. Correlation results were visualized using heatmaps to facilitate comparison across metafunctions and LIWC feature groups.

Analysis 2: Theory-driven alignment with SFL lexicogrammatical resources. As a second line of analysis, we adopt a theory-driven approach to evaluate whether psycholinguistic features derived from LIWC align with lexicogrammatical resources theorized in SFL. Whereas Analysis 1 examined empirical associations between LIWC variables and annotated metafunctions, Analysis 2 tests whether LIWC variables hypothesized to index ideational or interpersonal meaning *a priori* exhibit differentiated alignment with these metafunctions in the annotated transcript.

Based on SFL discourse semantics and genre theory [18, 11], we specified LIWC variables expected to align with ideational and interpersonal meaning, respectively (see the Appendix). Variables were selected as surface linguistic indicators plausibly associated with different meaning orientations: ideational predictors index elaboration and references to processes or phenomena (e.g., *WC*, *WPS*, *Perception*, *space*, *differ*); interpersonal predictors index stance, social positioning, and participant orientation (e.g., *ppron*, *you*, *Social*, *Clout*). Spearman correlations were computed between each LIWC variable and metafunction.

Analysis 3: Language and Dictionary-Based Error Analysis. As a third analysis, we examined the robustness of LIWC–SFL alignment across language conditions while accounting for constraints of LIWC dictionary design. Currently, LIWC-22 supports analysis using only one language-specific dictionary at a time[1]. Accordingly, we conducted two parallel analyses across all three transcript conditions: (a) original translanguaged utterances, (b) English-only versions, and (c) Spanish-only versions using the LIWC-22 English dictionary and the internal ES-LIWC2007 Spanish dictionary.

Within each dictionary, LIWC features were computed sep-

[1]We confirmed this constraint with the creators of LIWC-22.

arately for all transcript conditions and related to the same expert-annotated SFL metafunction labels. Following prior LIWC cross-language methodology, analyses focused on within-dictionary patterns and not on direct comparisons across languages [24]. Although the English and Spanish LIWC dictionaries share category structures, subtle differences in linguistic realization and coverage exist (e.g., subject pronoun omission in Spanish), motivating a within-language analytic approach.

Together, the three analyses serve complementary purposes. Analysis 1 establishes empirical alignment patterns between LIWC features and expert interpretations of meaning. Analysis 2 evaluates whether these patterns align with theory-driven expectations about how meaning is realized lexicogrammatically. Analysis 3 probes the stability of these alignments under common preprocessing and language-restriction decisions in EDM. This design supports both exploratory and theory-driven analysis.

3. RESULTS

3.1 Analysis 1: LIWC Predictors and SFL Metafunctions

We examined associations between LIWC variables and expert-annotated SFL metafunctions using Spearman rank-order correlations. Ideational and interpersonal metafunctions were represented as binary indicators denoting whether each meaning was present in a given utterance. Fifty-two LIWC variables exceeded the median correlation threshold for at least one metafunction and were retained for analysis. For interpretability, variables were grouped post hoc into six LIWC-informed categories. Separate heatmaps were generated for each category to visualize alignment patterns with ideational and interpersonal meanings.

3.1.1 Summary Variables

Figure 4 presents correlations between SFL metafunctions and LIWC summary variables. Ideational meaning showed the strongest alignment within this category, with positive correlations for word count (WC; $\rho = 0.28$), words per sentence (WPS; $\rho = 0.28$), and BigWords ($\rho = 0.22$). Clout was also positively associated with ideational meaning ($\rho = 0.16$), while dictionary coverage (Dic) showed a negative association ($\rho = -0.18$).

Interpersonal meaning exhibited weaker and more selective alignment with summary variables. Clout showed a positive correlation ($\rho = 0.19$), while Analytic was negatively associated ($\rho = -0.23$). Other summary variables showed correlations close to zero.

3.1.2 Linguistic Dimensions

Figure 2 shows correlations for LIWC linguistic dimension variables. Interpersonal meaning exhibited the clearest alignment in this category, with the strongest associations observed for personal pronouns (ppron; $\rho = 0.28$), pronouns overall ($\rho = 0.21$), first-person singular *I* ($\rho = 0.20$), and second-person *you* ($\rho = 0.16$).

Ideational meaning showed more moderate and distributed associations across linguistic dimensions, including positive correlations for ipron ($\rho = 0.17$), determiners ($\rho = 0.17$), prepositions ($\rho = 0.17$), auxiliary verbs ($\rho = 0.15$), and conjunctions ($\rho = 0.14$). The aggregate Linguistic category was negatively associated with ideational meaning ($\rho = -0.23$).

3.1.3 Psychological Processes

Figure 3 presents correlations between metafunctions and LIWC psychological process variables. Ideational meaning showed its strongest association with *differ* ($\rho = 0.18$), followed by affiliation ($\rho = 0.11$) and cause-related language ($\rho = 0.08$). Other cognitive process categories showed weak or near-zero associations.

Interpersonal meaning exhibited modest positive correlations for discrepant language (*discrep*; $\rho = 0.12$), cognition ($\rho = 0.10$), and cognitive processing more broadly ($\rho = 0.09$), while *differ* showed a small negative association ($\rho = -0.06$).

3.1.4 Affect and Social Processes

Figure 5 shows correlations for LIWC affective and social process variables. Interpersonal meaning aligned most clearly with this category, with positive correlations for Social ($\rho = 0.22$), socrefs ($\rho = 0.18$), socbehav ($\rho = 0.12$), and assent ($\rho = 0.15$).

Ideational meaning showed weak associations with most affective and social variables, with the exception of a strong negative correlation with assent ($\rho = -0.35$), indicating that brief agreement tokens were unlikely to be annotated as ideational.

3.1.5 Perception and Time Orientation

Figure 6 presents correlations for LIWC perception and time orientation variables. Ideational meaning showed consistent positive alignment with perception ($\rho = 0.22$), spatial language ($\rho = 0.19$), motion ($\rho = 0.13$), and temporal focus, including past ($\rho = 0.12$) and future ($\rho = 0.12$) orientation.

Interpersonal meaning showed weak associations across this category, with correlations near zero for most variables and small positive correlations for present ($\rho = 0.08$) and future focus ($\rho = 0.05$).

3.1.6 Conversational and Punctuation Features

Figure 7 shows correlations for LIWC conversational and punctuation variables. Ideational meaning exhibited consistent negative correlations with conversational markers, including Conversation ($\rho = -0.29$), nonfluencies ($\rho = -0.18$), overall punctuation density (AllPunc; $\rho = -0.16$), and comma use ($\rho = -0.13$). In contrast, Apostro ($\rho = 0.12$) and OtherP ($\rho = 0.11$) showed small positive associations.

Interpersonal meaning showed weak and inconsistent alignment across conversational and punctuation features, with correlations ranging from $\rho = -0.03$ to 0.10.

3.2 Analysis 2: LIWC Alignment with SFL Lexicogrammatical Resources

We examined whether LIWC variables predicted *a priori* to align with ideational or interpersonal lexicogram-

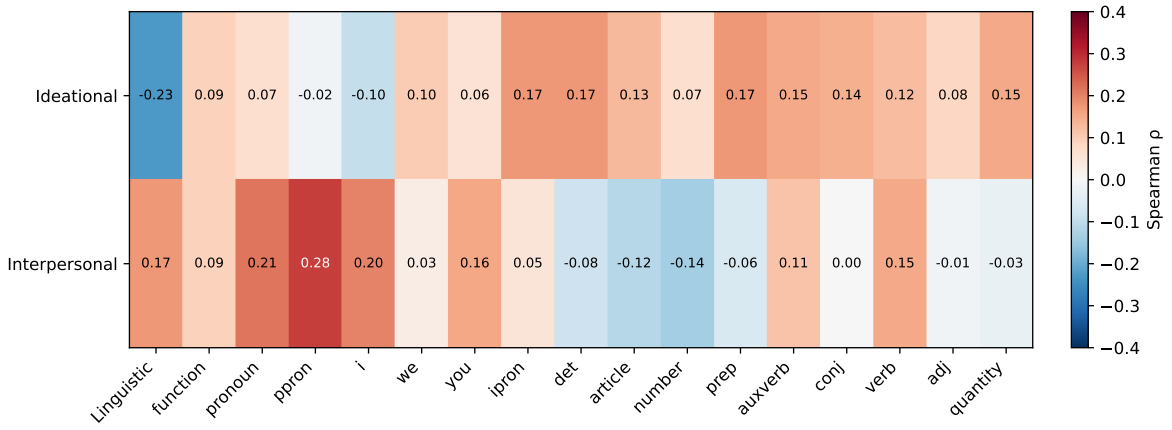

Figure 2: Spearman correlations between SFL metafunctions and LIWC Linguistic Dimensions.

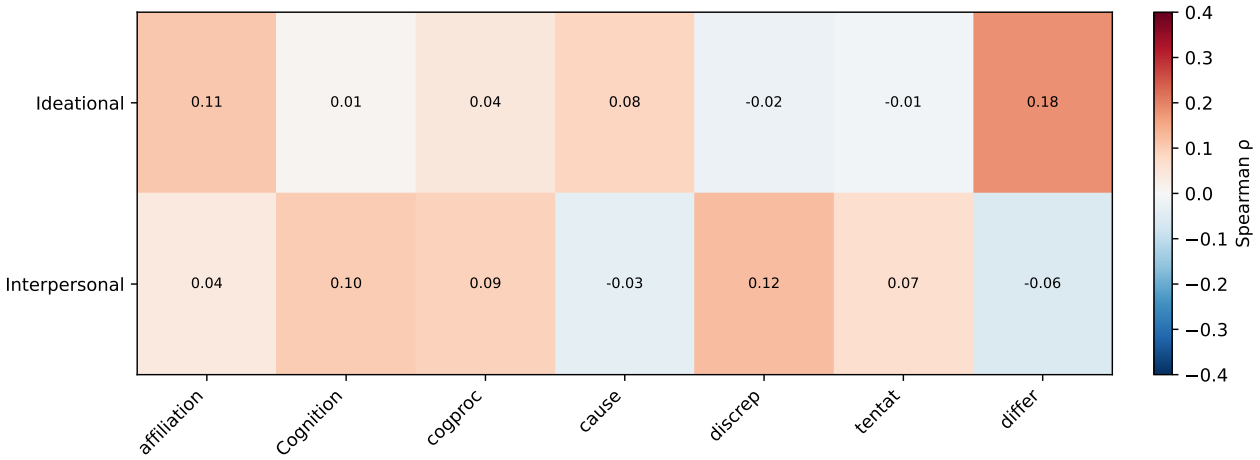

Figure 3: Spearman correlations between SFL metafunctions and LIWC Psychological Processes.

matical resources exhibit empirical alignment with expert-annotated metafunctions. For each theoretically-specified LIWC variable, Spearman correlations were computed with both ideational and interpersonal indicators to give direct comparison across metafunctions.

Ideational-predicted LIWC variables. Figure 8 shows Spearman correlations for LIWC variables hypothesized to index ideational meaning, displayed for both ideational and interpersonal metafunctions. Measures of elaboration showed the strongest positive correlations with ideational meaning, including word count (WC; $\rho = 0.28$) and words per sentence (WPS; $\rho = 0.28$). Perceptual and experiential variables also showed positive correlations with ideational meaning, including *Perception* ($\rho = 0.22$), *space* ($\rho = 0.19$), *motion* ($\rho = 0.13$), and *differ* ($\rho = 0.18$).

Across these variables, correlations with interpersonal meaning were weaker or near zero. LIWC cognitive process variables (e.g., *cogproc*, *cause*, *insight*, *discrep*) showed weak or inconsistent correlations with ideational meaning (all $\rho < 0.10$).

Interpersonal-predicted LIWC variables. Figure 9 presents correlations for LIWC variables hypothesized to reflect interpersonal meaning for ideational and interpersonal metafunctions. Pronoun-based features showed the strongest positive correlations with interpersonal meaning, including personal pronouns (*ppron*; $\rho = 0.28$), first-person singular (I; $\rho = 0.20$), and second-person address (*you*; $\rho = 0.16$). Social reference variables also showed positive correlations with interpersonal meaning, including *Social* ($\rho = 0.22$), *socrefs* ($\rho = 0.18$), *affiliation* ($\rho = 0.11$), and *Clout* ($\rho = 0.19$).

The same variables showed weaker correlations with ideational meaning, including *ppron* ($\rho = -0.02$), I ($\rho = -0.10$), *you* ($\rho = 0.06$), *Social* ($\rho = 0.13$), *socrefs* ($\rho = 0.13$), *affiliation* ($\rho = 0.11$), and *Clout* ($\rho = 0.16$).

Affective and modality-related variables showed comparatively weaker correlations with interpersonal meaning, in-

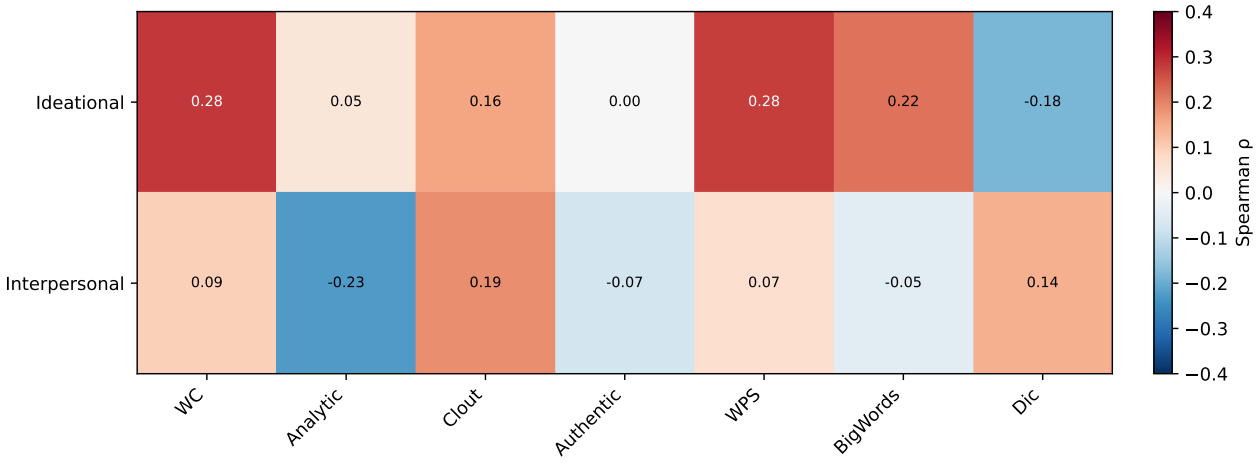

Figure 4: Spearman correlations between SFL metafunctions and LIWC Summary Variables.

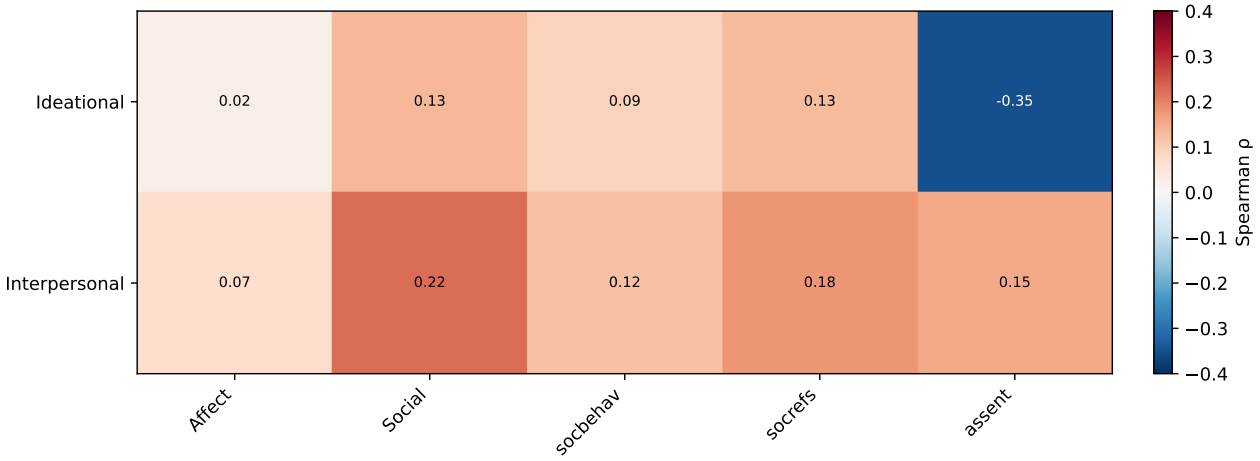

Figure 5: Spearman correlations between SFL metafunctions and LIWC Affective and Social Processes.

cluding *Affect* ($\rho = 0.07$), *tentat* ($\rho = 0.07$), and *negate* ($\rho = 0.06$).

The patterns observed in Analysis 2 support the construct validity of the theory-driven mapping. Variables predicted to align with ideational and interpersonal meaning showed differentiated correlations across metafunctions. This divergence would not be expected if LIWC features reflected only generic verbosity or affect, but instead indicates theoretical alignment with dimensions of meaning. At the same time, the weak and inconsistent performance of cognitive-process variables highlights limits in how these categories map onto interactional reasoning in multilingual classroom discourse.

3.3 Analysis 3: Language, Translation, and Error Analysis

LIWC outputs varied systematically across the original translanguaged, English-only, and Spanish-only transcript conditions, with distinct patterns depending on dictionary choice (Tables 3 and 4).

Using the LIWC-22 English dictionary (Table 3), English-only transcripts showed higher values than the original translanguaged condition for dictionary-based and function-heavy categories, including *Dic* (89.03 vs. 71.28), *Linguistic* (79.82 vs. 62.83), and *function* (55.85 vs. 42.60). The Spanish-only condition showed pronounced reductions in these same variables (e.g., *Dic* = 16.91; *function* = 8.00), while punctuation- and segmentation-related measures increased, including *Analytic* (63.81 vs. 30.43), *Period* (26.74 vs. 12.61), and *AllPunc* (57.59 vs. 42.12). Pronoun- and verb-based categories were near zero in the Spanish-only condition under the English dictionary.

Using the ES-LIWC2007 Spanish dictionary (Table 4), Spanish-only transcripts showed higher values than the original for dictionary match and grammatical categories, including *Dic* (80.70 vs. 28.28), *Funct* (51.59 vs. 19.02), *Verbos* (18.89 vs. 5.36), and *TotPron* (12.72 vs. 4.48). English-only transcripts showed consistently lower values across these same categories. Punctuation-related variables (*AllPunc*,

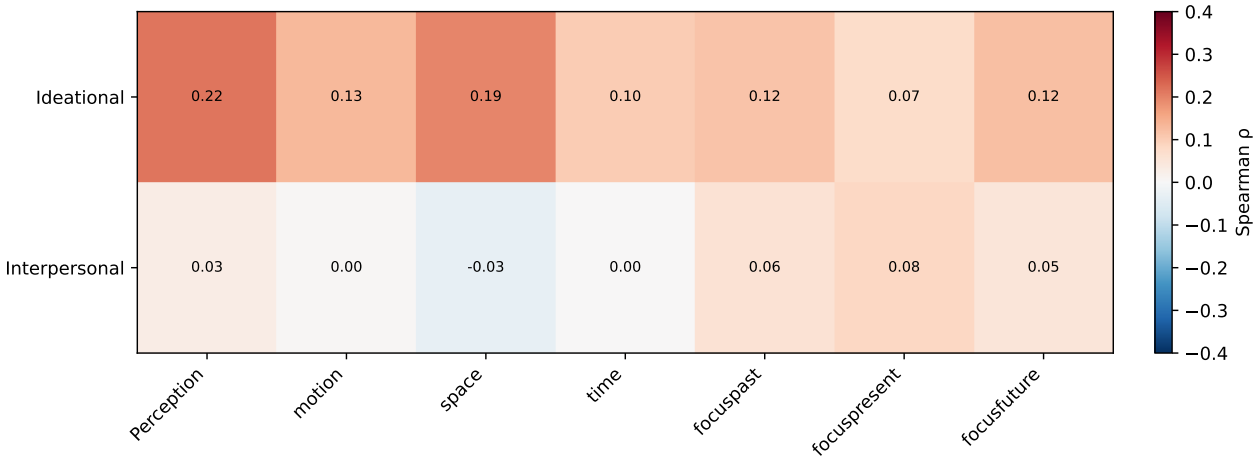

Figure 6: Spearman correlations between SFL metafunctions and LIWC Perception and Time Orientation variables.

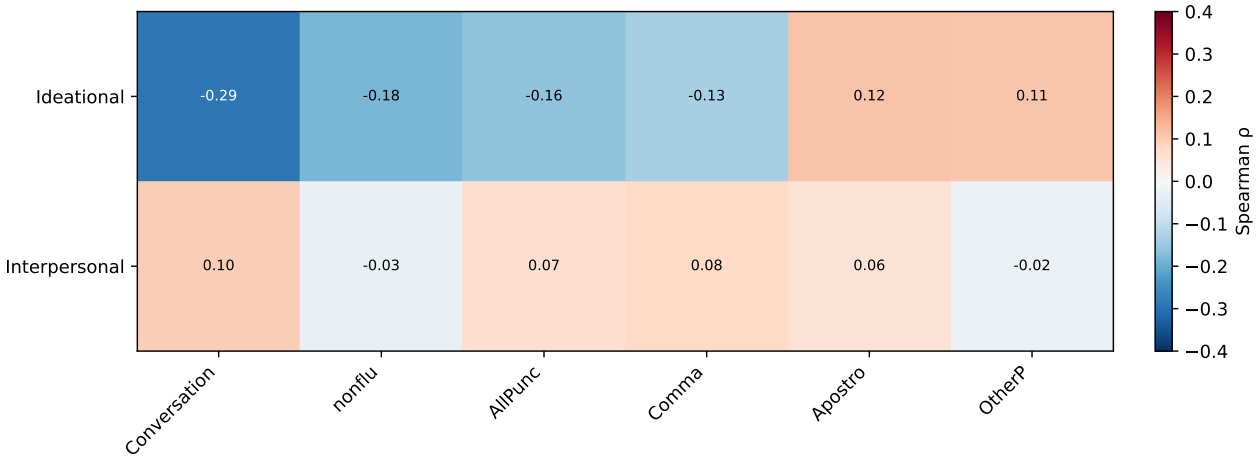

Figure 7: Spearman correlations between SFL metafunctions and LIWC Conversational and Punctuation variables.

Period, *QMark*) showed higher values in the Spanish-only condition across both dictionaries.

Across both dictionary settings, the original translanguaged condition generally fell between the English-only and Spanish-only conditions on most variables (Tables 3–4), indicating that language restriction and translation systematically reshaped LIWC feature distributions.

4. DISCUSSION

This study uses SFL to address a central challenge in EDM: how to improve interpretation of automated linguistic measures in ways that are theoretically grounded and reflect authentic language use, particularly in multilingual STEM classrooms. SFL provides a principled account of how language simultaneously construes experience, enacts social relations, and organizes discourse, making it well suited for analyzing the meaning-making practices of MLLs whose linguistic resources span languages and registers.

Against this backdrop, we examined how psycholinguistic features derived from LIWC align with expert annotations of SFL metafunctions in K-12 multilingual small-group science discourse. By grounding analysis in ideational and interpersonal meaning, the results clarify which dimensions of classroom talk are captured by commonly used psycholinguistic features and which aspects may remain less visible within current analytic approaches.

Across analyses, ideational meaning showed limited alignment with LIWC features. It was most reliably associated with surface measures of elaboration, particularly *WC* and *WPS*. Although often treated as coarse indicators, these measures indexed experiential and explanatory content in collaborative science talk, suggesting that longer and more elaborated turns were more likely to involve ideational meaning. Perceptual and spatial categories (e.g., *Perception*, *space*, *motion*) also showed modest alignment, reflecting the role of observation and spatial reasoning during scientific sense-making.

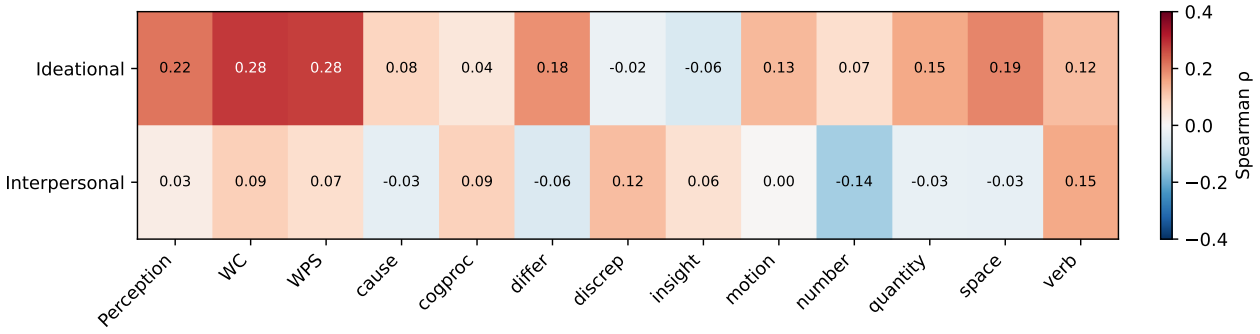

Figure 8: Spearman correlations between LIWC variables and the ideational metafunction.

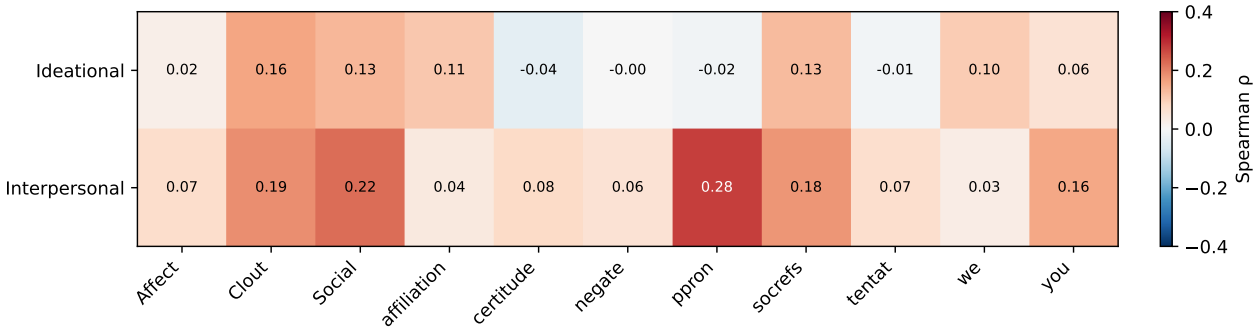

Figure 9: Spearman correlations between LIWC variables and the interpersonal metafunction.

Several LIWC variables commonly interpreted as indicators of conceptual processing showed weak or inverse relationships with ideational meaning. Higher values for *Dic* and aggregate linguistic measures (e.g., *Linguistic*, function word totals, and overall punctuation density) were negatively associated with ideational meaning. In multilingual classroom discourse, lower dictionary coverage may reflect translanguaging practices and domain-specific terminology that fall outside of monolingual dictionary inventories. As a result, utterances that are rich in disciplinary and collaborative content may register as having a lower dictionary match, despite contributing substantively to meaning-making.

In contrast, interpersonal meaning exhibited the strongest and most coherent alignment with LIWC features. Pronoun variables (e.g., *ppron*, *I*, *you*), social reference categories, and summary measures related to social positioning (e.g., *Clout*) showed the highest and most stable correlations across analyses. Agreement markers such as *assent* followed this pattern, showing a positive correlation with interpersonal meaning and a strong negative correlation with ideational meaning ($\rho = -0.35$). This pattern is most clearly reflected in Analysis 2, where variables predicted to align with ideational and interpersonal meaning showed clearly differentiated correlations across metafunctions. These patterns align with SFL accounts in which interpersonal meaning is enacted through stance-taking, evaluation, and participant positioning.

Relatedly, several LIWC categories often interpreted as indexing cognition (e.g., *cogproc*, *discrep*) aligned more strongly with interpersonal than ideational meaning. In dialogic classroom interaction, these features frequently function to signal epistemic stance, hesitation, or negotiation (e.g., "I think," "I don't know," "maybe") within interaction rather than to elaborate scientific explanations. This suggests that LIWC cognitive-process variables in collaborative settings are more closely associated with interactional positioning than with experiential or explanatory content.

Findings from the third analysis sharpen these interpretations by isolating the role of language-bound dictionary assumptions. When multilingual classroom talk was constrained to a single-language representation, the prominence of LIWC features shifted systematically, with greater emphasis on grammatical density, punctuation, and segmentation, and reduced sensitivity to social (e.g., *Social*, *socrefs*, *affiliation*) and experiential (e.g., *Perception*, *space*) categories. These shifts varied by dictionary, indicating that alignment patterns are shaped by how linguistic resources are partitioned across language-specific inventories. The translanguaged condition did not behave as an aggregation of English and Spanish features, but instead exhibited a distinct distribution of LIWC features, suggesting a redistribution of meaning-making resources that is not fully preserved under single-language dictionaries. These findings empirically challenge assumptions that academic reasoning occurs primarily in English while other languages serve only social or supportive functions, showing instead that MLLs use their full linguistic repertoires for both ideational and inter-

personal meaning-making.

Taken together, these outcomes have direct implications for how psycholinguistic features are interpreted and used in EDM models of learning in multilingual classroom contexts. In particular, LIWC categories conventionally treated as indicators of cognition or reasoning consistently aligned with interpersonal meaning in dialogic interaction. As a result, models that do not account for these learner variabilities may underestimate MLLs' knowledge and shape both assessment and downstream instructional decisions in ways that do not reflect their full meaning-making practices [13]. We therefore recommend that LIWC-based approaches more explicitly account for multilinguality, and that future work compare these features with methods that are better suited to multilingual analysis (e.g., parts-of-speech tagging).

Several limitations should be considered when interpreting these findings. The dataset consists of a relatively small number of annotated utterances drawn from focal segments of authentic classroom interactions, which enables fine-grained functional analysis but limits statistical power and generalizability to broader classroom populations. Multilingual classroom discourse highlights a significant limitation of dictionary-based approaches, as translanguaging practices and multilinguality are not fully captured by language-specific resources. In addition, SFL metafunction labels were applied at the utterance level and allowed to co-occur, reflecting the multifunctional nature of classroom talk. While theoretically grounded, this design attenuates feature–label correlations and complicates interpretation. Future work should explore representations that capture temporal context, turn-taking structure, and the development of meaning across turns, including textual and thematic organization, to better align computational features with interactional processes.

5. CONCLUSION

This study uses SFL theory to examine what LIWC features capture in multilingual classroom discourse. LIWC aligns most strongly with interpersonal meaning by capturing stance and social positioning. Ideational meaning is only partially reflected through elaboration and experiential language, while cognitive-process categories show limited alignment with explanatory content. Integrating SFL with computational analysis can support more precise interpretation of linguistic features and the development of methods that capture ideational and interpersonal meaning-making in multilingual learning contexts.

APPENDIX
A. LIWC VARIABLES

Table 5: LIWC variables used in analyses. ID = ideational; IP = interpersonal; (–) = no a priori prediction specified.

Category	Abbrev.	Description / Exemplars	Predicted
Summary Variables			
Word Count	WC	Total number of words.	ID
Analytical Thinking	Analytic	Formal, logical, hierarchical language.	ID
Clout	Clout	Confidence, leadership, social status.	IP
Authenticity	Authentic	Honest, personal, genuine language.	IP
Emotional Tone	Tone	Overall emotional positivity or negativity.	IP
Words per Sentence	WPS	Average sentence length.	ID
Big Words	BigWords	Words with six or more letters.	–
Dictionary Words	Dic	Words matched by LIWC dictionary.	–
Linguistic Processes			
Linguistic Processes	Linguistic	Aggregate function word usage.	–
Function Words	function	Articles, pronouns, prepositions, auxiliaries.	–
Pronouns (total)	pronoun / TotPron	All personal and impersonal pronouns.	–
Personal Pronouns	ppron	I, we, you, they.	IP
First-person singular	I	I, me, my.	IP
First-person plural	we	we, us, our.	IP
Second-person	you	you, your.	IP
Impersonal Pronouns	ipron	it, that, those.	–
Determiners	det	this, that, these.	–
Prepositions	prep	to, with, from, entre.	–
Auxiliary Verbs	auxverb	be, have, do.	–
Conjunctions	conj / Conjunc	and, but, or, porque.	–
Negations	negate	no, not, never.	IP
Verbs	verb / Verbos	Action and relational verbs.	ID
Quantifiers	quantity / Cuantif	many, few, much.	ID
Numbers	number	Numeric digits and number words.	ID
Adjectives	adj	Descriptive modifiers.	–
Cognitive Processes			
Cognitive Processes	cogproc / MecCog	Thinking, knowing, reasoning.	ID
Insight	insight	Realization, understanding.	ID
Causation	cause	Cause–effect relations.	ID
Discrepancy	discrep	Should, would, could.	ID
Tentativeness	tentat	Maybe, perhaps.	IP
Differentiation	differ	Contrast (but, however).	ID
Certitude	certitude	Certainty and confidence markers.	IP
Affective and Social Processes			
Affect	Affect	Emotional expression (happy, sad, angry).	IP
Social Processes	Social	Social interaction language.	IP
Social References	socrefs	References to others.	IP
Social Behavior	socbehav	Helping, talking, sharing.	IP
Affiliation	affiliation	Belonging and connection.	IP
Assent	assent	Agreement markers (yes, okay).	IP
Perception and Time			
Perception	Perception / Percept	Sensory language (see, hear, feel).	ID
Motion	motion	Movement and change.	ID
Space	space / Espacio	Spatial reference.	ID
Past Focus	focuspast	Past tense orientation.	–
Present Focus	focuspresent / Present	Present tense orientation.	–
Future Focus	focusfuture	Future-oriented language.	–
Conversational and Punctuation			
Conversation	Conversation	Informal spoken discourse markers.	–
Nonfluencies	nonflu	Filled pauses and hesitations (um, uh).	–
All Punctuation	AllPunc	Overall punctuation density.	–
Comma	Comma	Comma frequency.	–
Apostrophe	Apostro	Apostrophe frequency.	–
Other Punctuation	OtherP	Punctuation other than periods and commas.	–

A Human-in-the-Loop Pipeline for Multi-Class SRL Classification

ABSTRACT

Annotation of big data is a nontrivial task for learning analytics scholars. Educational constructs drawing from learning psychology, such as self-regulated learning, require theory-grounded domain expertise and cannot be easily inferred from surface features, making annotation time-intensive and difficult to scale. Recent work aims to address this issue by using large language models (LLMs) to annotate data. While this approach can increase the amount of annotated data, evidence suggests that LLMs tend to overgeneralize, based on the examples included in the prompt cases, and misclassify due to a lack of context understanding. To address this, we investigate how human-in-the-loop machine learning strategies can be used to maximize the impact of human annotation by focusing efforts on a subset of data that would benefit most from labeling or relabeling. Utilized data include human-labeled, machine-labeled, and unlabeled student prompts from diverse educational contexts. We compare two active learning methods, loss weighting and their combination on the task of multi-class classification of student-generated text in AI-chatbot interactions. Experiments with a multilingual DeBERTa-based classifier indicate that combining human annotation with selective correction of weak labels can improve performance compared to a baseline trained on available annotated data annotated by humans and LLMs. The human-in-the-loop pipeline mitigates misalignment in labels produced by LLMs, providing a path forward to more responsible and rigorous use of LLMs in educational data annotation tasks.

1. INTRODUCTION

Educational constructs such as self-regulated learning (SRL), motivation, and help-seeking (e.g.,[20, 21, 11]) are widely used as proxies for studying students' learning behaviors. However, these constructs are inherently latent and not directly observable in student interactions; instead, they must be inferred through a theoretically grounded interpretation. Researchers therefore need to operationalize them through observable indicators, such as discourse patterns, behavioral traces, or interaction features, connecting abstract theoretical constructs to empirical data. This process is necessarily interpretative and theory-laden, making annotation less a technical labeling exercise and more an expert-driven analytical task. Producing high-quality annotated datasets is thus essential but also highly time-intensive, costly, and difficult to scale, particularly when expertise in both learning theory and specific educational contexts is required [10]. The strong dependence on expert judgment and contextual understanding further limits the feasibility of substituting expert annotators with crowdsourced approaches without risking reduced validity and theoretical fidelity [15].

These challenges are becoming more pronounced as students increasingly engage with AI conversational agents such as Claude in higher education [7]. Such interactions generate large volumes of rich process data that offer unprecedented opportunities to examine how learning unfolds in AI-mediated contexts. However, the scale, heterogeneity, and context sensitivity of these interaction logs intensify existing annotation challenges. Without robust theoretically grounded annotation frameworks, translating these large-scale student-AI interaction datasets into meaningful insights about learning processes remains highly complex and not straightforward.

To address these challenges, scholars have increasingly explored the potential of LLMs (see, e.g., [17, 1]) to support the annotation of educational data. Their capacity to process large volumes of text suggests a promising pathway toward scaling annotation efforts that have traditionally relied on intensive expert labor. However, a central concern remains how limited expert time and resources can be allocated so that LLM-assisted annotation increases the quantity of la-

beled data without compromising quality, theoretical validity, or interpretability [29]. Emerging research indicates that LLMs can facilitate large-scale annotation while reducing reliance on time-consuming expert coding. However, the reliability and theoretical fidelity of LLM-generated labels remain highly sensitive to prompting strategies, contextual framing, and task specification [9, 23]. Consequently, efficiency gains often risk coming at the expense of validity and alignment with underlying learning theories. These tensions suggest that fully automated annotation is unlikely to be sufficient for theory-driven educational research. Instead, *hybrid human–AI approaches* that strategically combine machine scalability with expert oversight may offer a more viable path forward [9, 19]. The key challenge is therefore not simply automation, but the effective orchestration of human expertise within LLM-supported workflows.

In response, we investigate a human-in-the-loop (HITL) annotation pipeline designed to support large-scale coding of educational datasets while maintaining theoretical rigor. The proposed pipeline integrates active learning techniques (see Section 2.2) to identify uncertain, potentially incorrect, or missing labels and prioritize them for expert review. In parallel, it incorporates loss-weighting strategies that reduce the influence of lower-confidence LLM-generated labels during model training. Together, these mechanisms aim to improve annotation efficiency while preserving validity and theoretical coherence. We evaluate the individual and combined contributions of these components using SRL classification [21] as a case study. SRL provides a particularly suitable testbed because it involves theoretically grounded constructs (e.g., effort regulation and elaboration) that are not directly observable and therefore require interpretative coding. Although the empirical evaluation focuses on SRL, the proposed workflow is intended to generalize to other theory-driven qualitative annotation tasks in education and related domains. This work is guided by the following **research question:**

How much expert involvement is needed for a human-in-the-loop LLM coding pipeline to improve annotation quality over an automated baseline?

This paper makes three **main contributions**:

- a human-in-the-loop pipeline to support a high-quality, hybrid LLM-human coding strategy for SRL prompt classification,
- a comparative evaluation of the effectiveness of the respective components of this pipeline on a dataset,
- practical implications for shifting expert labor from comprehensive and time-intensive coding to targeted supervision and revision of LLM-based coding systems.

2. RELATED WORK

2.1 LLMs for Qualitative Analysis

Recent research has increasingly explored the use of LLMs as tools for qualitative analysis in educational research. This work spans applications such as codebook development [1, 3], deductive coding [18], and the annotation of textual data [9, 29, 32]. Across these studies, LLMs are typically positioned as supports for specific stages of qualitative workflows, with the goal of improving analytical efficiency while maintaining the validity and theoretical grounding of qualitative interpretations.

Evidence from this literature suggests that LLM-supported qualitative coding is most reliable when applied to relatively well-defined and less theoretically complex constructs. As construct complexity increases, model performance becomes more sensitive to how coding tasks are framed and specified. Prompting strategies such as few-shot prompting [17], which combine construct definitions with annotated examples, have therefore been explored to improve alignment between LLM outputs and coding schemes. Under carefully specified conditions and within particular domains, such approaches have enabled LLMs to achieve annotation performance comparable to that of humans [18, 4, 17].

However, limitations become more apparent when LLMs are applied to complex, theory-driven constructs. Prior work reports tendencies toward overgeneralization and mislabeling in such settings, as models may rely on surface-level linguistic cues rather than theoretically grounded categories when assigning codes [17].

These challenges raise concerns about the validity and interpretability of fully automated qualitative coding in theory-intensive educational research.

To mitigate these issues, scholars have begun proposing HITL approaches, in which expert annotation is selectively integrated into LLM-supported workflows [3]. Typically, a subset of the data is manually coded to serve as a ground-truth reference for evaluating LLM-generated labels. Iterative comparisons between human annotations and model outputs can then identify disagreement cases that warrant targeted expert review. Insights from these reviews are used to refine prompts, clarify codebook definitions, and improve alignment between LLM-generated labels and theoretically grounded coding schemes [3].

Despite these advances, important challenges remain. For example, while strong performance on SRL classification has been achieved when models are trained on fully human-coded datasets [33], they often fail to generalize across subject domains or languages. This implies that high accuracy may come at the cost of repeatedly producing large, consistently annotated datasets for each new context. In contrast, more general LLM-based approaches offer greater transferability but may introduce additional noise into generated labels [34].

These tensions highlight the need for approaches that enable systematic validation and refinement of LLM-generated labels without relying on fully human-coded datasets. While prior work has explored HITL strategies primarily through prompt engineering [15] and iterative feedback [3], comparatively little research has examined how LLM-generated annotations can be systematically validated and integrated into theory-driven qualitative coding pipelines at scale.

2.2 Active Learning and Loss Weighting

Active Learning offers a promising approach to maximize the impact of limited human supervision in LLM-based coding tasks. Rather than uniformly reviewing all available in-

stances, an iterative HITL approach is used in which the model actively selects data for annotation based on an uncertainty measurement. A common approach is uncertainty-based sampling, which selects samples with low prediction confidence for human (re)labeling [26].

This selection process is typically embedded within a cycle of model training, evaluation, and targeted relabeling, allowing the training set to be refined progressively.

Hybrid methods that integrate LLM-generated labels with HITL active learning methods are a relatively recent development [24, 14]. These hybrid approaches treat the LLM as a noisy annotator that can scale up to label large amounts of data, while focusing human effort on the relabeling of samples that are likely to have the largest impact on classifier performance. While these methods have shown positive impacts on the performance of general NLP tasks such as topic classification and semantic similarity [14], they have not yet been systematically evaluated in educational contexts.

A complementary approach for managing annotation quality is *loss weighting*, which explicitly accounts for differences in label reliability during model training. Loss weighting assigns increased influence to annotations from more reliable coders (e.g., a human expert), while down-weighting labels generated automatically by LLMs or the model itself. This approach makes it possible to benefit from large volumes of weakly labeled data without allowing noisier labels to dominate the training process [30].

Hybrid LLM-HITL active learning methods, alone or combined with loss weighting, have not been systematically evaluated on the classification of latent, theory-driven educational constructs. Our work aims to fill this gap by evaluating how these methods can reduce annotation costs under a limited budget by focusing expert effort on informative instances and appropriately integrating labels of differing quality, as measured by their impact on the accuracy of a mDeBERTa-v3-base model [8] trained on data processed through different stages of the pipeline.

2.3 SRL for AI-Mediated Learning

To analyze how learners regulate their learning when interacting with generative AI chatbots, the SRL theoretical lens [36, 22] may be adopted. SRL guides learning through metacognitive skills in three main phases. The forethought phase represents the planning stage of learning, in which learners outline goals for a study session. It is followed by the performance phase, where the planned activities are executed. The final phase is self-reflection, in which learners review their performance in relation to the goals and adjust the behavior [36]. To operationalize this three-phase model in the setting of generative AI chatbot use in computer science education, the SRL framework by Pintrich et al. [22] may be adapted [31, 2]. This results in seven SRL categories for the classification of user prompts: rehearsal (adjusted), organization, elaboration, help-seeking, effort regulation, critical thinking, and non-SRL behavior. Table 1 provides definitions for each category.

3. METHODS

Against this background, this study addresses the problem of prioritizing samples for human annotation to identify and correct incorrect labels generated by a weak reviewer (e.g., an LLM) under a fixed budget for human supervision and given an initial set of human-annotated reference labels.

The problem was formulated as a multi-class classification problem with seven mutually exclusive classes, where each instance is assigned at most one categorical label. This dataset reflects a real-world, low-resource scenario, characterized by strong class imbalance, with some classes being represented only by a few labels.

3.1 Datasets

The study draws on multiple datasets representing different cultural contexts, educational settings, and subject domains at higher education institutions in Sweden [31], Germany [25], and South Korea [6]. The subject areas covered include foundational programming, scientific writing, and chemistry. The selected datasets consist of end-to-end, multi-turn dialogues between individual students and an LLM. The data was collected during self-study activities such as homework assistance, reflection, and exam preparation. Each dataset was collected under distinct instructional conditions: in Sweden, 10 students used ChatGPT without explicit instructions, generating 2445 messages. In Germany, 212 students used an unspecified LLM chatbot, generating 2335 messages, and in South Korea, 131 students interacted with a GPT-3.5 through a writing platform (RECIPE [5]), generating 1913 messages. The language used to communicate with the LLM was English in 4179 messages, German in 1600, Swedish in 567, and Korean in 70 (counted after the removal of duplicates). Although the data include complete dialogic interactions, the analysis treats individual student prompts as the unit of analysis to ensure comparability across datasets. Prompts were used verbatim, maintaining orthographic and grammatical errors.

In addition to these empirical datasets, a synthetic dataset was created to address rarely represented SRL constructs. Specifically, the *rehearsal* construct occurred only three times across the empirical data. To supplement this limitation, additional examples were generated using an iterative multi-shot prompting approach with the OpenAI GPT-5.2-2025-12-11 model following Litake et al. [16]. All synthetically generated instances were manually reviewed before inclusion. The prompt used for data generation is provided on OSF. The codebook for the project can be found in Table 1.

3.2 Datasets and Preparation

The different datasets were joined by maintaining the original dataset name, the student prompt, and, if present, the SRL label. Except for the Swedish dataset, the datasets do not include SRL annotations. In addition, we make use of a dataset reported in a master's thesis [37], which contains chat transcripts from self-study activities of Swedish STEM students together with LLM-generated SRL codes. The labels were normalized across datasets, and the source of each label was encoded based on the originating dataset as human-labeled, LLM-labeled, or unlabeled. The data cleaning and preparation consist of four subsequent steps:

1. Text cleaning: All prompts were cleaned before being

Table 1: Codebook of the theoretical lens used.

Construct	Description	Example
Rehearsal	Addresses drill-and-practice behavior, where students repeat learning material to memorize it. In prompt-based interaction, rehearsal may be reflected by repeated or highly similar prompts across learning sessions, including quiz-like activities where the student receives questions from a chatbot.	*"hi, i would like to review about the results of my quiz. I got wrong in this question [...]"*
Organization	Prompts in which students request summarization, support for structuring and editing content, such as spelling correction or writing assistance.	*"Then, what is the repeted word in my essay?"* or *"make this paragraph coherence and better for the grammar[...]"*
Elaboration	Prompts where students ask for additional information to better understand a concept by making connections between ideas.	*"What does Counter do?"* or *"What do linearly recursive, end-recursive, and non-linearly recursive mean?"*
Help-seeking	Prompts in which students directly request solutions or explicit guidance to solve a task.	*"def f4(m, n): if m == 0: return n + 1 elif n == 0: return f4(m - 1, 1) else: return f4(m - 1, f4(m, n - 1)) y = f4(1, 1) What is the return value? Number of calls? What is the recursion type?"*
Effort regulation	Prompts in which students ask for additional resources or explanations aimed at persisting with learning tasks.	*"For example, if my work's limitation is that it only works at the specific domain (graphic design), how can I write my limitation well?"*
Critical thinking	Prompts where students evaluate information, question assumptions, or reflect on the validity of responses.	*"No this is definitively wrong."* or *"Should it not be 5 due to our prior result?"*
Non-SRL behavior	Prompts that cannot reliably be coded as rehearsal, organization, elaboration, help-seeking, effort regulation, or critical thinking. This includes greetings and acknowledgments.	*"nope, thats it. thanks"* or *"Hello"* or *"Great, thanks"*.

further processed. This includes Unicode normalization, removal of control characters, leading and trailing whitespace, line breaks, and the removal of boilerplate tags and phrases originating from accessibility-related user interface components of the chatbot (e.g., file upload prompts).

2. Label normalization: The existing labels were normalized with, e.g., different capitalization, manually reviewed, and joined into canonical labels.

3. Duplicate handling: Rows with missing prompts were removed from the dataset. Exact duplicates, which are defined as a row with an identical combination of text, label, and label sources, were collapsed into a single instance. Rows with identical text but conflicting labels were merged by keeping the human annotation if present. In the case of conflicting LLM-generated labels, the rows were collapsed and marked as unlabeled, dropping the LLM lables .

4. ID Generation and Language Detection: In the last preprocessing step, a UUID was generated for each row using the cleaned text and the dataset name. Using *langid* the language of each prompt was detected, limited to the languages present in the datasets (Swedish, German, English, and Korean).

3.3 Baseline Model

As a baseline, the multilingual mDeBERTa-v3-base model [8] was fine-tuned as a text classifier for SRL label prediction at the prompt level using the Hugging Face Transformers library with the standard sequence classification architecture. Individual student prompts were used as the unit of analysis, with a single categorical SRL label per input. Following an initial hyperparameter tuning, inputs were tokenized using the corresponding pretrained tokenizer and truncated to a maximum sequence length of 128 tokens, with dynamic padding applied during batching. Fine-tuning was performed for five epochs using an AdamW-style optimizer with a learning rate of 3×10^{-5}, a weight decay of 0.01, and a warm-up ratio of 0.06, following a cosine learning-rate schedule. A per-device batch size of two with gradient accumulation over eight steps resulted in an effective batch size of sixteen. All trained checkpoints were retained and manually inspected for analysis, rather than selecting a single checkpoint based on an automated validation criterion. Following Sokolova and Lapalme [27], the evaluation metric used was $F1_{macro}$ due to the class imbalance.

3.4 Loss Weighting

To prioritize human-annotated instances x_i^{Hu}, a per-instance loss weight was introduced. Each training instance x_i is assigned a strictly positive weight $w_i > 0$. Human-annotated samples receive unit weight, while LLM-labeled samples are either assigned a fixed downweighting factor $w_{LLM} < 1$, treated as a tuned hyperparameter, or weighted individually using w_i^{LLM}. A normalization $\sum_i w_i$ with ℓ_i as the standard cross-entropy loss for x_i, limits the effect of weighting to the relative contribution of individual samples, leaving the overall gradient scale unchanged.

$$\mathcal{L} = \frac{\sum_{i=1}^{N} w_i, \ell_i}{\sum_{i=1}^{N} w_i}.$$

3.5 Active Learning for Label Acquisition

Active learning was applied exclusively to the unlabeled subset of the dataset. At each iteration of the label acquisition (LA), an uncertainty score was computed for all unlabeled instances using predictive entropy following [26]. The 50 instances with the highest entropy values were selected for manual annotation. The newly annotated samples were added to the training set, and the model was retrained using the same architecture and hyperparameter configuration as in the baseline setup. This procedure was repeated in iterative cycles until the annotation budget of 200 labels was exhausted.

3.6 Active Learning for Label Correction

To address the varying LLM annotation quality, a weighting approach was applied and evaluated. It is assumed that LLM-labeled instances x_i^{LLM} located close to clusters of human-annotated instances x_i^{Hu} in the model embedding space are more likely to be correct than instances that are further away, as discussed by Kontonatsios et al. [12]. Such instances were prioritized for label correction (LC) by human review.

This approach was implemented using the cosine similarity. For each instance x_i with one label set L_i, an embedding $e_i \in \mathbb{R}^d$ was computed in a shared d-dimensional embedding space using the mDeBERTa transformer encoder [8]. For each SRL label l, a normalized centroid c_l was defined as the mean embedding of all x_i^{Hu} instances assigned to the label l. These centroids were then used to define per-instance weights.

$$w_i^{LLM} = \max\left(\max_{l \in L_i} \exp\left(-\frac{1 - e_i^\top c_l}{\sigma_l}\right), \varepsilon\right),$$

where σ_l describes the median cosine similarity between x_i^{Hu} of label l and its centroid. Human-annotated instances are assigned unit weight ($w_i = 1$), and all weights are lower-bounded by a small constant$w_i \leftarrow \max(w_i, \varepsilon)$.

To identify candidates for human review, the w_i metric was combined with similarity-based indicators defined as

$$\delta = d_{\text{nearest}} - d_{\text{self}}$$

where d_{self} is the cosine similarity between x_i^{LLM} and the centroid c_l that corresponds to the assigned label, and d_{nearest} is the similarity to the closest centroid of a non-assigned label. A larger value of δ indicates a candidate for mislabeling. Based on the w_i metric, a review flag was assigned when w_i was in the lowest decile and prioritized by δ.

3.7 Evaluation Study

An evaluation study was concluded to assess the effectiveness of loss weigting, active learning through label acquisition (LA), and active learning for label correction (LC). For this purpose, after the initial cleaning described in section 3.2, a baseline dataset was constructed from the existing human-labeled instances x_i^{Hu}, the machine-labeled instances x_i^{LLM}, and unlabeled instances $x_i^{\emptyset}$. The resulting dataset includes 6416 samples with 836 x_i^{Hu}, 2016 x_i^{LLM} and 3564 $x_i^{\emptyset}$.

This dataset was used to train the baseline model and was iteratively extended in batches of 50 instances through additional human annotation and re-annotation of x_i^{LLM} instances. In total, this process resulted in ten distinct datasets summarized in Table 2.

An initial split was defined using only the $\boldsymbol{x_i^{\text{Hu}}}$ instances for the test and validation sets, while for the training set, the x_i^{LLM} and remaining $\boldsymbol{x_i^{\text{Hu}}}$ were used. The split between training, validation, and test sets was 80/10/10, while ensuring that all classes were present in the validation and test datasets. We first randomly select the latter sets and use the rest of the data to fill up the training set. The training set was iteratively improved by adding human labels to unlabeled instances (LA approach) or correcting LLM-labeled instances (LC approach), while the validation and test sets were unchanged.

Table 2: Dataset composition across annotation strategies: label acquisition (LA) and label correction (LC). (50–200 = human additional annotations or reviews).

	Dataset	$\boldsymbol{x_i^{\text{LLM}}}$	$\boldsymbol{x_i^{\text{Hu}}}$	$\boldsymbol{x_i^{\emptyset}}$
	Baseline	2016	836	3564
Iteration 1	LA 50	2016	886	3514
Iteration 2	LA 100	2016	936	3464
Iteration 3	LA 150	2016	986	3414
Iteration 4	LA 200	2016	1039	3364
Iteration 1	LC 50	1966	886	3564
Iteration 2	LC 100	1916	936	3564
Iteration 3	LC 150	1866	986	3564
Iteration 4	LC 200	1816	1036	3564
	Combined	1816	1236	3164

4. RESULTS

As indicated in Table 3, a macro-F1 score of 0.328 and an accuracy of 0.352 are achieved for the baseline model. For the baseline dataset, instance-based loss weighting w_i leads to improved performance compared to the unweighted, but this is not the case for the augmented datasets LA-200 and LC-197. For these, a fixed assignment weight, determined via grid search, instead results in higher performance. The weight increased with the number of iterations during which labels were added or corrected, indicating that the dataset quality improved.

Table 3: Performance across iterations, strategies, and weighting (none, per-instance, and best constant $w^\star$).

Iteration	Dataset	Loss weighting	Macro F1	Macro Recall	Accuracy
	Baseline	none	0.328	0.323	0.352
	Baseline	per ins.	0.350	0.377	0.383
	Baseline	$w^\star = 0.4$	0.371	0.396	0.379
1	LA-50	none	0.365	0.400	0.380
2	LA-100	none	0.382	0.407	0.393
3	LA-150	none	0.327	0.353	0.352
4	LA-200	none	0.371	0.395	0.380
4	LA-200	per ins.	0.329	0.349	0.440
4	LA-200	$w^\star = 0.3$	**0.402**	**0.418**	0.490
1	LC-50	none	0.324	0.355	0.419
2	LC-100	none	0.320	0.344	0.407
3	LC-150	none	0.350	0.345	0.457
4	LC-197	none	0.366	0.391	0.453
4	LC-197	per ins.	0.334	0.366	0.430
4	LC-197	$w^\star = 0.9$	0.375	0.398	0.467
4	Combined	none	0.386	0.405	0.494
4	Combined	per ins.	0.326	0.354	0.448
4	Combined	$w^\star = 0.9$	0.395	0.412	**0.498**

For active learning through LA, macro-F1 scores increase across successive LA iterations up to LA-200, except for a performance drop for LA-150, for which $F1_{Macro}$ falls below the baseline, likely reflecting sensitivity to sampling effects, class imbalance, and label noise [26]. For LA, instance-based loss weighting does not provide additional gains, whereas a fixed loss weight resulted in the highest overall $F1_{Macro} = 0.402$ for LA-200.

Similar results are observed for active learning through LC,

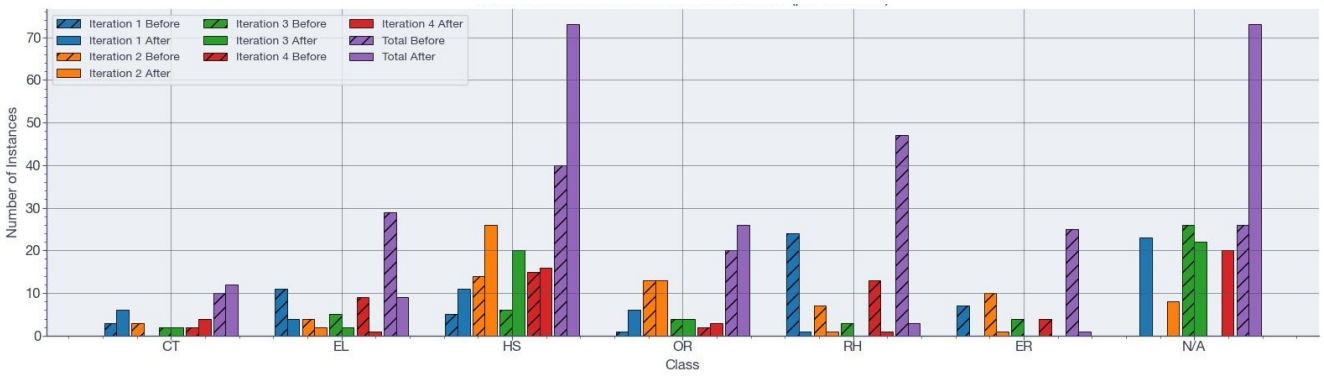

Figure 1: Class-wise label distribution for each LC Iteration and in Total, with Before/After bars indicating the labels among the 50 reviewed instances for that iteration. CT = Critical Thinking, EL = Elaboration, HS = Help Seeking, OR = Organization, RH = Rehearsal, ER = Effort Regulation, and N/A = no applicable SRL label.

outperforming the baseline from LC-150 and up. As in the LA setup, instance-based weighting performs worse than no weighting, and a fixed loss weight performs the best. Across the four LC iterations, 197 instances (out of 200, three samples were inadvertently removed due to a procedural oversight but were identified during the final write-up) were selected for review. Of these, 120 instances (60.9%) were identified as having been incorrectly labeled and were corrected. The distribution of corrected labels indicates an overgeneralization within the LLM-generated labels, with SRL labels having been assigned by the LLM, although the content did not align with any construct in the codebook. The absolute number of *Non-SRL* was hence drastically increased (+48) after label correction. In addition, the numbers of *Help seeking* (+34), *Organization* (+7), and *Critical Thinking* (+2) labels were also increased, while those of *Rehearsal* (-44), *Effort Regulation* (-25), and *Elaboration* (-20) were decreased. This pattern was consistent across all relabeling iterations and also corresponds to the shares in the newly labeled data in the LA iterations. The number of identified labeling errors decreased across successive iterations, from 42 (out of 50) in the first iteration to 28 in the second, 24 in the third, and 26 in the final iteration. Figure 1 summarizes the class-wise label distribution before and after reviews.

The combination of 200 newly labeled instances and 197 revised instances results in slightly higher overall accuracy compared to either the LA or LC configurations alone. A fixed loss weight provides performance close to the best-performing configuration, while instance-based weighting again performs poorly in $F1_{Macro}$.

5. DISCUSSION

LLMs have the potential to contribute meaningfully to scaling the labor-intensive process of qualitative coding of educational data when positioned as provisional labelers. Their outputs function as 'weak' and potentially noisy signals that require systematic human review rather than serving as trusted sources of annotation [35]. Addressing the research question, performance, naturally, normally increases with progressive human addition or correction of labels. In our experiment, the best results were obtained when adding 200 more human labels (LA-200) or combining addition and correction (Combined). Adding or reviewing fewer labels did not guarantee outperforming the baseline, as shown by LA-150, LC-50 and LC-100 (no weights). Reviewing 200 LLM annotations (10% of LLM labels) or adding 200 human annotations (24% increase) to a dataset that still consists of twice as many LLM-labeled and thrice as many non-labeled instances is a reasonable effort to improve performance (respectively, +11.6% and +13.1% in $F1_{Macro}$). HITL expert involvement is hence both necessary and effective in complementing or correcting LLM-generated labels. These findings extend prior work on utilizing LLMs for qualitative coding tasks [3, 17] with an approach to address limitations of overgeneralization.

Consistent patterns in how the proposed pipeline affects model performance were revealed. Active learning through LA shows overall performance gains under a fixed annotation budget, even if fluctuations occur in the LA-150 iteration, while active learning through LC improved results compared to the baseline from LC-150 and up. Without loss weighting, LC-197 is at par with LA-200 (0.366 vs. 0.371), suggesting that, under a fixed human annotation budget, correcting existing 'weak' labels can be as effective as expanding the dataset (note that 120 – not 200 – labels were corrected in LC-197). The higher label quality reduces the need for strong downweighting of LLM-generated labels ($w* = 0.9$ for LC vs. $w* = 0.3$ for LA).

Fixed loss weighting improves performance and indicates that LLM-generated labels can provide useful information if their imperfection is taken into account. Instance-based weighting worsened performance, suggesting that it relies on similarity estimates in a learned embedding space optimized for classification rather than geometric accuracy, making cosine similarity sensitive to regularization and feature scaling effects [28]. As a result, the corresponding weighting signals can become unstable during training. Distance-weighted cosine similarity is suggested to mitigate these effects [13].

This study has several limitations related to the scope of the empirical evaluation. The analysis is restricted to a single domain, which limits the generalizability of the findings to other domains. In addition, the evaluation considers only a single model architecture. While the proposed pipeline

explicitly addresses label noise and class imbalance, its effectiveness for rare constructs remains constrained by the availability of reliable human annotations. Furthermore, the study does not explicitly account for human factors such as reviewer fatigue or inter-rater reliability, which may influence the robustness of HITL annotation processes. Finally, we acknowledge that the use of existing datasets from different cultural and task contexts may limit the generalizability due to cross-context differences that may lead to different student–LLM interaction patterns.

Future work should examine the applicability of the proposed pipeline across additional domains, modeling settings, and annotation budgets. More generally, the interaction between automated labeling, human review, and data quality warrants further investigation beyond fully supervised annotation regimes. To further validate LLM-generated labels, the use of cosine similarity as an additional signal alongside inter-rater reliability (kappa) should be explored, which may help assess label consistency and improve robustness in diverse contexts. Such pipelines can be embedded into existing qualitative coding workflows to support targeted human review, building on prior work [3, 34].

The findings indicate that the effectiveness of LLM-supported annotation in educational research depends on structured human participation. Although LLM-generated labels provide a helpful boost, loss weighting combined with explicit mechanisms to involve human experts for label correction provides additional value. Improving the quality of existing weak labels via human involvement can be similarly effective as acquiring new labels. Taken together, these results show that a human-in-the-loop pipeline that treats LLM-generated labels as 'weak' signals and prioritizes targeted human correction can scale theory-driven annotation under a fixed annotation budget while preserving theoretical rigor.

ABSTRACT

In deductive content analysis, text data is categorized into previously developed themes. We present a three-GenAI consensus model for deductive analysis of text data. In the model, the same prompt and data are provided to three GenAIs, and their agreement with each other is used to cluster data to facilitate deductive coding by researchers. First, data is split into trial and corpus sets. Trial data is used to iteratively revise the prompt provided to the three GenAIs. Next, the revised prompt is provided to the three GenAIs to deductively code the larger corpus data. Based on the responses of the three GenAIs, data is clustered into three groups: all three GenAIs agree, only 2 GenAIs agree, and all three GenAIs disagree. The data in the three clusters is separately coded by researchers, with the GenAI coding in each cluster used to narrow coding choices for the data in that cluster. To illustrate the use of the three-GenAI consensus model, we used it to deductively analyze 496 student responses to a self-directedness survey that had been previously coded by researchers. We calculated that the researchers would have saved nearly 70% of coding time if they had used the three-GenAI consensus model first. Deductive analysis of text data is labor-intensive, involving multiple researchers and multiple iterations. The three-GenAI consensus model enables researchers to redistribute time from exhaustively analyzing all data to closely reviewing only the data that does not clearly fit any of the themes of deductive analysis.

1. INTRODUCTION

Qualitative content analysis is used to explore meanings, themes, and patterns in text, allowing researchers to understand social reality in a subjective, but scientific manner [25]. Research questions in qualitative investigations aim to probe the "what", "why", "who", "when", "where", and "how" of social interactions or human behavior, rather than quantifying occurrences or measurements to test hypotheses [10, 14]. Qualitative content analysis can be inductive or deductive [2]. In inductive (bottom-up) methods, researchers identify and describe themes that emerge during an iterative process of analyzing bodies of text. In deductive (top-down) methods, researchers use previously developed sets of themes or models or theories as a coding scheme/book to analyze large bodies of text, attempting to fit the data into existing themes. Deductive coding can be binary (whether a theme exists or not) or multi-level (identify one of several themes).

Qualitative analysis techniques are iterative in nature, involving multiple passes through the data to build a deeper, more refined understanding of the subject matter [19]. For example, in deductive coding, data analysis can result in the refinement of existing themes as well as the identification of new themes, which can lead to the recoding of already coded data. For large data sets, this iterative process is labor-intensive [20], and involves the time-consuming work of abstraction and interpretation [11].

Research teams doing qualitative data analysis must collaboratively review notes and do close readings of text [17]. Many of the software tools available for qualitative data analysis (such as ATLAS, Dedoose, NVivo) assist with data organization only and not with the data interpretation done by the research team. Furthermore, they are based on a subscription model that may not be within reach for all researchers. With the recent advent of powerful generative AI tools (GenAI) that can quickly find patterns in large bodies of text, researchers now have a new tool to conduct qualitative analysis. A drawback of GenAI is that they are prone to hallucinate, which reduces the reliability of their responses.

In order to reliably use GenAIs for deductive analysis, we propose a three-GenAI consensus model that uses three GenAIs

instead of one, uses the consensus in their responses instead of raw responses, and uses the consensus to narrow choices for deductive coding by researchers. We present the savings in time realized using this model and present a case study to illustrate its use and highlight its savings.

2. RELATED WORK

Qualitative analysis has been used extensively in computing education research. It has been used to identify themes in code interviews [9], student reflection papers [3], survey responses [6], online forum discussions [15], transcripts of think-aloud interviews [16, 23] and semi-structured interviews [8], among others. Typically, qualitative analysis involves processing text data, and involves multiple researchers engaged in a labor-intensive iterative process. As a result, qualitative analysis is hard to scale to larger data sets because of the time, cost and complexity involved.

Machine learning (ML) techniques have been used to process educational data (e.g., see a systematic literature review in [5]). Techniques used to analyze text data include latent semantic analysis [22], bag-of-words [7], etc. GenAI improves upon these traditional ML techniques in that it does not require significant training.

Given that GenAI has been publicly available for just over three years, the use of GenAI for qualitative coding is new. GenAIs have been used for both inductive and deductive coding. In one study, ChatGPT was used to help in codebook development during an inductive-deductive process [21]. In another study, ChatGPT-4 was found to be valuable for inductively developing codebooks, but human involvement in the process was deemed essential [1].

For deductive coding, prompts based on codebook were found to be more effective than those based on examples - combining GenAI (GPT-3) with expert-drafted codebooks achieved fair to substantial agreement with expert-coded results [24]. In another study, codebooks designed for researchers were found to need iterative refining for use with GenAIs [4]. For binary deductive coding, zero-shot prompting, i.e., not providing examples in the prompt, yielded good results for well-defined constructs, but was not as effective when the constructs were context-dependent [12, 13].

We propose a model to use three GenAIs for deductive coding. In the model, we propose to use a prompt based on the codebook designed for researchers. We use it in zero-shot mode, although this is not required for the model to work. The model narrows coding choices and helps researchers redistribute time from exhaustively analyzing all data to closely reviewing only the data that does not clearly fit any of the themes of deductive analysis.

3. THE THREE-GENAI CONSENSUS MODEL

In deductive qualitative analysis or coding, researchers use a previously developed set of themes, called a codebook, to identify the theme in each data item. In this text, we will refer to a data item as a statement, and a theme as a category.

We propose to use three GenAIs to aid in deductive multi-level coding, in what we refer to as the *three-GenAI consensus model*, as follows:

1. Shuffle the data and split it into a trial set (10-15% of the data) and corpus.
2. Draft a codebook-based prompt. Use an iterative cycle of deductively coding trial data using the three GenAIs, followed by revising the prompt provided to them, until the deductive coding of trial data is satisfactory in terms of inter-rater reliability with researchers.
3. Use the revised prompt to have the three GenAIs code the statements in the corpus data.

For both trial and corpus data, the consensus among the three GenAIs is used to split the data into three clusters:

- *Unanimous*, the set of statements that all three GenAIs code/categorize the same;
- *2-agree*, the set of statements that exactly two GenAIs categorize the same - this excludes the statements in unanimous cluster;
- *3-disagree*, the set of statements that all three GenAIs categorize differently.

The three clusters are used by researchers for deductive coding as follows:

- Unanimous: Researchers first conduct binary coding of each statement to check whether it belongs in the category identified unanimously by all three GenAIs. If not, then and only then do they consider the remaining categories for coding the statement;
- 2-agree: Researchers first consider the two categories identified by the three GenAIs: one by two concurring GenAIs and the other by the dissenting GenAI. If neither category applies to the statement, they consider the remaining categories for coding the statement.
- 3-disagree: Researchers first consider the three categories identified by the three GenAIs and consider the rest of the categories only if these three do not apply to the statement.

The utility of this model depends on whether the correct category of a statement is among the one/two/three categories identified by the three GenAIs in the three clusters.

In the three-GenAI consensus model, note that:

1. Three GenAIs are used instead of one to reduce the effect of hallucinations on the outcome.
2. The consensus in the responses of the three GenAIs is leveraged.

3. The clusters obtained based on the degree of consensus among the three GenAIs are used to reduce the number of categories researchers first consider when coding statements.

4. The final categorization of statements is still done by researchers and not GenAIs. The three-GenAI model is used to facilitate the qualitative coding done by researchers.

We will next present a case study of using the three-GenAI consensus model for multi-level deductive coding. In order to illustrate its feasibility and merit, we will use it to verify coding previously done by researchers. The case study will provide an example of using the model and its utility in facilitating deductive coding in practical settings.

4. CASE STUDY

For our case study, we used data from a study of the self-directed disposition of undergraduate computing students [18]. The study was conducted between 2022 and 2024 in five computing courses at four higher education institutions in the US. Data was collected from 264 students who consented to participate in the study. The study was approved by the institutional review boards of all four institutions (IRB-FY2022-53, IRB-FY2022-6, Protocol# 2021-08-005, and IRB-627).

In the study, students were presented the following definition of being self-directed: "Learn new tools/techniques on your own to complete a task, even when the tool/technique is only minimally used or discussed in class, and you may not receive additional credit just for learning it." They were then asked to respond to an open-ended question: "Describe an example of you being self-directed when completing this assignment. Otherwise, describe the circumstances that prevented you from being self-directed." Students were asked to respond to this question after multiple assignments in a course.

A total of 496 responses were collected and deductively coded using the codebook shown in Table 1 developed by researchers [18]. This coding by researchers (henceforth referred to as *prior coding*) was used to verify the correctness of coding of the three-GenAI consensus model and for calculating the time saved by using it.

We used three GenAIs to which we had ready access: Claude Sonnet 4.5, ChatGPT 5.2 Pro and Gemini 3. The prompt statement provided to the GenAIs was structured as follows:

1. **Persona:** GenAI was asked to act as a "qualitative analysis expert".

2. **Goal:** The goal was to conduct deductive coding of statements written by undergraduate students in computing courses in response to the open-ended question listed earlier in this section.

3. **Context:** The definition of self-directed disposition given to students [18] was listed next.

4. **Instructions:** GenAI was asked to identify one of the first eight categories in the codebook (Table 1) for each statement.

Table 1: Codebook for *self-directed* disposition [18]

Category	Description
Utilizing external resources	Selecting additional material or reaching out to people to support one's own learning
Learning necessary material	Demonstrating a process to learn new material, including concepts, tools, techniques
Working independently	Doing the problem or task without assistance from others
Assessing oneself	Recognizing one's own capabilities, deficits, or lack of expertise, and appropriateness of learning strategies
Planning ahead	Planning actions before execution, either in terms of time or designing sub-steps
Applying useful techniques	Applying techniques that are helpful with learning and doing the work
Completing the assigned work	Achieving the goal of completing the work
Reviewing against expectations	Reviewing one's own actions and outcomes against provided expectations, guidelines, or goals
Not applied	Factors prevented student from being self-directed
Not pertinent	Insufficient information to indicate self-directed behavior

5. **Codebook:** The entire codebook was provided. GenAI was asked to consider the categories in the order listed in the codebook, as was done by researchers during their coding.

6. **Constraints:** GenAI was further instructed to do the following:

   (a) If a statement belonged to more than one category, identify the dominant category as determined by intent.

   (b) If a statement did not contain any category, code it as "Not pertinent".

   (c) If a statement explained why self-directed was not applied, code it as "Not applied".

   (d) Ignore the word "self-directed" in a statement unless the statement is about not being self-directed.

7. **Purpose:** GenAI was told that its analysis would be used by computing education researchers to summarize how students understood self-directed disposition in undergraduate computing courses.

The prompt was zero-shot—no examples were provided for the categories—to avoid introducing potential biases based on those examples.

The 496 responses were shuffled and split into 74 trial statements (15%) and 422 corpus statements. The same prompt was provided to all three GenAIs and they were instructed to deductively code the 74 trial statements. Based on the responses of the three GenAIs, we clustered the 74 trial statements into unanimous, 2-agree and 3-disagree, as shown in Table 2:

- Unanimous cluster consisted of 52 trial statements (70.3% of trial data). The three GenAIs identified the same category as prior coding for 42 of the 52 statements

Table 2: Agreement among the three GenAIs

Data	Total	Unanimous	2-Agree	3-Disagree
Trial	74	52 (70.3%)	18 (24.3%)	4 (5.4%)
Corpus	422	289 (68.5%)	109 (25.8%)	24 (5.7%)
Total	496	341 (68.8%)	127 (25.6%)	28 (5.6%)

Table 3: Trial Statement Clusters

Cluster	Total	Same as Prior Coding
Unanimous	52	42 (80.8%)
2-Agree	18	6 + 5 (61.1%)
3-Disagree	4	1 (25%)
Total	74	54 (73%)

(80.8%), as shown in Table 3. The inter-rater reliability between the three GenAIs and prior coding was substantial (Cohen's kappa = 0.7508).

- 2-agree cluster contained 18 trial statements (24.3% of trial data). As shown in Table 3, the two concurring GenAIs identified the same category as prior coding for 6 statements and the dissenting GenAI identified the same category as prior coding for 5 more. In 61.1% of the 2-agree cases, the correct category was one of the two identified by the GenAIs.
- Only 4 out of 74 trial statements were in the 3-disagree cluster. For one of the 4 statements, one of the three GenAIs identified the same category as prior coding, as shown in Table 3.

Given the large percentage of trial statements in unanimous cluster (70.3%) and the substantial inter-rater reliability of coding in this group (0.7508), we chose not to iteratively improve the prompt. We provided the same prompt to the three GenAIs and instructed them to deductively code the 422 corpus statements. The cluster sizes for corpus statements are shown in Table 2.

- Unanimous cluster consisted of 289 corpus statements (68.5% of corpus data). The three GenAIs identified the same category as prior coding for 238 of the 289 statements (82.4%), as shown in Table 4. The inter-rater reliability between the three GenAIs and prior coding was substantial, with Cohen's kappa of 0.7678.
- 2-agree cluster contained 109 corpus statements (25.8% of corpus data). As shown in Table 4, the two concurring GenAIs identified the same category as prior coding for 57 statements and the dissenting GenAI identified the same category as prior coding for 32 more. In 81.7% of the 2-agree cases, the correct category was one of the two identified by the GenAIs.
- Only 24 out of 422 corpus statements were in the 3-disagree cluster. For 20 out of the 24 statements (83.3%), one of the three GenAIs identified the same category as prior coding, as shown in Table 4.

Table 4: Corpus Statement Clusters

Cluster	Total	Same as Prior Coding
Unanimous	289	238 (82.4%)
2-Agree	109	57 + 32 (81.7%)
3-Disagree	24	20 (83.3%)
Total	422	347 (82.2%)

Note that in all three corpus clusters, the correct category was one of those identified by the GenAIs for at least 80% of the statements.

For the statements for which the GenAIs did not identify the prior coding category, we conducted an additional validation step: we had two researchers independently re-identify the category, and compared their 1 - 2 (for 2 researchers) categories against prior coding category as well as the 1-3 categories identified by GenAIs in unanimous/2-agree/3-disagree clusters. The category identified by the two researchers was one of the 1-3 categories identified by GenAIs instead of the prior coding category in 52 - 61% of the statements in unanimous cluster (the range based on the two researchers' independent coding), 74 - 89% of 2-agree cluster and 71 - 100% of 3-disagree cluster. This suggests that the statements for which the three GenAIs did not identify the prior coding category were harder to categorize for researchers too.

In the next section, we will calculate the time saved by using the three-GenAI consensus model for qualitative coding.

5. TIME SAVINGS

Assume the data set contains s statements (data items), the codebook contains c categories (themes), and during multi-level deductive coding, it takes one unit of time to consider one category for one statement. Therefore, full-fledged deductive coding of s statements takes $s * c$ units of time.

If n_u, n_a and n_d are the number of statements in unanimous, 2-agree and 3-disagree clusters, respectively:

$$s = n_u + n_a + n_d$$

If p_u is the percentage of statements in unanimous cluster whose GenAI categorization is correct, the time taken t_u to categorize all the statements in the cluster is

$$t_u = n_u * (p_u * 1 + (1 - p_u) * c)$$

For p_u percentage of statements in unanimous cluster, researchers need to consider only one category. For the remaining $(1 - p_u)$ percentage of statements, after confirming that the category chosen by the GenAIs is incorrect, researchers must consider the remaining $(c - 1)$ categories.

Similarly, if p_a is the percentage of statements in 2-agree cluster for which the correct category is one of the two picked by the three GenAIs, the time taken t_a to categorize all the statements in the cluster is:

$$t_a = n_a * (p_a * 2 + (1 - p_a) * c)$$

Finally, if p_d is the percentage of statements in 3-disagree cluster for which the correct category is one of the three

picked by the three GenAIs, the time taken t_d to categorize all the statements in the cluster is:

$$t_d = n_d * (p_d * 3 + (1 - p_d) * c)$$

The time needed to deductively code using the three-GenAI consensus model, as a percentage of the time needed to code without the model is:

$$\frac{t_u + t_a + t_d}{s * c}$$

The percentage reduction in time is given by:

$$\frac{n_u * p_u * (c-1) + n_a * p_a * (c-2) + n_d * p_d * (c-3)}{s * c} \quad (1)$$

The larger the number of categories c, and the greater the percentages p_u, p_a, and p_d, the larger the savings in time. Note that the savings are *per researcher*, and can be substantial considering that typically, three or more researchers are involved in deductive coding.

In the case study in Section 4, combining trial and corpus data, we have from Table 2:

$$n_u = 341, \quad n_a = 127, \quad n_d = 28, \quad s = 496$$

From Table 1, we have $c = 10$. From Tables 3 and 4, we have:

$$p_u = \frac{42 + 238}{52 + 289} = 0.82$$

$$p_a = \frac{11 + 89}{18 + 109} = 0.79$$

$$p_d = \frac{1 + 20}{4 + 24} = 0.75$$

Note that p_u, p_a, and p_d are all large: at least 75%, one of the requirements for large savings in time. If the three-GenAI consensus model had been used for prior coding of the case study dataset, the time spent on coding could have been reduced by 69.88% *per researcher* involved in prior coding.

6. DISCUSSION

We proposed the three-GenAI consensus model for multi-level deductive coding of qualitative data. We used a codebook and prior coding of a dataset of 496 statements to demonstrate the use of the model for deductive coding and the savings in coding time that can be realized using the model. In the future, we plan to start with a codebook, use the three-GenAI model to cluster data into unanimous, 2-agree and 3-disagree, and then deductively code statements in the three clusters.

The percentage reduction in time (expression 1, Section 5) is a theoretical maximum. Using the model requires the following preparatory steps, all of which take additional time and effort: designing the prompt, splitting dataset into trial and corpus, using trial data to iteratively refine the prompt, using the refined prompt to deductively code corpus data, and tabulating the responses of three GenAIs into unanimous, 2-agree and 3-disagree clusters for both trial and corpus data. However, for large data sets, the time and effort needed for these preparatory steps will be largely offset by the time saved by researchers coding the data using the three-GenAI consensus model.

An advantage of the model is that researchers can reallocate some of the time saved coding statements in unanimous and 2-agree clusters to carefully code the statements in 3-disagree cluster. Statements in the 3-disagree cluster are typically the statements that are harder to code because they land on the boundary between categories. Prior research has found that the statements GenAI finds difficult to code are the same as those that researchers find difficult to code [12].

The unique features of the three-GenAI consensus model are: in order to counter the hallucinatory potential of GenAIs, three GenAIs are used instead of one; the consensus in their responses is leveraged; and the clusters obtained based on the degree of consensus are used to reduce the number of categories researchers need to consider when coding data. The final coding is still done by researchers; GenAIs ease their task so that researchers can spend more time on statements that are harder to code.

The Three-GenAI consensus model could have saved nearly 70% of deductive coding time in the case study. However, the case study involved coding statements that were responses to a single specific survey question. Therefore, the context of the data was both limited and clear, which may have played to the strengths of the three-GenAI consensus model. In contrast, deductive coding is often applied to large and ill-structured text such as interview transcripts, reflection papers, and forum discussions in which the context is large and diffuse. The applicability and benefits of using the three-GenAI consensus model to such data remain to be explored.

We considered only one category per statement. When multiple categories applied to a statement, we considered only the dominant category. If we were to consider *all* the categories in each statement, qualitative coding using the three-GenAI consensus model would have to consider sets of categories instead of individual categories. Unanimous, 2-agree and 3-disagree clusters would be based on set intersection, complicating the application of the model.

We used a zero-shot prompt. A significant performance improvement has been observed going from zero-shot to one-shot prompt [24]. We plan to evaluate the improvement in inter-rater reliability and time savings of the model with one-shot prompt in the future.

In another study with a different data set, we observed how the stochastic nature of GenAIs affects their behavior when used for deductive coding: when three GenAIs were instructed to code the same data set with the same prompt twice, a week apart, the inter-rater reliability (Cohen's kappa) between the two runs was substantial, but not perfect: 0.82 for Claude Sonnet 4.5, 0.78 for ChatGPT 5 Pro and 0.74 for Gemini 2.5 Flash. Given this observation, it may be beneficial to pick the category identified by a GenAI for a statement as the best of n deductive coding runs of the GenAI.

ChatGPT offered an excellent critique of the inter-rater reliability readiness of the codebook (Table 1). Although the three-GenAI consensus model does not include codebook improvement as part of the process, we would like to enhance the model in the future by using trial data to improve the codebook before refining the prompt.

ABSTRACT

The contract termination remains a persistent challenge in vocational education and training (VET), yet existing dropout prediction models overlook the tri- stakeholder dynamics inherent to apprenticeships, i.e., involving the apprentice, workplace master, and training provider. We propose **ESPM** (Ensemble Stacking with Perception-aware Meta-learning), a two-stage architecture that combines gradient boosting base learners with a neural meta-layer encoding stakeholder presence patterns and perception gaps. For interpretability, we introduce the Engagement Asymmetry Index (EAI) and an Engagement-Performance Decomposition module. Evaluated on 3,511 apprenticeship contracts (143, 983 skill evaluations) from the French VET system, ESPM achieves an F1 of 72.21% and a recall of 71.92%, outperforming nine baselines. Interpretability analysis reveals that employer-related features dominate predictions (52.2%) and engagement features outweigh performance features (56.1% vs. 43.9%), challenging the conventional focus on academic grades for dropout prediction.

Dropout Prediction, AI in Education, Educational Data Mining, Vocational Education, Apprenticeship Training

1. INTRODUCTION

VET systems play an important role in addressing the demands of the labor market by developing skilled workforces. Apprenticeship, which combines theoretical and practical training, has emerged as an effective structure to facilitate the transition from education to employment across numerous countries [8, 20]. France offers two main forms of VET or work-study programs (fr. *formation en alternance*): (1) Apprenticeship (fr. *Apprentissage*), i.e., employment contract combining vocational training with paid work experience; and (2) Professionalization Contract (fr. *Contrat de Professionnalisation*), i.e., employment contract targeting specific groups. The apprenticeship system has witnessed a significant rise in popularity, with over 800,000 active contracts recorded in 2023, reflecting a massive increase over the last few years [13]. Despite this rise, the contract termination rate in apprenticeships is concerning, with approximately 30% of contracts ending prematurely at the national level [14]. In France, the apprenticeship system is governed by frameworks like the National Directory of Professional Certifications (fr. *Répertoire National des Certifications Professionnelles*, *RNCP*), which serves as a key pathway for youth employment, with over 500,000 contracts annually. This growth was driven by the 2018 reform, which increased financial incentives, simplified administrative procedures, expanded eligibility criteria, and created industry-led funding mechanisms [16]. French national agency *France Compétences*[1], established by the same law that governs the VET and apprenticeship. Its key functions include: regulating training quality and costs, managing the RNCP, distributing funding for apprenticeships and VET, ensuring that qualifications meet labor market needs, and evaluating or monitoring the effectiveness of the system. Digital training booklets (fr. *livrets de formation*) like Campus skill, Kwark, Sheldon skills, STUDEA, track apprentice progress against these competency frameworks, providing a structured record of skills acquisition throughout the training program.

In general, apprenticeship programs have been demonstrated to be an effective method to prepare youth for the labor market through a combination of classroom instruction and

workplace training. However, contract rupture or dropout has been a major problem in apprenticeships, which affects both learners and training organizations. The dropout rates in apprenticeship programs are significantly high and range between 10% and 20%, depending on the sector and program level. The high dropout rate has negative economic consequences beyond individual disappointment. Employers invest their resources in training and supervision, but they face disruption in operational continuity while generating recruitment costs [12]. The providers or training institutions face difficulties in managing program quality metrics, and experience reduced funding tied to completion rate as well [3]. The apprentices or learners often lead to an extended period of unemployment, diminished motivation, and long-term career setbacks due to contract termination [9]. Previous ML studies for dropout prediction have focused on learners in a higher education context and considered several individual-level factors such as academic performance, demographic data, and social and economic aspects. In contrast, apprenticeship education is a triad (tri-stakeholder) structure, which involves (1) apprentice (student) who learns skills and has personal characteristics, (2) master (employer) who provides workplace supervision, task allocation, and practical skills development, and (3) training provider (tutor) who delivers lessons in the classroom, sets the curriculum, and provides institutional support. The concept of apprenticeship inherently involves multi-stakeholder contexts where the learner and other stakeholders may hold asymmetric engagement or have varying levels of expectations. This difference may increase the risk of students dropping out. However, current studies of dropout prediction often neglect these dynamics and adopt the perspective of a single stakeholder, either the learner or the institution. By narrow framing and focusing only on immediate context, several issues may be overlooked, which include (1) critical interactions, (2) perception gaps encountered between apprentices, employers, or providers, (3) engagement asymmetries where stakeholders participate at different intensities, and (4) misalignment between training content and workplace needs.

Our study addresses these gaps by proposing the Ensemble Stacking with Perception-aware Meta-learning (ESPM), a two-stage ensemble approach that models tri-stakeholder dynamics through: (1) a neural meta-learner incorporating perception gap and stakeholder presence features, and (2) two interpretability modules, the EAI computing seven engagement-derived features for SHAP analysis, and Engagement - Performance decomposition that is responsible for separating the predictive signal into engagement-versus-performance and stakeholder-specific contributions. The approach is evaluated on one of the French training booklets' real-world datasets that contains 3,511 apprenticeship triads encompassing 143,983 skill evaluations from a VET platform. The proposed work is evaluated and compared with nine top baseline models, among which ESPM achieves the superior F1 (72.21%) and recall (71.92%). Beyond performance gain, ESPM provides interpretability through EAI-enhanced SHAP analysis, revealing that employer features contribute 52.2% among all stakeholders, engagement features outweigh performance metrics (56.1% vs 43.9%), and students with engagement patterns "apprentice-only" show 41.7% dropout rates, nearly 5× higher than triads where engagement pattern is complete.

The **major contributions** of this paper are fourfold: (1) a domain-specific feature set incorporating RNCP certification details, tri-stakeholder evaluations, and perception gap features, (2) ESPM's architecture, which fuses base learners with domain-specific encoders for stakeholder presence and perception gaps, (3) EAI and decomposition modules, enabling granular interpretability, and (4) empirical validation on real-world apprenticeship data, demonstrating that disengagement between stakeholders occurs before performance decline. The rest of the paper is structured as follows: Section 2 discusses a literature review. In section 3, we share the details of the dataset and preprocessing. Section 4 presents the detailed methodology. In 5, we share the details of the experimental setup. Section 6 highlights the results, and section 7 concludes the paper.

2. LITERATURE REVIEW

The ML application to dropout prediction has experienced significant growth. The use of gradient boosting methods consistently demonstrates strong performance on structured educational data. [5] adopted gradient boosting to identify GPA and credit hours to retain students, while [2] achieved more than 0.85 AUC score using an XGB model on higher education data. In [18], the study reinforces these findings by demonstrating that LightGBM and CatBoost with Optuna hyperparameter tuning outperformed the traditional approaches. The authors in [15] have also achieved state-of-the-art results by incorporating the ADASYN resampling approach with CatBoost on Moodle log data. In a recent meta-synthesis by [4], the authors analyzed 70 studies and 666 dropout variables. They confirm that prior research is mainly focused on individual-level dropout features while neglecting the learning environments of the workplace, which is a critical gap in the context of apprenticeship.

Some recent studies also confirm that gradient boosting methods often achieve similar or exceed the performance as compared with deep learning-based approaches while using tabular datasets [17, 10]. On the other side, ensemble methods, specifically the stacking architecture where a meta-learner is used to combine base model predictions [19], have shown promising results for capturing complementary strengths of the model. Recent work studied a neural meta-learner that learns non-linear combination functions [11], but these approaches remain domain-independent without incorporating task-specific knowledge into their architecture. [21] introduced a transformer-based stacking approach that uses an attention mechanism to dynamically integrate base classifier predictions. The research studies that specifically address dropout in apprenticeships remain sparse. The authors in [9] found that factors like prior education, training sector, and age have a significant effect on the likelihood of non-completion in England. [12] concluded in their work that employer training quality significantly affects retention in Switzerland. In France, [1] highlights the variation across qualification levels but notes the limited availability of data capturing the experience of apprenticeship. A recent report [7] emphasizes the urgency of this problem. They documented that in England, approximately 40% apprentices fail to complete their courses. The concept of perception gaps has been studied in educational psychology [6], but their integration into predictive models is limited. In our work, we address these gaps through four major contribu-

tions. First, we develop tri-stakeholder features to capture engagement patterns from the perspectives of all three stakeholders, which directly overcomes the challenge identified by [4] regarding the workplace learning environment gap. Second, we introduce a perception-aware neural meta-learner that encodes stakeholder presence patterns, perception gaps, and domain knowledge directly into the model architecture. Third, we propose the EAI in dropout prediction as a separate interpretability module that enables SHAP to decompose predictive contributions across stakeholders. Fourth, we develop an Engagement-Performance Decomposer to distinguish engagement and performance-related features, revealing that dissengagement precedes performance decline.

3. DATASET

The French apprenticeship system operates as a form of alternating training, where the contracts span is typically 12-36 months. During training, the learner spends most of their time in the workplace. Skill evaluations by stakeholders are a core component of monitoring throughout the contract. Along with three primary stakeholders (Student, Master, and Tutor) in each contract, there is another stakeholder in some contracts (less consistently implemented), called the LEA (Livret Électronique d'Apprentissage) manager, who oversees the digital apprenticeship portfolio. During the program, each stakeholder assesses the apprentice's competencies across various skill domains by recording scores.

Data Collection and Pre-Processing: Our dataset is obtained from one digital booklet system for apprenticeship management and is subject to confidentiality and data protection agreements. The study analyzes fully anonymized data, collected as part of standard educational practice and handled with institutional data protection policies. All personally identifiable information (PII) related to students, institutions, and workplaces is removed before analysis. The study uses secondary analysis of de-identified data and does not require institutional review board (IRB) approval under our institution's guidelines for educational research. The anonymized records of apprenticeship contracts initiated between 2020 and 2023. The raw data contains 143,983 individual skill evaluation records encompassing 3,529 unique triads (contracts), 6,179 unique skills, and 2,953 unique students. The unique skills contained 407 distinct skill categories, which we consolidated into 10 broad skill domains (e.g., technical skills, communication, professional attitude, etc.) through keyword-based mapping on French skill descriptions to reduce dimensionality while preserving domain-specific predictive signals. In data cleaning, we dropped the records where the apprentice ID or skill evaluation score is missing. The overall stats of the dataset after cleaning are presented in Table 1. Individual evaluations were aggregated to the contract level. All the contracts are strictly ordered by start date within each student to prevent data leakage.

Overall Features: The raw features in the dataset are mainly related to demographic, contract, and skill evaluations. The Table 2 summarizes the overall 53 features used in our experiments, organized by category, stakeholder group, and data source. The features belong to three different sources: (1) *Raw* features used directly from the database, (2) *Scraped* features obtained by web scraping the RNCP[1] registry to fetch RNCP meta-data like total skill blocks/skill counts,

Table 1: Summary of the Apprenticeship Evaluation Dataset

Category	Details
Dataset size	
Total skill evaluation records	143,550
Apprenticeship triads (contracts)	3,511
Unique apprentices/students	2,935
Unique skills	6,130
Original skill categories	407
Mapped skill categories	10
Contract characteristics	
Repeat-apprentice triads	1,070
Triads with prior rupture history	116 (3.3%)
Dropout contracts	367 (10.5%)
Completed contracts	3,144 (89.5%)
Class imbalance ratio	∼8.6:1
Evaluation distribution	
Apprentice (self): triads/evaluations	2,815 / 77,872
Tutor: triads / evaluations	252 / 5,192
Master: triads / evaluations	2,507 / 55,651
LEA/Manager: triads/evaluations	154 / 4,835

Table 2: Summary of Feature Groups by Category and Source

Category	Group	Count	Source
Contract & Demo.	Shared	5	Raw
Student History	Apprentice	2	Raw
Skill Evaluation	Shared	6	Raw
Self-Evaluation	Apprentice	5	Raw
Master Evaluation	Employer	5	Raw
Perception Gap	Shared	1	Raw
Skill Categories	Shared	10	Raw

RNCP Certification	Provider	8	Scraped/Eng.
Interaction Features	Shared	6	Engineered
Total	—	**53**	—

and number of organizations that offer any RNCP, etc., and (3) *Engineered* features computed by transforming the raw features. The group column refers to the features ownership within the triad stakeholders, including *Apprentice* features that purely belong to student history and self-assessment, *Employer* features refer to workplace master evaluations, *Provider* features represent training institute and RNCP related data, and *Shared* features apply across all stakeholders to capture cross interactions. This group distribution or stakeholder mapping is defined for the ESPM to compute asymmetry patterns and perception gaps. The target variable *broken_contract* is binary (0 = retained, 1 = dropout) and is separate from 53 input features. The original dataset contains more than 54 columns, from which we exclude all the non-predictive identifiers, leaky and sparse features with coverage below 25% (including tutor and LEA evaluation statistics), as in most of the triads, tutor and LEA evaluations are missing. Despite low coverage, binary engagement indicators of both stakeholders are retained in the features as the presence/absence signal of their evaluation, which carries meaningful information regarding triad completeness.

4. PROPOSED APPROACH

The ESPM employs a novel two-stage architecture to predict dropout in apprenticeship. ESPM leverages the complementary strengths of multiple gradient boosting algorithms while incorporating domain-specific knowledge of tri-stakeholder dynamics that are inherent to apprenticeship. The model is

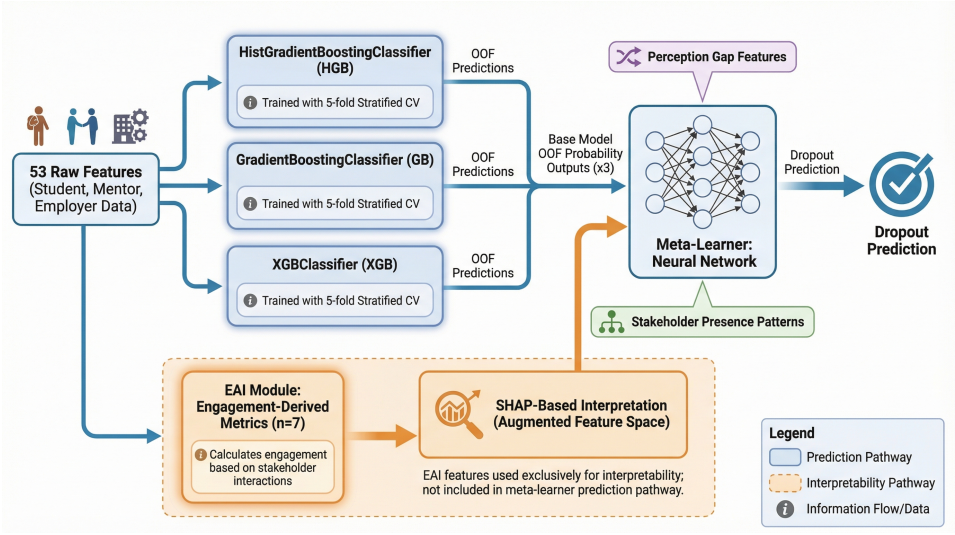

Figure 1: Stage 1 (S1): Base model ensemble (HGB, GB, XGB) generates OOF predictions. Stage 2 (S2): Perception-aware meta-learner combines predictions with domain-specific features. The EAI module (orange box) operates separately for interpretability.

designed using two complementary components: (1) a **two-stage prediction module** that combines the gradient boosting ensembles with a perception-aware neural meta-learner, and (2) an **Engagement Asymmetry Index (EAI) module**, which helps to provide interpretability through engagement analysis. The overall architecture of the ESPM is presented in Figure 1.

ESPM uses separate modules for prediction and interpretability. The prediction module is designed using a two-stage stacking architecture. In stage 1 (S1), an ensemble of gradient boosting models trains on the complex feature interactions to learn from the complete feature set. In stage 2 (S2), a neural network-based meta-learner combines base models' predictions with presence and perception-aware features to generate final dropout probabilities. Separately, we also computed EAI engagement metrics by using the EAI module, which is exclusively for SHAP-based analysis and risk stratification. The EAI features are not fed into the meta-layer for predictions to ensure clean separation between prediction accuracy and model interpretability. The design and module separation reflect our finding that EAI features are valuable for understanding the dynamics of stakeholders but do not contribute to predictive performance (see ablation results in section 6.1).

4.1 S1 - Base Model Ensemble

In ensemble stacking, we used three gradient boosting classifiers with class weighing, including (1) Histogram-based Gradient Boosting (HGB), (2) Gradient Boosting (GB), and (3) Extreme Gradient Boosting (XGB), which serve as base learners. The selection of classifiers is based on their complementary learning characteristics and their ability to efficiently handle imbalanced classes. The diversity of base models helps to capture different patterns of the data. Each base model is trained using 5-fold stratified nested cross-validation to generate out-of-fold (OOF) predictions, which help to avoid data leakage. For fold k, model trained on folds $\{1, \ldots, K\} \setminus \{k\}$ to generate predictions for samples in fold k. This produces an $n \times 3$ matrix of OOF predictions, where each entry is the predicted dropout probability P (dropout) that later serves as meta-features for stage 2. The ensemble produces a prediction matrix $\mathbf{P} \in \mathbb{R}^{n \times 3}$ where each row represents probabilities generated from all three base models.

4.2 S2 - Perception-Aware Meta-Learning

The meta-learner is a feed-forward neural network structure that combines base model predictions with additional domain-specific features to encode stakeholder dynamics. Unlike generic stacking approaches that combine base predictions, ESPM processes three distinct input streams via specialized encoders, including base predictions, perception gaps, and a presence mask. The **base predictions** are the OOF probability outputs of base models (XGB, GB, HGB), processed through a prediction encoder (Linear $\rightarrow$ ReLU $\rightarrow$ Dropout). The **perception gaps** are the 3 raw input features, extracted from the original 53 feature set (1. self_vs_master_gap (apprentice vs master perception gap): mean self evaluation - mean master evaluation (e.g., apprentice rates their skills at 4.2/5.0, while master rates them at 3.0/5.0, the gap is +1.2, indicating overconfidence). 2. fe_gap_magniture: the absolute value of the perception gap ($|1.2| = 1.2$, where a large value (>1.0) regardless of direction, indicates strong misalignment). 3. fe_self_master_interaction: product of self_mean and master_mean) that are passed through a gap encoder (Linear $\rightarrow$ Tanh $\rightarrow$ Dropout) to make the meta-layer aware of perception gaps. The **presence mask** is a binary vector [1 (always true for apprentice), has_master_eval (employer participation flag), has_provider_eval (institutional engagement flag)] that indicates the participation of stakeholders in the evaluation, processed through a pattern encoder (Linear $\rightarrow$ ReLU) to capture the completeness of the triad. The three representations are concatenated to generate a combined vector. The generated vector representation is passed to an attention layer that produces weights over the three base models, which helps to enable context-dependent model combination. Finally, the predictor network produces the final logit by processing the concatenation of raw base

predictions and encoded predictions through a feed-forward network (Linear → ReLU → Dropout → Linear). The architecture allows the meta-learner to use perception gap and presence context to weight base model results, while maintaining access to raw and encoded prediction information.

4.3 EAI Module for Interpretability

We introduce the EAI to identify the imbalanced participation level of each stakeholder group in the triad. In step 1, we compute the **stakeholder engagement score**, for s, where $s \in \{\text{apprentice, employer, provider}\}$. We compute a normalized score in two steps, **a.** Sum relevant (engagement) features of the stakeholder from the original 53 feature set.

$$\text{raw}_s = \sum_{f \in F_s} x_f.$$

The features include all three stakeholders (1) Apprentice (Fs): self_count (self-evaluation frequency), has_self_ eval (participation flag), self_mean (average self-score). (2) Employer (Fs): master_count (master evaluation frequency), has_master_ eval (participation flag), master_mean (average master score). (3) Provider (Fs): has_tutor_eval (tutor participation), has_lea_ eval (LEA manager participation). **b.** Apply min-max normalization across all contracts

$$e_s = \frac{\text{raw}_s - \min(\text{raw}_s)}{\max(\text{raw}_s) - \min(\text{raw}_s)}$$

This produces engagement scores in $[0, 1]$. In step 2, **Asymmetry Calculation**, it uses the vector of engagement score $\mathbf{e} = [e_{\text{app}}, e_{\text{emp}}, e_{\text{prov}}, e_{\text{lea}}]$ to compute EAI as the coefficient of variation

$$\text{EAI} = \frac{\sigma(\mathbf{e})}{\mu(\mathbf{e}) + \epsilon}$$

where σ denotes the standard deviation and μ denotes mean, and $\epsilon = 0.01$ prevents division by zero. The higher EAI score indicates strong asymmetry or one-sided engagement, while the value closer to zero shows balanced engagement across stakeholders. In step 3, we derive **interaction features** from the engagement scores: app_emp_sync $= 1 - |e_{\text{app}} - e_{\text{emp}}|$ (measuring apprentice-employer alignment), eng_completeness (proportion of stakeholders with engagement > 0.1), and eng_gap $= \max(\mathbf{e}) - \min(\mathbf{e})$ (capturing the range of engagement). The computed seven features are used for SHAP-based interpretability analysis, enabling decomposition of stakeholder-wise feature importance and engagement-versus-performance categories.

4.4 Meta-Learner Training

The perception-aware meta-learner is trained using BCE (binary-cross-entropy) loss with class weighing to handle the imbalance ratio. Early stopping is also applied with patience to prevent overfitting. The patience hyperparameter is tuned in the range 5 to 20 during optimization.

5. EXPERIMENTAL SETUP

All the experiments are implemented using Python 3.12, PyTorch 2.1, scikit-learn 1.4, and the Optuna hyper-parameter tuning is utilized for all baselines and the proposed approach, with 15 trials each. To evaluate ESPM, we compared it with **nine baseline classifiers**, including Logistic Regression (LR), Random Forest (RF), Balanced Random Forest (BRF), GB, HGB, XGB, LightGBM (LGB), CatBoost (CB), and AdaBoost (AB). All the models are evaluated using 5-fold stratified nested cross-validation: for each fold, the data split of 80% train and 20% test is performed. To avoid data leakage from repeat triads, folds are grouped by student ID to ensure that all contracts from the same student remain in the same fold to prevent student-level history (e.g., previous_ruptures_count) from leaking into the test set. The fixed random seed (42) is also used to ensure identical splits across all experiments. To evaluate the performance and considering the class imbalance issue, we have used multiple complementary evaluation metrics, Area under ROC curve (AUC) mean for ranking ability, average F1 score (threshold-optimized), average Precision and Recall for imbalanced classification. Considering the importance of identifying at-risk students, recall is prioritized as missing an at-risk student has a higher cost than a false alarm.

Table 3: Performance comparison (mean across 5 folds)

Model	AUC	F1	Precision	Recall	Specificity
ESPM	**0.9253**	**0.7221**	**0.7300**	**0.7192**	**0.9675**
HGB	0.9259	0.6978	0.7360	0.6730	0.9701
XGB	0.9255	0.6900	0.6846	0.7026	0.9611
GB	0.9235	0.7070	0.7338	0.6835	0.9710
LGB	0.9223	0.7001	0.7071	0.6946	0.9662
CB	0.9207	0.7076	0.7320	0.6866	0.9701
RF	0.9188	0.6651	0.6449	0.7025	0.9513
BRF	0.9136	0.6513	0.6164	0.7054	0.9452
AB	0.9074	0.6701	0.6815	0.6621	0.9634
LR	0.8812	0.5828	0.6016	0.5832	0.9500

6. RESULTS AND DISCUSSION

The Table 3 illustrates the overall performance of ESPM and the baseline models. ESPM achieves the highest F1 (0.7221) and recall (0.7192), while maintaining strong precision (0.7300) and specificity (0.9675). It correctly identifies 71.9% of at-risk students compared to 67.3% by the best baseline HGB (as per AUC), representing a 6.8% relative improvement in recall. While the F1 improvement appears modest, its practical impact is significant in apprenticeship. With the highest recall, ESPM identifies additional at-risk students across the 5-fold evaluation, and considering the high cost of dropout, even a small gain in recall justifies the added architectural complexity. For the CFA managing thousands of contracts annually, such improvements could prevent additional dropouts, providing meaningful improvement for both institutional outcomes and student success. The improvement comes with a favorable trade-off, as ESPM achieves higher recall at the cost of slightly lower precision in a context where missing at-risk students carries a higher cost than unnecessary monitoring. Noticing baseline models' pattern, gradient boosting methods (HGB, XGB, GB, LGB, CB) cluster tightly in AUC (0.9207-0.9259), confirming literature findings that these implementations achieve similar accuracy on well-engineered features. LR substantially underperforms (AUC=0.8812), indicating that non-linear interactions matter for this task.

6.1 Ablation Study

To understand the contribution of each component, we performed systematic ablation studies comparing four ESPM variants: (1) ESPM (proposed), (2) ESPM-GapsOnly (re-

Table 4: Ablation study results

Variant	F1	Recall	AUC
ESPM	**0.7221**	**0.7192**	**0.9253**
ESPM-PresenceOnly	0.7207	0.7029	0.9252
ESPM-GapsOnly	0.7171	0.7166	0.9245
ESPM-Baseline	0.7200	0.7165	0.9244

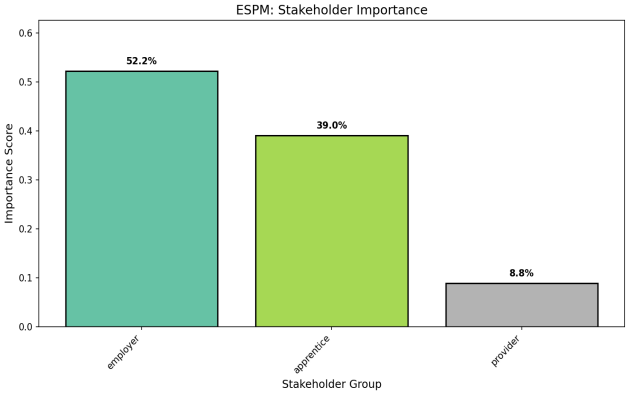

Figure 2: Stakeholder-wise Overall Feature Importance

moves stakeholder presence mask), (3) PresenceOnly (removes perception gap features), and (4) ESPM-Baseline (removes both perception gaps and presence). The study shows that ESPM configuration achieves superior F1 (0.7221) and recall (0.7192). The overall comparative results are shown in Table 4. ESPM's domain-specific design adds value beyond generic stacking by explicitly encoding tri-stakeholder structure directly into the meta-learner. Removing presence mask and perception gaps declines performance and indicates that these components capture patterns that base models alone miss. Results also show that combined features contribute to superior performance as compared to either alone. The results show that explicitly encoding apprenticeship structure through perception gaps and presence patterns improves predictions beyond what generic ensemble learning achieves.

6.2 Interpretability Analysis

SHAP analysis is applied on the 60-feature space (53 raw + 7 EAI features) to identify which stakeholder features contribute most to the prediction task. As the ESPM meta-layer is not directly interpretable, we use a separate HGB classifier as a surrogate model, because it achieves nearly identical performance to ESPM. HGB is trained on 60 feature set solely for interpretability analysis using SHAP TreeExplainer. Analysis results in Figure 2 show that employer-related features are 52.2% of total predictive features, while the stakeholder importance for apprentice is 39.0%, and Provider features are 8.8%. It shows that workplace dynamics/employer features (52.2%) exceed apprentice and provider combined, with master_count (evaluation frequency) as the top predictor. This suggests that monitoring employer engagement is the primary risk signal. The low provider contribution (8.8%) partly reflects sparse coverage (7.2% tutor evaluation rate), but it also indicates that institution-related features are less diagnostic than workplace interactions.

Table 5: Top Engagement (Eng.) vs Performance (Perf.) Features based on SHAP Importance (Imp.) Score

Eng. Features	Score	Perf. Features	Score
master_count	0.156	master_mean	0.089
total_eval_count	0.142	overall_skill_mean	0.072
self_count	0.128	self_vs_master_gap	0.065

Features Decomposition Methodology: To enable stakeholder-specific and engagement-vs-performance analysis, we train a separate HGB classifier on the 60-feature augmented space (53 original features + 7 EAI-derived metrics) and apply SHAP TreeExplainer. Features are categorized into two groups: Engagement features (23 features) and Performance features (30 features). The percentage contribution is computed as:

$$\text{Category}_{\%} = \frac{\sum_{f \in \text{Category}} |\text{SHAP}(f)|}{\text{Total}_{|\text{SHAP}|}} \times 100$$

Engagement vs. Performance Decomposition: The decomposition of features into two main categories, engagement (evaluation counts, participation) versus performance (skill scores, grades), reveals that the engagement features are 56.1% of the predictive signal and the remaining 43.9% are performance features. This feature importance split challenges conventional assumptions that dropout predictions should focus on academic grades, but in our study, active stakeholders' evaluations matter slightly more than what scores they assign. In Table 5, it is presented that the topmost important engagement feature has 75% higher SHAP importance than the most important performance feature. It shows that stakeholder disengagement precedes performance decline, so monitoring evaluation frequency in apprenticeship provides earlier warning signals. It tells that the dropout systems should alert when evaluation rates decline, not just when scores fall. The top 10 features by SHAP importance scores also reveal the dominance of engagement over performance.

EAI Feature Contribution: The seven engagement-derived metrics are computed by the EAI module for SHAP analysis. The importance rankings of these metrics reveal which aspects of stakeholders' asymmetry most strongly predict dropout. The overall EAI Feature Rankings by SHAP importance are (1) Engagement Gap (0.397), the difference between the most and least engaged stakeholders, (2) Apprentice Engagement (0.336), apprentice participation level. (3) Apprentice - Employer Sync (0.235), alignment between apprentice and employer, (4) Employer Engagement (0.171), employer participation level, and (5) EAI (0.159), overall imbalance coefficient. The engagement gap emerges as the most important EAI metric. This suggests that the imbalance magnitude matters more than which specific stakeholder is disengaged. An apprenticeship with one highly engaged stakeholder but two disengaged faces elevates risk regardless of who is engaged. The engagement pattern analysis is presented in Table 6. Students in "apprentice-only" pattern (where only the apprentice evaluates, without employer participation) show 41.7% dropout rate, nearly 5× higher than the minimal baseline (8.5%). This validates the critical importance of employer engagement. The EAI module transforms raw evaluation counts into meaningful

Table 6: Engagement Pattern Analysis

Pattern	Apprentice	Employer	Provider	Dropout Rate	Sample Size
Apprentice-Only	High	None	None	41.7%	72
Employer-Only	None	High	None	23.1%	255
Apprentice-Employer	High	High	None	28.6%	35
Full Triad	High	High	Present	40.0%	5
Minimal	Low	Low	None	8.5%	3144

stakeholder narratives.

7. CONCLUSION AND LIMITATIONS

This paper presents the ESPM approach for dropout predictions in apprenticeship. By modeling the tri-stakeholder dynamic using perception gap features and stakeholder presence mask pattern, ESPM achieves superior performance in terms of F1, Recall, and interpretability compared to nine baseline models. To achieve interpretability, the separate EAI module is used, which enables decomposition of predictive signal by stakeholder and engagement-vs-performance categories. The analysis reveals that engagement features contribute 52.2% and outweigh the performance features 43.9%. The overall findings show that stakeholder disengagement precedes performance decline, challenging conventional grade / performance-focused dropout prediction. Our findings have some implications beyond apprenticeship. First, the dominance of engagement over performance challenges conventional grade-focused learning analytics assumptions for predictions. Second, perception gap features offer a generalizable approach to model expectations misalignment in any feedback-intensive domain (employee reviews or peer assessments, etc.). Third, the tri-stakeholder framework can generalize to other triad contexts (internships or collaborative projects, etc.) as well. The study has some limitations as well, including limited generalizability to other institutes or countries, as our data originates from a single formation (CFA). Another limitation is the sparse coverage of tutor and LEA evaluations, which limits our ability to fully model provider engagement. The dominance of employer features (52.2%) may reflect feature availability bias, as employer evaluations are recorded more often than provider evaluations, which can inflate SHAP importance. The finding that engagement outweighs performance should therefore be interpreted with caution since evaluation frequency is linked to the contract duration and student persistence, where longer contracts generate more records.

ABSTRACT

Course recommender systems (CRSs) play an important role in helping students navigate large-scale online course platforms. However, effective course recommendation remains challenging due to sparse interaction data and the lack of explicit, learning-oriented representations on both the student and course sides. In this paper, we propose SORARec, a Student prOfile and couRse Attribute–aware Recommendation model that leverages large language models (LLMs) to enrich educational recommendations with learning-aware semantic information. Specifically, SORARec employs an LLM to infer structured student profiles and learning-relevant course attributes from historical enrollments and course metadata. These inferred semantics are encoded into dense embeddings and integrated with collaborative representations through a lightweight graph-based fusion mechanism. Unlike approaches that rely on LLMs for direct recommendation, SORARec uses LLMs only in an offline inference stage, preserving efficiency and scalability. Experiments on the real-world MOOC dataset demonstrate that SORARec consistently outperforms baselines under both general and cold-start settings. Ablation studies further confirm the complementary contributions of student profile and course attributes. The results indicate that jointly modeling student profiles and course attributes provides an effective and practical way to improve course recommendation performance in educational scenarios.

1. INTRODUCTION

Massive Open Online Courses (MOOCs) and online learning platforms provide students with unprecedented access to diverse educational resources. However, the rapid growth of course catalogs also makes it increasingly difficult for students to identify courses that align with their backgrounds, interests, and learning goals [14]. Course recommender systems (CRSs) have therefore become a key component of modern educational platforms, supporting students in making informed enrollment decisions [16].

Despite substantial progress, effective course recommendation remains challenging. Unlike general-purpose recommender systems, CRSs must account for learning-oriented factors such as prior knowledge, learning objectives, and course difficulty, in addition to historical preferences. As a result, recommendation quality critically depends on the availability of informative student profiles and course attributes. In practice, however, such information is often missing. Most students enroll in only a small number of courses, leading to severe data sparsity and frequent cold-start situations [4,17,37]. Under these conditions, interaction-based models struggle to infer students' learning needs reliably. Moreover, student characteristics (e.g., background knowledge and difficulty tolerance) are largely latent, while course representations often lack fine-grained semantic and pedagogical attributes, resulting in recommendations that may be misaligned with students' abilities or goals [13, 15, 31].

To alleviate these issues, prior work has incorporated side information, content features, or knowledge graphs into CRSs [3,29]. While effective to some extent, these approaches typically rely on manually curated metadata or domain-specific resources, limiting their scalability. Recently, Large Language Models (LLMs) have demonstrated strong capabilities in semantic understanding and knowledge inference, offering new opportunities for enriching representations in recommender systems. However, existing LLM-based CRSs often augment only one side of the recommendation process [31] or treat LLM outputs as unstructured textual features [30]. In addition, directly using LLMs for recommendation in-

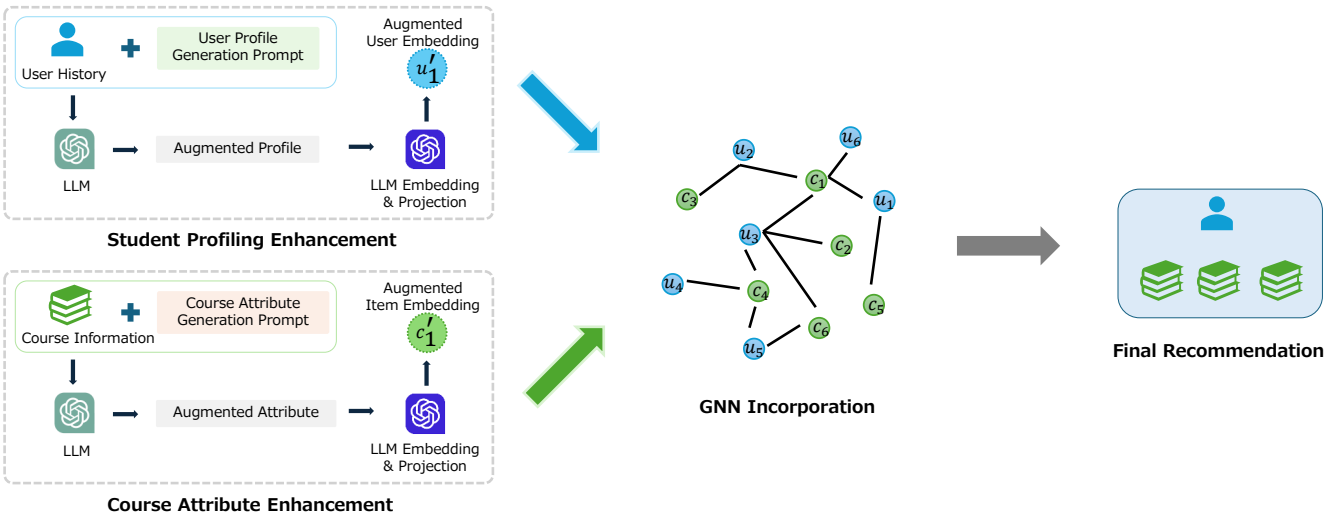

Figure 1: Overview of the proposed SORARec model.

curs high computational cost and does not consistently outperform lightweight neural models. Consequently, how to effectively leverage LLMs to address both representation insufficiency and data sparsity in educational recommendation remains an open question.

In this paper, we propose **SORARec**, a Student prOfile and couRse Attribute–aware course Recommendation model. SORARec employs LLMs to infer structured, learning-oriented student profiles and expressive course attributes from historical interactions and course metadata. These inferred semantics are encoded into dense embeddings and integrated with collaborative representations, complementing interaction data rather than replacing it. Extensive experiments on the real-world MOOC dataset show that SORARec consistently outperforms strong baselines, with particularly notable improvements in sparse and cold-start scenarios. Ablation studies further demonstrate the complementary contributions of student-side and course-side semantic information.

2. RELATED WORK

2.1 Course Recommendation

Course recommendation has been widely studied in educational settings to assist students in navigating large and diverse course catalogs. Early approaches primarily relied on content-based and collaborative filtering methods, which infer student preferences from historical enrollments or course similarity patterns [8, 18–20]. While effective and easy to deploy, these methods are often limited by sparse interaction data and their inability to capture learning-oriented factors.

To address these limitations, later studies introduced sequential, graph-based, and knowledge-aware models to capture course dependencies and student–course interactions [4, 21, 37]. Knowledge-enhanced and explainable CRSs further incorporate structured information such as prerequisite relations or course knowledge graphs to improve recommendation quality and transparency [29, 32]. However, most existing approaches still rely heavily on interaction data or manually curated features, making them vulnerable to data sparsity and cold-start scenarios, and limiting their scalability in real-world educational platforms.

2.2 LLMs for Recommendation and Education

LLMs have demonstrated strong semantic understanding and reasoning capabilities, and have recently been explored in recommender systems to alleviate data sparsity and enrich representations [2, 26]. Existing LLM-based recommendation approaches typically use LLMs to simulate user behaviors, generate auxiliary interactions, or produce preference signals and explanations [7, 25, 27]. While effective, these methods often incur high inference costs or treat LLM outputs as unstructured textual signals.

In parallel, LLMs have been applied in educational contexts for content generation, feedback, and learning support [1, 12, 28]. Recent studies have begun incorporating LLMs into educational recommendation, for example by generating textual recommendations or augmenting student–course representations under sparse conditions [22, 36]. However, the use of LLMs to construct explicit, structured student profiles and learning-relevant course attributes, and to integrate them efficiently into conventional course recommendation models, remains limited. This gap motivates our proposed SORARec framework.

3. THE PROPOSED MODEL

Figure 1 illustrates the overall workflow of SORARec. Given historical student–course interactions and course metadata, SORARec first employs an LLM to infer structured student profiles and learning-relevant course attributes. The inferred profiles and attributes are then encoded into semantic embeddings and aligned with the collaborative embedding space. Next, these semantic representations are propagated over the student–course interaction graph and integrated with interaction-based embeddings to obtain enhanced student and course representations. Finally, SORARec predicts

student–course preferences based on the fused representations and generates personalized course recommendations.

3.1 LLM-based Student Profile and Course Attribute Inference

SORARec employs a LLM as an auxiliary inference module to construct structured student profiles and learning-relevant course attributes. In educational platforms, explicit information about students' learning goals, background knowledge, or difficulty preferences, as well as fine-grained course attributes such as conceptual coverage and pedagogical difficulty, is often unavailable or inconsistently recorded. This information deficiency, combined with sparse interaction data, poses a major challenge for accurate and personalized course recommendations. To address this issue, SORARec leverages the reasoning capability of LLMs to infer missing or implicit attributes from available textual evidence and transforms them into dense semantic representations for downstream recommendation.

Student Profile Inference: For each student u, we collect the historical interaction set $\mathcal{H}_u = \{i_1, i_2, \ldots, i_{|\mathcal{H}_u|}\}$, where each interacted course provides indirect evidence of the student's latent learning characteristics. Then, SORARec prompts an LLM to infer a structured student profile based on the semantic patterns of the courses previously taken.

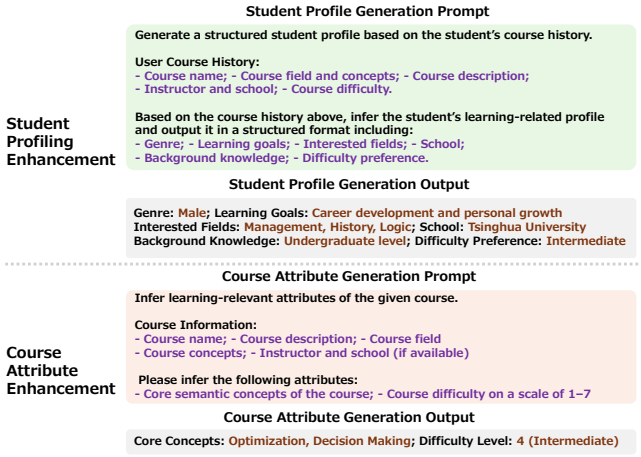

Figure 2: Illustration of the LLM-based semantic inference process in SORARec. The top part shows how student profiles are inferred from historical course enrollments to capture learning goals, background knowledge, and difficulty preferences. The bottom part shows how learning-relevant course attributes, including semantic concepts and difficulty levels, are generated from course metadata.

As illustrated in Fig. 2, the prompt consists of a task description, textual information extracted from the student's enrolled courses (e.g., course titles, topics, and fields), and a strict output schema that enforces a machine-readable format. The LLM is required to infer multiple educationally meaningful facets, such as learning goals, interested fields, background knowledge level, and difficulty preference. Let P_u^{prof} denote the constructed prompt for student u, The inferred student profile is obtained as:

$$A_u = \text{LLM}\left(P_u^{\text{prof}}\right),$$

where A_u is a structured textual description summarizing the student's latent learning characteristics inferred from historical interactions.

Course Attribute Inference: Similarly, for each course i, SORARec employs an LLM to infer learning-relevant course attributes from available course metadata. Course descriptions in online learning platforms are often written in free-form text and vary widely in granularity and quality, which limits their direct use in recommendation models. To obtain more structured and comparable representations, we prompt the LLM with course-specific information, including the course name, description, field, instructor, institution, and existing annotations when available, which is shown in Fig. 2.

The LLM is instructed to infer pedagogically meaningful attributes, with a particular focus on semantic concepts and course difficulty, which are critical for matching courses with students' backgrounds and learning objectives. Let P_i^{attr} denote the prompt constructed for course i. The inferred course attributes are defined as:

$$A_i = \text{LLM}\left(P_i^{\text{attr}}\right),$$

where A_i represents the LLM-generated textual description of the course's semantic and pedagogical characteristics.

Semantic Embedding of Inferred Profiles and Attributes: The inferred student profiles A_u and course attributes A_i are textual or structured outputs that cannot be directly consumed by standard recommendation models. As shown in Fig. 1, SORARec converts these inferred attributes into dense semantic representations using an embedding encoder. Formally, the embedding vectors are computed as:

$$\mathbf{f}_{A,u} = \text{Emb}\left(A_u\right), \quad \mathbf{f}_{A,i} = \text{Emb}\left(A_i\right),$$

where $\text{Emb}(\cdot)$ denotes the embedding function and $\mathbf{f}_{A,u}, \mathbf{f}_{A,i} \in \mathbb{R}^d$ are the resulting student-side and course-side semantic vectors.

By encoding inferred attributes into continuous representations, SORARec enables the integration of high-level educational semantics into the recommendation process while maintaining a lightweight downstream architecture. Notably, the LLM is only used in an offline inference stage, and all subsequent recommendation learning operates on the embedded representations. The utilization of these side information embeddings in the recommendation model is described in the following subsection.

3.2 Side Information Incorporation

After obtaining the LLM-inferred student profiles and course attributes, the key challenge is how to effectively incorporate this information into the course recommendation process. SORARec integrates the inferred student-side and course-side representations with interaction-based learning, enabling the model to jointly exploit collaborative signals

from historical enrollments and the semantic characteristics specific to students and courses.

Let $\mathbf{e}_u \in \mathbb{R}^d$ and $\mathbf{e}_i \in \mathbb{R}^d$ denote the base embeddings of student u and course i, respectively, learned from interaction data. From the LLM-based inference module described in Section 3.2, we obtain semantic representations $\mathbf{f}_{A,u}$ and $\mathbf{f}_{A,i}$, which encode the inferred student profiles and course attributes. The inferred semantic representations are first aligned to the recommender embedding space via a projection operation:

$$\overline{\mathbf{f}_u} = \mathrm{Proj}\left(\mathbf{f}_{A,u}\right), \quad \overline{\mathbf{f}_i} = \mathrm{Proj}\left(\mathbf{f}_{A,i}\right),$$

where $\overline{\mathbf{f}_u}$ and $\overline{\mathbf{f}_i}$ denote the projected semantic embedding obtained by mapping the LLM-inferred representation into the recommender embedding space, $\mathrm{Proj}(\cdot)$ maps the LLM-inferred embeddings from the semantic space to the collaborative embedding space. $\mathrm{Proj}(\cdot)$ is instantiated as a linear transformation, i.e., $\mathrm{Proj}(\mathbf{x}) = \mathbf{x}\mathbf{W}$ with a trainable projection matrix $\mathbf{W}$, and ℓ_2-normalization is applied to mitigate scale discrepancies between heterogeneous representations. Although dimensionally aligned, the projected semantic features do not explicitly encode collaborative structure. To inject interaction-aware context, SORARec further propagates the projected features over the student–course interaction graph $\mathcal{G}$:

$$\tilde{\mathbf{f}}_u = \mathrm{GNN}\left(\overline{\mathbf{f}_u}, \mathcal{G}\right), \quad \tilde{\mathbf{f}}_i = \mathrm{GNN}\left(\overline{\mathbf{f}_i}, \mathcal{G}\right),$$

where $\tilde{\mathbf{f}}_u$ and $\tilde{\mathbf{f}}_i$ represent the context-enhanced semantic embedding after injecting collaborative information through message passing on the interaction graph, and $\mathrm{GNN}(\cdot)$ denotes a message-passing operation that aggregates neighborhood information from $\mathcal{G}$. Finally, the context-enhanced semantic features are incorporated into the base embeddings via a residual-style fusion strategy:

$$\mathbf{h}_u = \mathbf{e}_u + \alpha \cdot \frac{\tilde{\mathbf{f}_u}}{\left\|\tilde{\mathbf{f}_u}\right\|_2}, \quad \mathbf{h}_i = \mathbf{e}_i + \alpha \cdot \frac{\tilde{\mathbf{f}_i}}{\left\|\tilde{\mathbf{f}_i}\right\|_2},$$

where α controls the contribution of semantic side information. The resulting representations $\mathbf{h}_u$ and $\mathbf{h}_i$ jointly capture collaborative signals and learning-relevant semantics, and are subsequently used for preference estimation in the recommendation task.

3.3 Recommendation Objective and Optimization

After incorporating LLM-inferred student profiles and course attributes into the collaborative representations, SORARec performs interaction prediction based on the final student and course embeddings. Given the fused representations $\mathbf{h}_u$ and $\mathbf{h}_i$ obtained in Section 3.3, the preference score between student u and course i is computed via inner product:

$$\hat{y}_{u,i} = \mathbf{h}_u^\top \mathbf{h}_i.$$

Following common practice in implicit-feedback recommendation scenarios, we adopt the Bayesian Personalized Ranking (BPR) [23] loss to optimize the model. The BPR objective encourages the predicted score of an observed interaction to be higher than that of an unobserved one. Specifically, for each student u, we construct training triplets (u, i, j), where i denotes a course that the student has enrolled in, and j denotes a course with no observed interaction. The loss function is defined as:

$$\mathcal{L}_{\mathrm{BPR}} = -\sum_{(u,i,j)\in\mathcal{D}} \log \sigma\left(\hat{y}_{u,i} - \hat{y}_{u,j}\right),$$

where $\sigma(\cdot)$ denotes the sigmoid function and $\mathcal{D}$ is the set of sampled training triplets. The overall objective function includes an ℓ_2 regularization term to prevent overfitting:

$$\mathcal{L} = \mathcal{L}_{\mathrm{BPR}} + \lambda \|\Theta\|_2^2,$$

where Θ represents all trainable parameters in SORARec, including embedding matrices and projection weights, and λ controls the regularization strength. The model is optimized using mini-batch stochastic gradient descent with the Adam [9] optimizer. During inference, SORARec ranks candidate courses for each student based on the predicted scores $\hat{y}_{u,i}$ and recommends the top-K courses with the highest scores.

4. EXPERIMENT SETUP

4.1 Datasets

We evaluate SORARec on a publicly available MOOC dataset, MOOCCube [35], which is a large-scale dataset containing 199,199 users, 706 courses, and 672,853 user-course interaction records. Each course is accompanied by textual metadata, including course titles, detailed descriptions, and manually annotated concepts. Following common practice, we preprocess both datasets by removing users with fewer than five interactions and courses with fewer than ten interactions to ensure data quality and stable evaluation. After preprocessing, the statistics of the resulting dataset are summarized in Table 1.

Table 1: Statistics of the MOOCCube dataset

Dataset	Users	Courses	Interactions	Interactions Density
MOOCCube	33,838	645	263,522	1.2074%

4.2 Metrics

Following prior work on course recommendation [3, 34, 37], we evaluate the recommendation performance using four widely adopted top-K ranking metrics: Precision, Recall, Hit Ratio (HR), and Normalized Discounted Cumulative Gain (NDCG). These metrics assess the quality of the ranked recommendation lists from complementary perspectives, including accuracy, coverage, and ranking quality. For all metrics, higher values indicate better recommendation performance.

4.3 Baselines

To evaluate the effectiveness of SORARec, we compare it with a set of representative baseline methods for course recommendation, covering classical collaborative filtering, factorization-based models, neural recommenders, graph-based approaches, and knowledge-enhanced models. Specifically, we include:

- **Item-based CF** [24], a memory-based collaborative filtering method that recommends courses based on item similarity computed from historical interactions.

Table 2: Performance comparison on the MOOCCube dataset

	K = 5				K = 10			
Model	Precision@5	Recall@5	HR@5	NDCG@5	Precision@10	Recall@10	HR@10	NDCG@10

SORARec	**0.1021**	**0.2874**	**0.4389**	**0.2740**	**0.0724**	**0.4015**	**0.5711**	**0.3274**

- **Matrix Factorization** [10], a matrix factorization model that learns latent representations of students and courses from the interaction matrix.
- **LightFM** [11], a hybrid recommendation model that combines collaborative filtering with side information; we report results under its standard BPR loss.
- **NeuMF** [6], a neural collaborative filtering model that integrates generalized matrix factorization and multilayer perceptrons to capture nonlinear interactions.
- **LightGCN** [5], a graph-based collaborative filtering model that propagates embeddings over the student–course interaction graph using simplified graph convolutions.
- **KEAM** [33], a knowledge-enhanced course recommendation model that incorporates course concepts through an autoencoder-based architecture.

All baseline models are trained and evaluated under the same data splits and evaluation protocol. Hyperparameters are carefully tuned on the validation set, and the best-performing configurations are reported on the test set.

4.4 Training Details

All models were implemented using PyTorch 2.1.2 and trained on a single NVIDIA RTX 4060 Ti GPU. For the MOOCCube dataset, user–course interaction records were randomly split into training, validation, and test sets with a ratio of 8:1:1. For SORARec, LLM-based inference was conducted offline. Student profiles and course attributes were generated using GPT-4o-mini, and the textual outputs were encoded with the text-embedding-3-small model, producing 1536-dimensional semantic embeddings. These embeddings were projected into a 64-dimensional latent space to align with interaction-based representations. All models were evaluated under the same data splits and experimental settings.

5. RESULTS

5.1 Overall Performance Comparison

Table 2 presents the overall performance comparison on the MOOCCube dataset. The main observations are summarized as follows: (1) SORARec consistently achieves the best performance across all evaluation metrics at both $K = 5$ and $K = 10$. This demonstrates the effectiveness of jointly incorporating LLM-inferred student profiles and course attributes into the recommendation process. (2) The improvements indicate that learning-aware semantic representations help SORARec better capture students' latent learning needs and course suitability, which are difficult to infer from sparse interaction data alone. (3) Compared with strong collaborative and knowledge-enhanced baselines, SORARec still yields clear performance gains, highlighting the importance of simultaneously modeling both student-side and course-side information in educational recommendation. (4) Overall, these results confirm that SORARec provides a robust solution for MOOC recommendation by alleviating data sparsity and improving representation quality.

5.2 Ablation Study

To examine the contribution of LLM-inferred student profiles and course attributes in SORARec, we conduct an ablation study by selectively removing semantic information from different sides of the model. Specifically, we compare the following variants:

- **SORARec w/o SP**: This variant removes the student profiles and retains only course attributes.
- **SORARec w/o CA**: This variant removes the course attributes and retains only student profiles.
- **SORARec w/o SP&CA**: This variant removes both student profiles and course attributes, reducing the model to an interaction-only variant.

These comparisons help demonstrate the importance and impact of each component in the overall SORARec model performance. Based on the results presented in Figure 3, we observe that (1) The SORARec model consistently achieves the best performance across all metrics, demonstrating that jointly modeling student profiles and course attributes is more effective than relying on either side alone. (2) Removing either student profiles or course attributes leads to noticeable performance degradation, indicating that both components contribute meaningful and complementary information. (3) The performance drop is slightly larger when removing student profiles than when removing course attributes, suggesting that student-side semantics play a particularly important role in educational recommendation. This aligns with the nature of learning scenarios, where students' background knowledge, learning goals, and difficulty preferences strongly influence course suitability. (4) The interaction-only variant (w/o SP & CA) performs the worst, highlighting the limitation of relying solely on sparse enrollment sig-

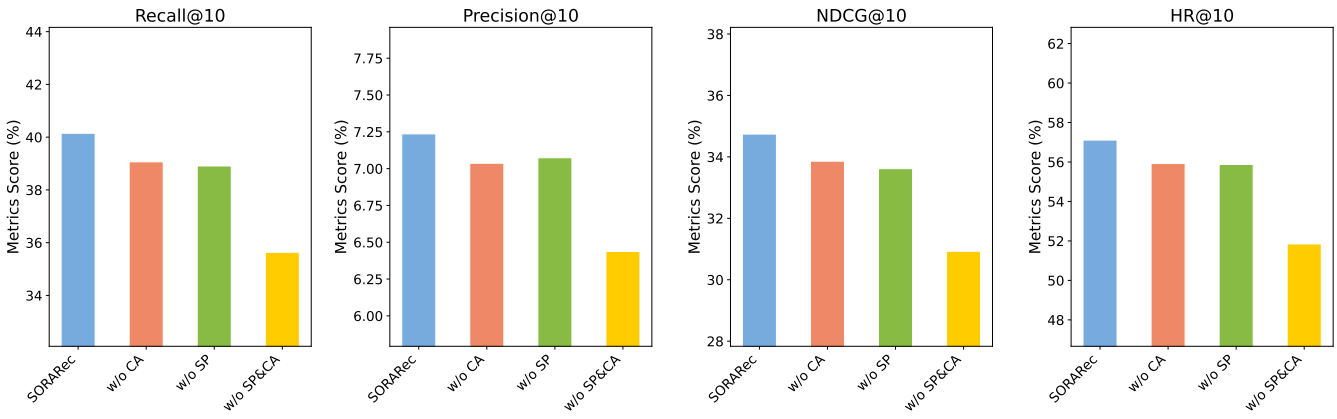

Figure 3: The effectiveness of each component in SORARec.

Table 3: Cold-Start recommendation performance comparison on the MOOCCube dataset

	K = 5		K = 10		K = 15		K = 20

nals. Overall, this ablation study confirms that student profiles and course attributes are both indispensable components of SORARec, and the results further support the importance of explicitly modeling learning-oriented semantics on both sides of the recommendation process.

5.3 Cold-Start Scenario Recommendation

Following the same cold-start setting adopted in prior work [31], we focus on the user cold-start scenario on the MOOCCube dataset by selecting users with no more than five historical interactions. The experimental results are reported in Table 3. The main findings are summarized as follows: (1) SORARec consistently achieves the best performance under cold-start conditions across all Top-K settings. In particular, SORARec outperforms all baselines in both HR and NDCG, demonstrating its strong robustness when user interaction histories are extremely limited. (2) The performance advantage of SORARec becomes more evident as K increases. At $K = 10$, 15, and 20, SORARec shows clear and stable improvements over strong baselines such as LightGCN and KEAM, indicating its superior ability to rank relevant courses higher for cold-start users. (3) Compared with interaction-driven models, SORARec benefits from LLM-inferred student profiles and course attributes, which provide learning-aware semantic signals beyond sparse behavioral data. These semantic representations effectively compensate for missing interactions and enable more reliable preference estimation in cold-start scenarios. (4) Overall, the results confirm that SORARec is particularly well-suited for user cold-start recommendation. By jointly leveraging collaborative information and inferred educational semantics, SORARec substantially improves recommendation performance under sparse data conditions. While all models benefit from sufficient interaction histories in the general setting (Section 5.1), cold-start evaluation provides a clearer view of how effectively learning-aware semantic representations can compensate for missing behavioral signals.

6. CONCLUSIONS

In this paper, we proposed SORARec and explored the use of large language models to enhance course recommendation by enriching both the student side and the course side with inferred semantic information. Specifically, we leveraged LLMs to generate structured student profiles from historical learning behaviors and to extract learning-relevant attributes from course descriptions, and incorporated these signals into the recommendation process. Experimental results show that augmenting student and course representations with LLM-inferred information leads to consistent performance improvements over baseline methods, particularly in sparse interaction settings. Rather than treating LLMs as end-to-end recommenders, our findings suggest that their strength in this context lies in supporting the understanding and modeling of students and courses, thereby complementing data-driven recommendation models.

However, this work has several limitations pointing to directions for future research. First, the current framework focuses on augmenting student profiles and course attributes, but does not explicitly address interaction-level completion.

A natural extension is to allow LLMs to predict potential liked and disliked courses by jointly considering student profiles and course attributes, thereby enriching the interaction space under sparse or cold-start conditions. Second, LLM-generated content is inherently subject to hallucination and uncertainty, which may introduce noise into the recommendation process. Future work will explore mechanisms to mitigate these effects, such as constrained generation, consistency checking across multiple prompts, and verification against existing course information. Finally, our evaluation relies on offline recommendation metrics, which cannot fully reflect the educational validity of the generated profiles and recommendations. We therefore plan to conduct user studies involving students and instructors, asking them to assess the accuracy, plausibility, and usefulness of the inferred student profiles, course attributes, and predicted preferences. Such human-centered evaluation will be crucial for understanding the practical value and limitations of LLM-augmented course recommendation in real educational settings.

Cross-Context Urgency Detection in MOOC Forums

Shreya Singhal
Indian Institute of Technology, Madras
singhalshreya201@gmail.com

ABSTRACT

Urgency detection in online course forums aims to identify posts that need a timely instructor response. A key challenge is cross-context generalization: models trained on Western MOOC forums may not work well in non-Western settings where help-seeking norms and urgency cues differ. This study trains an urgency model on a Western MOOC dataset and evaluates it on a second Western benchmark and a new Indian dataset of 305 forum posts (two-coder weighted κ=0.7308). Using a 3-level actionability mapping (non-actionable, TF-actionable, instructor-actionable), the Western-trained model performs worse in the Indian setting than in the Western benchmark (Stanford ρ=0.381 vs. Indian ρ=0.292) and retrieves few instructor-actionable posts under limited review (Indian recall@50=0.194). Class balancing yields a small gain (Indian ρ=0.306), while adding a small amount of labeled Indian training data improves performance on a held-out Indian test split (ρ=0.401; recall@50=0.511) without materially changing Western benchmark dataset results.

Keywords

urgency detection, discussion forums, MOOCs, cross-context generalization, class imbalance

1. INTRODUCTION

Discussion forums are a primary channel for learner support in MOOCs and other large-scale online courses. Learners use them to ask questions, report technical issues, and seek clarification, but at scale they also create a recurring bottleneck where teaching teams must decide what to respond to first. Some posts describe time-sensitive blockers (e.g., access problems, deadline constraints, exam logistics, or escalating confusion) where delayed help can meaningfully affect learning progress. This motivates urgency detection: prioritizing posts that need faster staff attention under limited capacity.

Educational data mining has increasingly treated forum discourse as actionable data, enabling instructor-facing support tools that go beyond participation summaries. Prior work has studied closely related prioritization problems such as predicting when an instructor is likely to intervene in a discussion thread, using a combination of language cues and discussion structure [5,6].

A key concern is generalization. Urgency is shaped not only by what is being asked, but also by how learners express time pressure and needs which are patterns that can vary across platforms, course designs, and broader communication norms. Most models are built and validated within relatively narrow settings, which makes it unclear whether they remain reliable when deployed in new contexts. This matters because the highest-urgency, instructor-actionable cases are often the most operationally important to detect yet may be sparse in training data.

This paper frames urgency detection explicitly as a cross-context robustness problem. It extends the work of Švábenský et al. [12] and evaluates whether urgency models trained in a Western MOOC context transfer to (i) a second Western benchmark dataset and (ii) a non-Western MOOC forum context, and it examines two pragmatic strategies for improving reliability in the new setting: incorporating a small amount of labeled target-context data and addressing class imbalance for instructor-actionable posts.

We address the following research questions:

RQ1: How well do urgency detection models trained on Western MOOC forum data generalize to a non-Western MOOC forum context?

RQ2: How does class imbalance affect model performance under cross-context transfer, especially for instructor-actionable posts?

RQ3: To what extent does adding a small amount of labeled non-Western data to the training data improve model performance?

2. RELATED WORK

2.1 Urgency detection in MOOC discussion forums

Urgency detection is typically framed as predicting which learner posts need timely staff attention in large-scale online courses. Much of the early work used the Stanford MOOCPosts benchmark [1] and simplified the 7-point urgency construct into a binary "urgent vs. not urgent" decision, highlighting that truly urgent cases are rare and easy to miss in large volumes of routine posts [2]. This line of work positions urgency as an instructor-support problem: models are valuable only insofar as they help teaching teams prioritize limited response capacity.

More recent work has emphasized that strong performance on a single benchmark can overstate real-world usefulness when course topics, learner populations, or platform norms change. Švábenský et al. [12] made this concern explicit by evaluating urgency prediction under dataset shift and by treating urgency as an ordered construct rather than only a binary cutoff, clarifying that generalization is a central challenge for deployment.

Urgency detection is also related to the broader problem of predicting instructor intervention in MOOC discussion forums. Chaturvedi et al. [6] studied whether instructor intervention could be predicted from MOOC forum activity and showed that intervention prediction depends on signals beyond the post text itself, including course and discussion context. Chandrasekaran et al. [5] similarly examined instructor intervention across MOOC forum threads and highlighted the role of forum structure and

instructional context in determining when staff responses are needed. These studies show that actionability may not be a property of post text alone. Whether a post requires a teaching assistant or instructor response can depend on the course design, available support channels, learner expectations, and local instructional practices.

2.2 From feature engineering to embedding-based models

Modeling approaches for urgency detection have broadly followed trends in NLP for educational text: from lexical feature baselines to representation learning with neural embeddings. For example, Guo et al. [7] proposed a deep learning approach for identifying urgent posts in MOOC forums, and Khodeir [8] used BERT-based text representations with a recurrent architecture for urgency classification. These approaches aim to capture meaning beyond surface word counts and to be more tolerant of noisy forum writing.

A parallel strand incorporates additional signals beyond raw text, such as post metadata or learner/context cues, motivated by the idea that urgency is not only "what is said" but also "when and how it is asked." Alrajhi et al. [3] combined textual and numerical features for predicting urgent responses, and Yu et al. [13] explored Bayesian deep learning to estimate instructor intervention need with uncertainty, reflecting interest in decision support settings where false negatives on high-priority posts are costly.

2.3 Generalizability, class imbalance, and evaluation gaps

Two persistent issues recur across the literature: (i) limited cross-context generalization and (ii) severe class imbalance. Urgent posts are typically a small minority in Western MOOC benchmarks [2], which can encourage models that achieve good average error while still failing on the cases that matter most operationally. This motivates both evaluation protocols that stress robustness under shift [12] and training strategies that explicitly address imbalance. For example, Alrajhi et al. [4] focus on urgency detection under imbalance and study methods intended to improve detection of the minority class.

Finally, there is increasing recognition that "stronger" NLP architectures do not automatically translate into better educational utility without careful evaluation. Work on broader educational forum-post classification emphasizes systematic comparisons and robustness-focused metrics rather than assuming newer models dominate by default [9,10]. This motivates evaluations that reflect instructor-facing workflows (e.g., whether high-priority posts appear near the top of a ranked list), not only aggregate error.

Building directly on the cross-dataset framing in Švábenský et al. [12], this paper targets the remaining gap between benchmark performance and deployment-relevant reliability under context shift by evaluating transfer to a non-Western forum setting and by testing pragmatic strategies that can be applied when only limited target-context labels are available.

3. RESEARCH METHODS

This section describes the data and procedures used to train and evaluate predictive models of discussion-forum post urgency. This paper's methodology adapts the full pipeline from Towards Generalizable Detection of Urgency of Discussion Forum Posts [12] including the 7-point ordinal urgency construct, coder protocol, lightweight NLP preprocessing, and cross-dataset generalizability evaluation. It then extends it in two ways that align with the motivation and gaps: (1) evaluation on an additional non-Western MOOC forum dataset labeled on the same scale, and (2) two deployment-relevant strategies intended to improve robustness under context shift: low-resource target-domain adaptation and class-imbalance mitigation.

3.1 Data Collection and Properties

This paper reuses the datasets used by Švábenský et al. [12]: (1) UPenn MOOC forum-post dataset (used here as the main training dataset), and (2) the Stanford MOOCPosts dataset (used here as a separate Western test dataset). In addition, this paper introduces a new Indian MOOC forum-post dataset to test how well models trained on Western MOOC posts work in a different context.

UPenn MOOC forum posts (Western training dataset). Following Švábenský et al. (2023), the training data consists of forum posts from nine UPenn MOOCs offered between 2012–2015. The original dataset construction sampled 500 posts per course and removed posts that were non-English or contained only symbols, only math, or only links, resulting in 3,503 posts from 2,882 students. Each post includes a student ID, timestamp, and post text. Typos and grammatical errors were kept as written.

Stanford MOOCPosts (Western test dataset). Performance is evaluated on the Stanford MOOCPosts dataset, a benchmark dataset introduced by Agrawal and Paepcke [1]. It contains 29,604 anonymized discussion-forum posts collected from 11 Stanford MOOCs. The 11 courses are grouped into three broad areas (Humanities/Sciences, Medicine, and Education) with approximately 10,000 posts per area. This benchmark is used here as a separate Western test dataset, consistent with its use for generalization testing in Švábenský et al. [12].

Indian MOOC forum posts (Non-Western dataset). A new dataset of 305 forum posts was collected from the Discourse forum of an online MOOC degree program in India. Posts were scraped from discussions occurring between 2024-2025 and were collected with the following fields: post ID, title, timestamp, and course ID. The raw text was cleaned by removing HTML and excluding posts that were not in English. The final sample includes posts drawn from four data science–related courses (Programming in Python; Statistics for Data Science; Business Data Management; Strategies for Professional Growth), with roughly 75 posts sampled per course. This dataset is used to evaluate performance in a new setting and to support later experiments that add a small amount of Indian training data.

Table 1 summarizes the three datasets, including their sources, number of courses, number of posts, and collection period.

Table 1. Summary of datasets used in this study

Dataset	Source	Courses	Posts	Time span
UPenn MOOC forums	Švábenský et al. [12]	9	3,503	2012–2015
Stanford MOOCPosts	Agrawal & Paepcke [1]	11	29,604	2013-2014
Indian MOOCPosts	Discourse forum of a MOOC degree program in India	4	305	2024–2025

3.2 Data Anonymization

The UPenn and Stanford datasets were used in their already de-identified forms [12], without additional anonymization. For the Indian dataset, personally identifying information was redacted during scraping using the GPT-4-0613 model-based procedure in Singhal et al. [11]. Each post was processed individually using the same prompt structure, which instructs the model to redact specific categories of PII and preserve the original text formatting. It was further checked during the labeling phase by two coders.

3.3 Data Labeling

This study adopts the urgency construct and labeling protocol used in [12] and then refines it. Urgency is defined as the degree to which an instructor response is needed quickly, expressed on a 7-point ordinal scale (1 = not urgent at all, 7 = extremely urgent) [12]. The same scale descriptions are used to ensure direct comparability across datasets and settings. Ordinal scores correspond to the following anchors:

1: No reason to read the post

2: Not actionable, read if time

3: Not actionable, may be interesting

4: Neutral, respond if spare time

5: Somewhat urgent, good idea to reply; a teaching assistant might suffice

6: Very urgent, good idea for the instructor to reply

7: Extremely urgent, instructor definitely needs to reply

For the Indian dataset, posts are labeled using the same scale and training structure as [12]: coders complete structured practice on held-out examples, then label posts independently. Inter-rater reliability is assessed using weighted Cohen's κ (linear weights), consistent with the ordinal nature of the scale [12]. In this study, the Indian dataset was labeled by 2 coders and achieved $\kappa = 0.7308$. Disagreements were resolved via adjudication (discussion to consensus) to produce a single final label per post.

After the first round of labeling, it was observed that the urgency labels are imbalanced in both UPenn and Stanford datasets, with substantially more posts at the lower and middle urgency levels and comparatively fewer posts at the highest urgency levels (6–7). This skew is important because the rare high-urgency cases are the most instructionally actionable, yet they are underrepresented in the data. On the other hand, the Indian dataset contained a much higher proportion of high-urgency posts.

To align the prediction task with an instructor-facing triage workflow and reduce sparsity at the upper end of the urgency scale, the original 7-point urgency annotations were mapped into three actionability categories, as shown in Table 2. The 7-point scale was used for annotation and comparability with prior work, while the 3-level actionability labels were used for all model training and evaluation reported in this paper. This mapping preserves the key operational distinction in the original scale: whether a post is non-actionable, teaching-assistant-actionable, or instructor-actionable. The resulting 3-level scheme provides more stable categories for modeling and evaluation under severe class imbalance, and all reported metrics should therefore be interpreted on this 1–3 actionability scale rather than on the original 1–7 urgency scale.

Table 2. Distribution of actionability labels derived from the 7-point urgency scale.

Label	Meaning	UPenn (N=3,503)	Stanford (N=29,604)	Indian (N=305)
1	Non-actionable (1–3)	2,830 (80.8%)	21,806 (73.7%)	78 (25.6%)
2	TF-actionable (4–5)	623 (17.8%)	5,313 (17.9%)	134 (43.9%)
3	Instructor-actionable (6–7)	50 (1.4%)	2,485 (8.4%)	93 (30.5%)

3.4 Data Automated Pre-Processing

A lightweight preprocessing pipeline matching Švábenský et al. [12] was used to reduce superficial variation while retaining the linguistic cues that may signal urgency. The following steps were applied in order:

- Convert text to lowercase.
- Replace non-alphanumeric characters with spaces (preserving letters and digits).
- Normalize whitespace (remove duplicates).
- Remove common English stopwords.
- Apply stemming to reduce inflected forms to a shared root.

Spelling and grammar correction were not performed intentionally, as these artifacts may differ systematically across contexts.

3.5 Model Training and Cross-Validation

This section describes the shared model-training and validation procedure used to answer RQ1 (cross-context generalization), RQ2 (class-imbalance mitigation), and RQ3 (low-resource target-domain adaptation). Following the design principle established in Sections 3.1–3.4, the modeling pipeline holds the base learner and representation fixed to the strongest-performing configuration in [12] and varies only the training procedure for imbalance handling (RQ2) and training data composition (RQ3).

3.5.1 Model and feature representation

Urgency is modeled using support vector regression (SVR) with an RBF kernel, trained on Universal Sentence Encoder v4 (USE) embeddings of post text. SVR hyperparameters are left at default settings, consistent with the baseline configuration in [12]. Each post is embedded using USE v4 (TensorFlow Hub) to obtain a fixed-length dense representation, which is used directly as the input feature vector for SVR. The purpose of this study is not to establish a new state-of-the-art model for urgency detection, but to test cross-context robustness under a controlled and comparable modeling pipeline. For this reason, the USE + SVR configuration is held fixed across experiments. This design makes it possible to attribute changes in performance primarily to evaluation context, class-imbalance mitigation, and target-context supervision rather than to changes in model architecture.

3.5.2 Cross-validation protocol (student-level grouping)

Model selection and in-domain validation use 10-fold student-level cross-validation implemented with GroupKFold, where the grouping variable is the student identifier. This ensures that all

posts from a given student occur in a single fold, preventing leakage across train and validation splits. For all cross-validation results, metrics are computed on the held-out fold and then averaged across folds.

For any setting in which training data combines UPenn and Indian examples (RQ3), student identifiers from the Indian dataset are offset by a large constant prior to grouping to avoid accidental ID collisions across datasets.

3.5.3 Training and evaluation settings by research question

RQ1: Cross-context generalization (Western → non-Western).

For RQ1, the model is trained using the full UPenn training dataset. Ten-fold student-level cross-validation is computed on UPenn. After cross-validation, the model is refit on the full UPenn training set and evaluated separately on the two external datasets: Stanford MOOCPosts (Western benchmark) and the Indian dataset (non-Western setting). External evaluations are performed without combining the two test datasets.

RQ2: Class-imbalance mitigation (in-fold SMOTE).

RQ2 evaluates whether mitigating label imbalance improves performance while holding the learner and representation fixed. In this condition, SMOTE oversampling is applied in the USE embedding space to rebalance the refined 3-level labels (Section 3.3). Oversampling is performed only on the training split within each cross-validation fold; validation folds remain untouched. Concretely, within each GroupKFold split, SMOTE is applied to the training fold to generate synthetic minority examples, SVR is trained on the resampled training fold, and evaluation is performed on the original validation fold.

Because minority-class counts vary across folds, the SMOTE neighborhood parameter is set adaptively per fold. If any class has fewer than two examples in the training fold, SMOTE is not well-defined; in that case, oversampling is skipped for that fold and SVR is trained on the unresampled training fold.

After cross-validation, a final RQ2 model for external testing is trained by applying SMOTE once to the full UPenn training set (again in embedding space) and fitting SVR on the resulting oversampled set. This model is then evaluated separately on Stanford MOOCPosts and the Indian dataset. No resampling is applied to any test set.

RQ3: Low-resource target-domain adaptation.

For RQ3, the goal is to test whether adding a small amount of labeled target-domain data improves performance in the Indian setting. The Indian dataset is split 50/50 into an Indian-train subset and an Indian-test subset using a stratified split over the refined 3-level urgency labels (Section 3.3) to preserve label proportions across the two halves. The training pool is then formed by concatenating all UPenn training examples with the Indian-train subset. Ten-fold student-level GroupKFold is run on this combined training pool. After cross-validation, the model is refit on the full combined training pool and evaluated separately on Stanford MOOCPosts and the held-out Indian-test subset.

3.6 Model Generalizability Evaluation

Model generalizability is evaluated by measuring performance under dataset shift and low-resource target-data inclusion, aligned with RQ1–RQ3. All reported results are computed on held-out data only (validation folds in cross-validation and external test sets). No resampling or rebalancing is applied to any validation or test split.

Performance is summarized using root mean squared error (RMSE) and Spearman's rank correlation (ρ) between predicted urgency and gold labels. RMSE captures average prediction error magnitude, while Spearman's ρ measures ordinal agreement and is appropriate for urgency as an ordered construct. Predictions are treated as continuous regression outputs and are not rounded prior to computing either metric.

Since the intended use case is prioritization under limited staff time, evaluation additionally includes top-k precision and recall for the highest actionability level. For each evaluation split, posts are ranked by predicted urgency (descending). "Instructor-actionable" corresponds to Level 3 in the refined label scheme (Section 3.3). Precision@k is the fraction of the top-k ranked posts that are instructor-actionable and Recall@k is the fraction of all instructor-actionable posts that appear in the top-k. Unless otherwise noted, results report k = 10 and 50 to reflect small and moderate review budgets.

For training settings that use the UPenn dataset, in-domain performance is estimated via 10-fold student-level cross-validation (Section 3.5). RMSE, Spearman's ρ, and top-k precision/recall are computed on each held-out fold and then averaged across folds.

Generalizability across contexts is assessed through external evaluation on Stanford MOOCPosts and the Indian dataset. For RQ1, a model trained on UPenn is evaluated separately on Stanford and on the full Indian dataset. For RQ2, the class-balancing condition (SMOTE applied during training, Section 3.5) is evaluated separately on Stanford and on the full Indian dataset. For RQ3, the low-resource target-data condition is evaluated on Stanford and on the held-out Indian-test split (with the Indian 50/50 split defined in Section 3.5). Across conditions, results are reported for (i) UPenn cross-validation (when applicable), (ii) Stanford test performance, and (iii) Indian test performance, using RMSE, Spearman's ρ, and the top-k instructor-actionable precision/recall metrics defined above.

4. RESULTS AND DISCUSSION

This section reports findings for RQ1–RQ3 using the refined 3-level actionability labels from Section 3.3 (1 = non-actionable, 2 = TF-actionable, 3 = instructor-actionable). Overall predictive performance is summarized with RMSE and Spearman's ρ. To connect performance to an instructor-facing workflow, triage utility is summarized using precision@10 (concentration of instructor-actionable posts in the top 10) and recall@50 (coverage of instructor-actionable posts when reviewing the top 50).

Table 3. Predictive performance and triage utility across research questions (instructor-actionable = label 3)

RQ	Training setup	CV (RMSE / ρ)	Stanford (RMSE / ρ)	Indian (RMSE / ρ)	Indian p@10	Indian r@50
RQ 1	UPenn only	**0.3832 / 0.4465**	**0.5895 / 0.3812**	**1.0061 / 0.2918**	0.40	0.194
RQ 2	UPenn + in-fold SMOTE	**0.3892 / 0.4345**	**0.5900 / 0.3719**	**0.9822 / 0.3064**	0.60	0.237

RQ	Training setup	CV (RMSE / ρ)	Stanford (RMSE / ρ)	Indian (RMSE / ρ)	Indian p@10	Indian r@50
RQ3	UPenn + Indian-train (50%)	**0.4028 / 0.4891**	**0.5888 / 0.3805**	**0.6932 / 0.4012**	0.600	0.511

All results are computed using the refined 3-level actionability labels, not the original 7-point annotation scale. SVR predictions are continuous and are not rounded before computing RMSE or Spearman's ρ. Triage metrics are computed for label 3 (instructor-actionable) only. The Indian column is evaluated on the full Indian dataset for RQ1–RQ2 (N = 305; instructor-actionable = 93) and on the held-out Indian-test split for RQ3 (N = 153; instructor-actionable = 47).

4.1 RQ1: Cross-context generalization

The RQ1 results show that the UPenn-trained model transfers better to the Stanford benchmark than to the Indian dataset. On Stanford, the model achieves RMSE = 0.5895 and Spearman's ρ = 0.3812. On the Indian dataset, performance drops to RMSE = 1.0061 and Spearman's ρ = 0.2918. The triage-oriented results show a similar pattern: Indian precision@10 is 0.40 and recall@50 is 0.194, meaning that the model retrieves only a small share of instructor-actionable posts within a limited review budget.

One likely reason for this drop is the difference in actionability distributions. In the UPenn training data, instructor-actionable posts are rare, so the model learns urgency patterns from a setting where high-actionability cases are uncommon. In the Indian dataset, instructor-actionable posts are much more frequent and may also be expressed through different linguistic and pragmatic cues. As a result, the model is being asked to prioritize a different mix of learner needs than the one represented in its training data. This suggests a context-shift explanation rather than a purely "harder dataset" explanation.

These results should be interpreted as evidence of cross-context sensitivity, not as evidence of culture alone. The Indian dataset differs from the Western benchmarks along several dimensions, including platform, institutional setting, course design, learner population, and actionability distribution. The lower transfer performance suggests that a model trained in one benchmark setting may not fully capture the local cues that define instructor actionability in another.

4.2 RQ2: Class-imbalance mitigation

The RQ2 results show that SMOTE produces a small but limited improvement in the Indian setting. Compared with the UPenn-only model, the SMOTE model lowers Indian RMSE from 1.0061 to 0.9822 and increases Spearman's ρ from 0.2918 to 0.3064. The triage-oriented metrics also improve as precision@10 rises from 0.40 to 0.60 and recall@50 increases from 0.194 to 0.237. These results suggest that class rebalancing helps the model move more instructor-actionable posts toward the top of the ranked list, which is useful for an instructor-facing triage workflow.

However, the improvement is limited. The SMOTE model still performs substantially worse on the Indian dataset than on the Stanford benchmark, so class imbalance cannot be the whole explanation for the transfer gap. SMOTE can rebalance the source training distribution, but it cannot introduce target-context cues that are missing from the UPenn data, such as how learners in the Indian setting signal urgency, what kinds of requests are common, or how problems are framed in that course and platform environment. In other words, increasing exposure to rare instructor-actionable cases helps, but it does not necessarily solve cross-context generalization.

This distinction matters because urgency detection is ultimately a triage task. A false positive may ask staff to review a lower-priority post, but a false negative may leave an instructor-actionable issue unresolved. The increase in precision@10 is therefore encouraging because it means the top of the ranked list contains more instructor-actionable posts. At the same time, recall@50 remains low, meaning that many instructor-actionable posts are still not retrieved within a realistic review budget. This is why top-k precision and recall are important alongside RMSE and Spearman's ρ, because aggregate score accuracy can miss whether the model is helping staff find the posts that most need timely attention.

4.3 RQ3: Low-resource target-domain adaptation.

The RQ3 results show that adding a small amount of labeled Indian data produces the strongest improvement in the Indian setting. Compared with the UPenn-only model, the UPenn + Indian-train model lowers Indian RMSE from 1.0061 to 0.6932 and increases Spearman's ρ from 0.2918 to 0.4012. The triage metrics also improve substantially as precision@10 rises from 0.40 to 0.60 and recall@50 increases from 0.194 to 0.511. This means that the adapted model retrieves more than half of the instructor-actionable posts in the held-out Indian test set within the top 50 ranked posts.

These gains suggest that even limited target-context supervision can help the model learn local patterns of actionability. Adding Indian training examples may help the model distinguish posts that can be handled by a teaching assistant from those that require instructor attention in this specific course and platform environment. This is especially important because the Indian dataset has a much larger share of instructor-actionable posts than the UPenn training data. The target-context examples therefore help recalibrate what high actionability looks like in the new setting.

At the same time, this result should be interpreted carefully. The RQ3 Indian result is evaluated on the held-out Indian test split rather than the full Indian dataset, so it is not directly identical to the RQ1 and RQ2 Indian evaluations. However, the direction and size of the improvement are still practically meaningful. The main implication is that local calibration may be more useful than source-only rebalancing when deploying urgency models in new educational contexts. The result does not imply that every institution needs a large labeled dataset before deployment. Rather, it suggests that even modest target-context supervision can improve triage utility when the target setting differs from the source training context.

4.4 Comparison with Existing Work

The results extend prior work on MOOC forum urgency detection in a more specific way than simply testing another dataset. Almatrafi et al. [2] framed urgent MOOC posts as a "needle in a haystack" problem: high-priority posts are rare but missing them can matter for learner support. That framing fits the UPenn training data used in this study, where instructor-actionable posts are extremely sparse. However, the Indian dataset complicates this assumption because instructor-actionable posts are not rare in the same way. This difference matters because a model trained in a source context where high-actionability cases are unusual may be

poorly calibrated for a target context where such cases are much more common. Thus, the present findings suggest that urgency detection is not only a minority-class detection problem; it is also a distribution-shift problem.

This distinction also sharpens the contribution relative to Švábenský et al. [12]. Their work showed that urgency prediction should be evaluated under dataset shift and treated as an ordered construct rather than only as a binary urgent/not-urgent classification task. The present study follows that logic by retaining a comparable urgency construct and modeling pipeline but tests a different kind of shift. The UPenn-to-Stanford comparison evaluates transfer between Western MOOC benchmarks, while the UPenn-to-Indian comparison evaluates transfer to a setting that differs in platform, institutional context, learner population, and actionability distribution. The larger degradation on the Indian dataset shows that benchmark-to-benchmark generalization may understate the difficulty of deploying urgency models in substantially different educational settings.

The findings also connect urgency detection to the broader literature on instructor intervention. Chaturvedi et al. [6] modeled instructor intervention in MOOC forums using signals from forum activity and course context, and Chandrasekaran et al. [5] examined intervention prediction across forum threads, highlighting the role of forum structure and instructional context. The present results support this broader interpretation of actionability. A post's need for instructor attention is not determined by its wording alone; it also depends on the course design, available support structures, and local expectations about who should respond. This helps explain why a model can perform reasonably on Stanford while degrading on the Indian dataset, even though all datasets contain MOOC forum posts. The relevant shift is not simply geographic or cultural, but instructional and operational.

The SMOTE results further qualify prior work on imbalance in urgency detection. Alrajhi et al. [4] focus on class imbalance as a central challenge for automatic urgency detection. The present results support the importance of that issue, since SMOTE improves the concentration of instructor-actionable posts near the top of the ranked list. At the same time, the improvement is limited: rebalancing the UPenn training data does not make the model transfer well to the Indian setting. This suggests that imbalance mitigation can improve exposure to rare source-context labels but cannot replace target-context information when the cues, frequency, or meaning of actionability differ across settings.

Finally, the results align with broader educational forum classification work by Sha et al. [9,10], who caution against evaluating educational text classifiers only through narrow model-performance comparisons. The present study makes a similar point from a deployment perspective. The main issue is not whether USE + SVR is the best possible architecture, but whether a model that appears useful under one evaluation context remains useful when the instructional context changes. By holding the model fixed, this study shows that changes in training composition and target context can substantially affect both ordinal prediction quality and triage utility. The contribution is therefore not a new classifier, but evidence that urgency detection systems need target-context validation, actionability-aware evaluation, and metrics that reflect how teaching teams review and prioritize forum posts.

4.5 Opportunities for Future Work

A first direction is to strengthen the generalization claims through broader and more realistic validation. This includes evaluating a fuller transfer matrix across UPenn, Stanford, Indian, and additional datasets to separate source-dataset, target-dataset, platform, and regional/contextual effects. It also includes collecting additional target-context datasets across multiple institutions, disciplines, and platforms, including potentially multilingual settings. Because the Indian dataset in this study is small and concentrated in data science-related courses, broader validation is needed before making stronger claims about non-Western MOOC contexts more generally. Future work should also test sensitivity to different sampling and split strategies and evaluate whether adaptation learned in one target context transfers to another.

In parallel, the triage framing can be made more decision-relevant by aligning k with actual staffing constraints, reporting class-wise false positives and false negatives, assigning higher costs to missed instructor-actionable posts, and evaluating the stability of actionability thresholds across contexts via calibration. A second direction is to move from "regression that is evaluated as triage" toward methods that are explicitly optimized for triage. This includes learning-to-rank or cost-sensitive objectives that prioritize instructor-actionable retrieval, alternatives to SMOTE that avoid synthetic embedding points, and richer adaptation strategies that leverage unlabeled target posts. Future work should also compare additional model families, including ordinal regression, random forests, transformer-based classifiers, and uncertainty-aware models. Finally, error analyses that categorize missed instructor-actionable posts by pedagogical function, and small instructor-in-the-loop studies that measure time saved and perceived usefulness, would connect offline metrics to instructional outcomes and clarify which improvements matter most in practice.

5. CONCLUSION

This paper extends prior work on MOOC forum-post urgency prediction by evaluating cross-context generalization in a setting that includes both Western benchmarks and a new non-Western forum dataset, while retaining a comparable modeling pipeline to isolate the effect of context shift. The results show that models trained on Western MOOC posts can generalize reasonably to another Western benchmark but degrade substantially when transferred to the Indian context, particularly on the instructor-actionable cases that are most important for instructional triage. Because the Indian dataset differs from the Western benchmarks along multiple dimensions, these findings should be interpreted as evidence of cross-context sensitivity rather than as proof of a purely cultural effect. Incorporating triage-oriented evaluation further clarifies this gap by highlighting how differences in ranking behavior under constrained review budgets can matter even when global performance metrics appear similar.

Across the robustness strategies examined, low-resource target-domain adaptation by adding a small amount of labeled target-context data provides the largest and most operationally meaningful improvements, outperforming class-imbalance mitigation via oversampling. Taken together, these findings suggest that reliable urgency triage across diverse educational contexts will likely require at least modest target-domain supervision and evaluation that reflects instructor workflows, rather than relying on source-only training and global fit metrics alone. For EDM systems intended to guide instructor attention, benchmark performance should therefore be accompanied by target-context validation, triage-oriented metrics, and explicit attention to missed instructor-actionable posts. Future work should broaden validation across additional contexts and move toward triage-optimized training and calibration so that actionability decisions remain stable and useful when deployed.

6. ACKNOWLEDGMENTS

The author thanks Švábenský et al. for making the UPenn MOOC forum-post dataset available for research use and for providing the methodological foundation for this study. The author also thanks the IIT Madras BS in Data Science and Applications program for granting permission to use the Indian forum data. The author is grateful to Hyejoo Yun and Jaidev Deshpande for their contributions to the initial conceptualization of the project.

ChatGPT was used for editing and language refinement during preparation of this paper; all research design, analysis, interpretation, and final content decisions remain the responsibility of the author.

ABSTRACT

Item response theory (IRT) is a modeling framework that defines the probability of a correct response through an item characteristic curve (ICC), which is a function of examinee ability and item characteristics. However, since IRT-based estimation typically requires large-scale pretesting with many examinees, question difficulty estimation from text (QDET) has been proposed to estimate item characteristics directly from text. While prior QDET models designed the objective function to align each parameter separately, we instead focus on the shape similarity of ICCs. In addition, we introduce an approach that leverages not only labeled IRT data but also auxiliary information available on real-world e-learning platforms. This allows us to learn from both items with estimated parameters and items whose parameters have not been estimated, using difficulty ordering information such as curriculum level.

We propose two loss terms that exploit both labeled and unlabeled items while reflecting the relationship between item parameters and the ICC. First, since the ICC can be approximated by the cumulative distribution function of a normal distribution, the similarity between ICCs can be formulated as the similarity between normal distributions. Second, we introduce a contrastive loss that leverages relative difficulty information for unlabeled items by formulating an inequality between the normal distributions induced by the ICCs.

Experiments on real-world data from an e-learning platform show that our method improves binary cross-entropy by 2.02% over an MSE-based baseline when predicting student response correctness on unseen items.

1. INTRODUCTION

In recent years, the widespread adoption of online learning platforms has enabled the large-scale collection of learning logs and immediate feedback. Accordingly, personalized learning technologies that leverage data to assess learners' proficiency levels and progress, and to provide optimal questions from within the platform by considering item characteristics such as difficulty, have garnered significant attention [1, 21]. Consequently, identifying item characteristics within the platform is one of the critical challenges for the realization of personalized learning.

To measure item characteristics, item response theory (IRT) [12, 17, 26] is a widely adopted statistical framework that estimates item parameters, such as difficulty and discrimination, from students' response data and represents the probability of a correct response through an item characteristic curve (ICC) based solely on these item properties and student ability. The IRT framework has the advantage of enabling stable measurement of ability scores that are independent of test difficulty and student group characteristics, and it has been adopted in various fields, ranging from psychological experiments to large-scale tests such as the SAT and TOEFL.

In applying IRT frameworks, pretest measurement of item characteristics is typically conducted. To obtain stable item parameter estimates, it is necessary to secure a sufficiently large and ability-diverse sample of students and to ensure that they are adequately motivated to engage with the items. Consequently, for platforms containing a large volume of items, measuring the characteristics of every item through pretesting poses a significant challenge in terms of both temporal and financial resources.

To address these resource-intensive requirements, research on question difficulty estimation from text (QDET) [6], which leverages natural language processing (NLP) to estimate item characteristics directly from text, has become active.

In existing approaches of QDET, item parameters are typically predicted by formulating the task as a regression problem. For example, in the two-parameter logistic (2PL) model, a standard model in IRT, each item has two parameters, difficulty and discrimination, and these parameters are commonly predicted by minimizing the sum of squared errors for each parameter.

Since these two parameters collectively define the functional form of the ICC, it is more principled to formulate an ICC-based optimization task rather than individually minimizing the loss function for each parameter. Such an approach enables the inference of item characteristics aligned with learners' response accuracy, which is expected to capture the interplay between difficulty and discrimination, thereby improving overall predictive performance.

Furthermore, regression-based QDET is typically formulated as a supervised learning problem. Consequently, the training is restricted to items for which item characteristics, such as difficulty and discrimination, have been previously measured through IRT. However, in practical applications, even when explicit item difficulty or discrimination labels are absent, auxiliary data providing implicit signals are often available. For example, if problem sets are labeled as "beginner" or "advanced," it is natural to assume that items in the advanced set possess higher difficulty.

The contributions of this work are as follows.

- **Proposal of a new ICC-based supervised loss for QDET** : We propose a novel supervised loss term to jointly characterize the difficulty and discrimination parameters. This loss function is designed based on the discrepancy between latent variable distributions, focusing on the shape of the ICC.
- **Proposal of a new contrastive loss using unlabeled data for QDET** : We propose a novel contrastive loss term to incorporate unlabeled item texts. This loss term leverages auxiliary information to utilize items with unknown parameters, directly contributing to improved predictive performance.
- **Performance evaluation using real-world student response data**: We evaluate the effectiveness of our proposed loss terms by comparing them with conventional methods in terms of their ability to predict students' correct and incorrect responses on an actual e-learning platform.

Since our focus is on the loss function rather than a specific model architecture in this study, the experiments are conducted using relatively simple models. However, we expect them to be broadly applicable to QDET using 2PL models by replacing the training objective in existing text-to-parameter models.

2. RELATED WORK

In this work, we aim to estimate IRT item parameters, specifically difficulty and discrimination, directly from text by leveraging both supervised and contrastive learning. To ground our approach, we first review the foundations of IRT and the current state of QDET. Subsequently, we provide an overview of contrastive learning frameworks.

2.1 Item Response Theory

IRT is a modeling framework that predicts the probability of an examinee's correct response using parameters such as difficulty, discrimination, and student ability [12, 17, 26]. The item characteristic curve (ICC) describes the relationship between the probability of a correct response and the student's ability for given item parameters. Because of their interpretability and flexibility, IRT models are widely adopted in various fields, ranging from psychological experiments to large-scale standardized tests such as SAT and TOEFL.

In IRT, the one-parameter logistic (1PL) and two-parameter logistic (2PL) models are standard formulations [17, 26].

The 1PL model, also called the Rasch model, considers only item difficulty and student ability. The probability of a correct response by student j to item i is given by:

$$\sigma(D(\theta_j - b_i)), \tag{1}$$

where the sigmoid function $\sigma(x)$ is defined as $(1 + \mathrm{e}^{-x})^{-1}$. θ_j denotes the ability of the student j, and b_i denotes the difficulty of the item i. As b_i increases, the probability of a correct response to the item decreases; conversely, as θ_j increases, the student's probability of a correct response increases.

D is referred to as a scaling constant, typically set to 1.702 to ensure the following approximation holds [8]:

$$\int_{-\infty}^{x} \mathcal{N}(t|0,1)dt \simeq \sigma(Dx). \tag{2}$$

The 2PL model additionally accounts for the item discrimination parameter a_i. For student j, the probability of a correct response to item i is formulated as:

$$\sigma(Da_i(\theta_j - b_i)), \tag{3}$$

where a_i is a parameter that determines the slope of the curve. As item discrimination a_i increases, the probability of a correct response becomes more sensitive to the difference between θ_j and b_i, resulting in a steeper ICC. Consequently, a_i is an indicator for assessing how effectively an item differentiates between students of varying ability levels.

2.2 Question Difficulty Estimation from Text

To obtain stable item parameter estimates in IRT, it is necessary to secure a sufficiently large and ability-diverse sample of students while ensuring that they are adequately motivated to engage with the items. Consequently, the application of IRT in practice requires extensive field testing, which demands substantial temporal and financial resources. To address this challenge, QDET has been proposed as an approach that leverages NLP to infer item characteristics, such as difficulty, directly from text; for a comprehensive review, see [6].

In early QDET research, the prevailing approach involved applying feature engineering to item text and constructing regression models based on the resulting features. A representative example is R2DE [4, 5], which leverages TF-IDF [28] features to estimate IRT item parameters, specifically difficulty and discrimination.

In recent years, pre-trained language models (PLMs) such as BERT [10] and GPT [25] have emerged as one of the dominant approaches in NLP due to their ability to effectively

model complex linguistic contexts. Given their superior performance over conventional feature-based methods, PLM-based approaches have also been applied to QDET. For instance, Benedetto et al. demonstrated that using BERT and DistilBERT to predict IRT parameters outperforms traditional feature-driven models [3]. In addition, Lalor et al. proposed an approach that utilizes multiple PLMs as artificial crowds to generate responses for unlabeled items [13]. This framework enables the zero-shot estimation of IRT parameters based purely on model-generated responses, thus eliminating the need for labeled training data.

2.3 Contrastive Learning

Contrastive learning is a training framework that enhances model performance and representations by contrasting positive and negative samples. It has been widely adopted across various domains, including NLP, recommender systems, and computer vision [11, 24, 27].

In the field of educational technology, contrastive learning has been incorporated into several Knowledge Tracing (KT) studies, which aim to track students' proficiency over time. For instance, CL4KT generates negative samples by flipping answer correctness, enabling data augmentation grounded in contrastive learning [15]. Additionally, Q-MCKT demonstrates that the inclusion of contrastive learning during training improves prediction accuracy for items with sparse response data [29].

In recent years, one of the most commonly used loss functions in contrastive learning is InfoNCE [20, 22], which aims to maximize the difference between the scores of positive and negative samples. This loss function, also referred to as NT-Xent [9], is defined as follows:

$$-\mathbb{E}_{s_+}\left[\log \frac{\exp(s_+/\tau)}{\exp(s_+/\tau)+\sum_{s_-}\exp(s_-/\tau)}\right] \tag{4}$$

where τ is the temperature parameter, and $s_\pm$ are the scores of the positive and negative samples, respectively. When only a single negative sample is used, the loss function simplifies to:

$$-\mathbb{E}_{s_\pm}\left[\log\sigma\left(\frac{s_+ - s_-}{\tau}\right)\right], \tag{5}$$

which is referred to as the pairwise logistic loss or BPR loss [7, 27].

One of the advantages of contrastive learning is that a model can be trained without fully labeled data, provided that relative relationships between positive and negative samples are available. Consequently, it is extensively adopted in scenarios with limited labeled data. On many educational platforms, it is not uncommon for the volume of unlabeled items to far exceed those with labels, due in part to the high cost of obtaining labeled item parameters (e.g., difficulty and discrimination). Therefore, contrastive learning can be expected to be useful in such cases.

Despite this, the role of contrastive learning in IRT and QDET remains underexplored, as existing research has predominantly relied on supervised methods using labeled item parameters [2–5].

3. METHODOLOGY

We propose an ICC-based loss that combines supervised and contrastive terms for learning item parameters from text. The overall loss function $\mathcal{L}$ is defined as follows:

$$\mathcal{L} = \lambda\mathcal{L}_{\mathrm{CS}} + (1-\lambda)\mathcal{L}_{\mathrm{con}}, \tag{6}$$

where $\mathcal{L}_{\mathrm{CS}}$ and $\mathcal{L}_{\mathrm{con}}$ represent the supervised and contrastive loss terms, respectively. The hyperparameter λ balances the contributions of these two terms. The detailed definitions of $\mathcal{L}_{\mathrm{CS}}$ and $\mathcal{L}_{\mathrm{con}}$ are provided in the following subsections.

3.1 Supervised Loss

The item difficulty b_i and item discrimination a_i are inseparable parameters that jointly determine the ICC and the probability of a correct response. Therefore, instead of focusing on b_i and a_i as separate scalar values, we focus on the probability distribution of the latent variable z_i defined by these parameters. This approach enables us to directly optimize the joint distribution, yielding parameter estimates that better reflect the actual response behavior.

By defining the latent variable z_i as a random variable following a normal distribution, $z_i \sim \mathcal{N}(b_i, a_i^{-2})$ [16], the 2PL ICC in Eq. (3) can be approximated using the relationship established in Eq. (2):

$$\sigma(Da_i(\theta_j - b_i)) \simeq \Pr\{\theta_j > z_i \mid z_i \sim \mathcal{N}(b_i, a_i^{-2})\}. \tag{7}$$

Since z_i is a sample from a normal distribution with the difficulty parameter as its mean, it can be interpreted as the realized difficulty faced by examinees, accounting for noise due to factors such as testing conditions.

We define the supervised loss $\mathcal{L}_{\mathrm{CS}}$, which optimizes the predicted item parameters $\hat{b}_i$ and $\hat{a}_i$ so that the induced latent variable distribution $\mathcal{N}(z \mid \hat{b}_i, \hat{a}_i^{-2})$ is close to the target distribution $\mathcal{N}(z \mid b_i, a_i^{-2})$. Specifically, we employ the Cauchy-Schwarz divergence (CSD) [23], which serves as a measure of the discrepancy between two probability distributions. The supervised loss $\mathcal{L}_{\mathrm{CS}}$ is defined as follows:

$$\mathcal{L}_{\mathrm{CS}} = \mathbb{E}_{i\in\mathcal{D}_{\mathrm{CS}}}\left[L_i^{\mathrm{CS}}\right], \tag{8}$$

$$\begin{aligned} L_i^{\mathrm{CS}} &= -\log \frac{\int \mathcal{N}(z \mid \tilde{b}_i, \tilde{a}_i^{-2})\mathcal{N}(z \mid b_i, a_i^{-2})\mathrm{d}z}{\sqrt{\int \mathcal{N}(z \mid b_i, a_i^{-2})^2\mathrm{d}z \int \mathcal{N}(z \mid \tilde{b}_i, \tilde{a}_i^{-2})^2\mathrm{d}z}} \\ &= \frac{(b_i - \tilde{b}_i)^2}{2(a_i^{-2} + \tilde{a}_i^{-2})} + \frac{1}{2}\log\frac{a_i^{-2} + \tilde{a}_i^{-2}}{2a_i^{-1}\tilde{a}_i^{-1}}, \end{aligned} \tag{9}$$

where L_i represents the discrepancy for a single item i. Here, $\mathcal{D}_{\mathrm{CS}}$ is the set of items whose difficulty and discrimination are known.

We also experimented with other closed-form distributional discrepancies (e.g., Kullback–Leibler divergence and Hellinger distance). Among them, CSD yielded the best performance in our experiments(Appendix B).

3.2 Contrastive Loss

We denote (i_+, i_-) as an ordered pair of items where the relative difficulty order is determined by auxiliary information, such as metadata tags or learning course titles. The

contrastive loss $\mathcal{L}_{\text{con}}$ is defined based on the negative log-likelihood of the relationship $z_+ > z_-$, formulated as follows:

$$\mathcal{L}_{\text{con}} = \mathbb{E}_{i_\pm \in \mathcal{D}_{\text{con}}} \left[L_{i_\pm}^{\text{con}} \right] \tag{10}$$

$$L_{i_\pm}^{\text{con}} = -\log \Pr\{z_+ > z_- \mid z_\pm \sim \mathcal{N}(\tilde{b}_{i_\pm}, \tilde{a}_{i_\pm}^{-2})\} \tag{11}$$

$$= -\log \int_0^\infty \mathcal{N}(x \mid \tilde{b}_{i_+} - \tilde{b}_{i_-}, \tilde{a}_{i_+}^{-2} + \tilde{a}_{i_-}^{-2}) \mathrm{d}x \tag{12}$$

$$\simeq -\log \sigma \left(D \frac{\tilde{b}_{i_+} - \tilde{b}_{i_-}}{\sqrt{\tilde{a}_{i_+}^{-2} + \tilde{a}_{i_-}^{-2}}} \right). \tag{13}$$

Here, $\mathcal{D}_{\text{con}}$ is the set of item pairs for which only the relative order of difficulty is known. In Eq. (13), we used the approximation given by Eq. (2).

4. EXPERIMENTS

We conduct experiments to clarify the following two points.

- The supervised loss $\mathcal{L}_{\text{CS}}$ yields more accurate predictions of correct responses compared to mean squared error (MSE).
- Adding the contrastive loss $\mathcal{L}_{\text{con}}$ improves model performance.

4.1 Dataset

Table 1: Dataset sizes used in this study

(a) training and validation

	Supervised	Contrastive	
		pair	unique
English	763	90,531	3,069
Mathematics	745	43,756	4,979
Japanese	398	100,687	1,242
Social Studies	118	85,567	10,169
Total	2,024	263,271	19,459

(b) Evaluation response logs

	log	unique item	unique student
English	33,595	75	457
Mathematics	39,017	156	415
Japanese	39,418	114	451
Social Studies	25,118	179	319
Total	137,148	524	1,642

As experimental data, among the materials available on ZEN Study[1], an e-learning platform for students, we selected learning materials designed for junior high and high school students. We focused on the four subjects for which a dedicated pretest was conducted: English, Mathematics, Japanese, and Social Studies. Since the platform manages its materials in HTML format, we performed preprocessing by removing non-text elements (e.g., images and hyperlinks), eliminating duplicate and highly similar materials, and converting the content to Markdown.

[1] `https://www.nnn.ed.nico`

The sizes of the datasets used in our experiments are shown in Table 1. To evaluate the model's performance on unseen items, the supervised training and evaluation datasets are disjoint.

From this supervised dataset, we held out 10% of the items from training directly and used them only for hyperparameter tuning and early stopping. The item characteristics used as supervised training data were estimated under a Bayesian 2PL IRT framework, with normal priors placed on item difficulty and learner ability and a log-normal prior on item discrimination to enforce positivity.

For the contrastive training data, we leveraged auxiliary information available on the e-learning platform (e.g., metadata tags and course titles). Specifically, we selected candidate pairs of items from similar topics, such as those belonging to the same chapter or whose titles became identical after stripping prefix/suffix tags and numbers. From these candidates, we used only pairs whose metadata, such as course names, tags, or title prefixes/suffixes, clearly indicated a difference in difficulty between the two items , excluding those with comparable difficulty levels. Pairs with comparable difficulty levels in the metadata were excluded. To address the data imbalance across subjects, the sampling probabilities during training were adjusted to ensure that each subject (e.g., English, Mathematics, Japanese, and Social Studies) was sampled with equal probability. The sizes of these supervised and contrastive datasets are summarized in Table 1a.

In addition, we conducted an independent evaluation test administration to assess the model's performance; the sizes of this evaluation dataset are summarized in Table 1b. The "log" column indicates the number of student-item response records, while the "item" and "student" columns show the counts of unique items and unique students, respectively. If the same student participated in multiple subjects, they were treated as distinct students for each subject.

4.2 Model Architecture

As in conventional QDET, the model is based on neural networks and is designed to jointly predict item difficulty and discrimination from question text. As illustrated in Figure 1, the architecture consists of two primary components: a text encoder and a feed-forward network (FFN). To highlight the impact of the loss terms, we adopt a simple model architecture so that performance differences can be attributed primarily to the training objective.

4.2.1 Text-Encoder

For each item, the Markdown text is input to the encoder to compute a d_{enc}-dimensional text embedding. We utilized a pre-trained language model (PLM) as the text encoder and kept its parameters frozen while training the remaining components. Specifically, we employed Gemini Embedding [14] with its default output dimension of $d_{\text{enc}} = 3{,}072$.

4.2.2 Feed-Forward Network

Given the text embedding $\boldsymbol{e}_i$, we employ an FFN to estimate the item difficulty $\tilde{b}_i$ and discrimination $\tilde{a}_i$:

$$\boldsymbol{h}_i = \mathrm{ReLU}(W\boldsymbol{e}_i + \boldsymbol{w}_0) \tag{14}$$

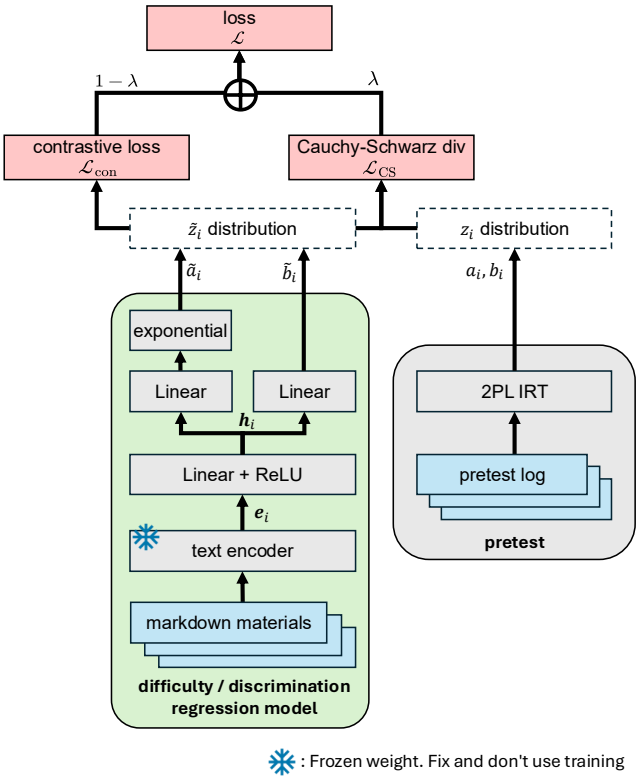

Figure 1: Overview of the experiments. The text encoder is kept frozen, and only the feed-forward network (FFN) is trained. We estimate the distribution of z_i using the regression model and a pre-test, and use it to define the loss function.

$$\tilde{b}_i = \boldsymbol{w}_b^T \boldsymbol{h}_i + w_{b0} \qquad \tilde{a}_i = \exp(\boldsymbol{w}_a^T \boldsymbol{h}_i + w_{a0}) \tag{15}$$

where $W \in \mathbb{R}^{d_h \times d_{\text{enc}}}$, $\boldsymbol{w}_0 \in \mathbb{R}^{d_h}$, $\boldsymbol{w}_b, \boldsymbol{w}_a \in \mathbb{R}^{d_h}$, and $w_{b0}, w_{a0} \in \mathbb{R}$ are learnable parameters. We set the hidden dimension to $d_h = 64$. ReLU denotes the rectified linear unit activation function, defined as $\text{ReLU}(x) = \max\{x, 0\}$ [19]. As the discrimination parameter must be positive, an exponential transformation is applied to the corresponding FFN output.

4.3 Evaluation

To benchmark the effectiveness of our proposed CSD-based supervised loss $\mathcal{L}_{\text{CS}}$, we compare against a baseline model that employs MSE of the difficulty and discrimination parameters as the loss function. Furthermore, as an ablation study to verify the effectiveness of the contrastive loss $\mathcal{L}_{\text{con}}$, we also compare it with a model that removes the contrast loss term. We also introduce a baseline that applies the pairwise logistic loss (Eq. 5) only to the difficulty parameter; in this setting, the temperature τ is fixed at D^{-1}.

As the primary evaluation metric, we calculate the binary cross-entropy (BCE) over the evaluation response logs, between the observed student correctness and the predicted response probability. The predicted probability for student j on item i is computed via Eq. (3) using the predicted item parameters $(\tilde{a}_i, \tilde{b}_i)$ and the student ability θ_j estimated from pretests:

$$\mathbb{E}_{i,j}[y_{ij} \log \sigma(D\tilde{a}_i(\theta_j - \tilde{b}_i)) + (1 - y_{ij}) \log(1 - \sigma(D\tilde{a}_i(\theta_j - \tilde{b}_i)))]. \tag{16}$$

Here, $y_{ij} \in \{0, 1\}$ denotes the observed correctness of student j on item i. To provide further insight into parameter estimation accuracy, we also evaluate the performance using the Root Mean Squared Error (RMSE) for difficulty and discrimination, as well as the CSD for each item.

4.4 Implementation Details

The learning rate was set to 1×10^{-4}, and we used the AdamW optimizer [18]. The batch size was set equal to the total size of the supervised training dataset. Training used early stopping, and patience set to 200 epochs. The hyperparameter λ was tuned via grid search over the range $\{0.1, 0.2, \ldots, 0.9\}$.

5. RESULT

To validate the effectiveness of $\mathcal{L}_{\text{CS}}$ and $\mathcal{L}_{\text{con}}$, we compute the BCE for student response correctness on the evaluation dataset, and measure the CSD and RMSE for each item. These results are summarized in Table 2. The hyperparameters λ reported are those that achieved the lowest Average BCE during our grid search. The "pretest" column shows the BCE computed using item parameters directly estimated from student response logs, which serves as a theoretical performance ceiling for the models.

First, we examine the performance of our proposed CSD loss compared to the conventional MSE loss. The CSD loss achieved better performance than the MSE loss in almost all metrics, and this trend was observed regardless of whether contrastive learning was used. Compared to the baseline MSE value (0.5987 ± 0.0008), switching the supervised loss to CSD yielded (0.5882 ± 0.0003), corresponding to a 1.75% relative improvement in BCE; here, values are reported as the mean $\pm$ standard deviation over five independent runs. A paired t-test was conducted to compare the average BCE, yielding a p-value of 8×10^{-7} and the null hypothesis was rejected. Improvements were observed across all four subjects—English, Mathematics, Japanese, and Social Studies. In terms of BCE, the CSD-based model outperformed the MSE-based model in every subject.

Next, we evaluate the impact of contrastive learning. Regardless of the supervised loss employed (CSD or MSE), incorporating our proposed contrastive loss (Eq. (13)) improved performance on all metrics except RMSE-a. Furthermore, the proposed contrastive loss outperformed the pairwise-logistic loss (Eq. (5)), in many metrics including BCE. In particular, under the baseline MSE supervised loss, introducing our contrastive objective improved BCE from 0.5987 ± 0.0008 to 0.5972 ± 0.0008, corresponding to a 0.25% relative improvement. A paired t-test was conducted to compare the average BCE, yielding a p-value of 2×10^{-3} and the null hypothesis was rejected.

However, we did not observe a clear improvement in RMSE-a. With the CSD supervised loss, we speculate that this is because our objectives emphasize aspects directly related to student correctness, rather than regions where the discrimi-

Table 2: Evaluation metrics (BCE, CSD, RMSE-b, and RMSE-a) on the test set for each loss term. The best metrics for each loss term are highlighted in bold. The "pretest" column serves as a reference, representing the BCE computed using the item parameters directly estimated from the pretest response logs (ground truth). For the contrastive loss columns, "a, b" and "b" designate the variations defined by Eq. (13) and Eq. (5), respectively, while "nothing" denotes the absence of the contrastive term.

nation parameter a becomes excessively large or small. For contrastive learning, we expected our proposed loss (Eq. (13)), which explicitly incorporates both a and b, to yield a smaller RMSE$-a$ than the pairwise-logistic loss (Eq. (5)) that learns only b; however, this was not observed in our experiments. This point requires more in-depth investigation in future work. This point requires more in-depth investigation in future work, particularly regarding which types of contrastive item pairs contribute to better generalization.

Overall, our proposed two loss terms resulted in the highest predictive accuracy across the evaluated metrics, underscoring the effectiveness of the proposed framework for the QDET task. Compared to the conventional MSE baseline without contrastive learning (BCE: 0.5987±0.0008), our proposed loss combination (CSD with the proposed contrastive loss) achieved a BCE of 0.5866±0.0007, corresponding to a 2.02% relative improvement.

6. LIMITATIONS AND FUTURE WORK

Our study focuses on a 2PLM-based neural regression model for estimating item difficulty and discrimination directly from question texts. Consequently, it remains to be explored whether our proposed method is applicable to other IRT formulations, such as the 1PL or 3PL models, and whether such extensions would yield similar benefits. In addition to neural regression models, QDET encompasses diverse approaches, including those leveraging artificial crowds [13]. Integrating our method with such approaches remains a challenge for future work.

Furthermore, it remains to be verified whether this approach can contribute to the realization of personalized learning and the enhancement of the student learning experience. Consequently, the practical utility of the proposed method for educational applications should be substantiated through further experimental studies on real-world e-learning platforms.

7. CONCLUSION

This study proposes two loss terms for estimating question difficulty and discrimination from text, with a focus on the ICC and contrastive learning. First, we introduced a supervised loss term designed to align the model's latent variable distribution with that of the training data. Second, leveraging relative difficulty orders derived from auxiliary information, we proposed a contrastive loss term based on the order

of latent variables.

Using real-world data from an e-learning platform, the experiments confirmed that the proposed loss terms outperform baseline methods in predicting student response correctness, achieving a 2.02% improvement in BCE. These results demonstrate the potential of the method to reduce the costs associated with large-scale pretesting and to contribute to the reliable estimation of item parameters.

APPENDIX

A. DERIVATION EQUATIONS

A.1 Derivation cumulative distribution function from the 2PL ICC

Equation (7) can be rewritten as

$$\Pr\{\theta_j > z_i \mid z_i \sim \mathcal{N}(b_i, a_i^{-2})\} \tag{17}$$

$$= \Pr\left\{ \frac{z_i - b_i}{a_i^{-1}} < a_i(\theta_j - b_i) \,\middle|\, z_i \sim \mathcal{N}(b_i, a_i^{-2}) \right\} \tag{18}$$

$$= \Pr\{t < a_i(\theta_j - b_i) \,|\, t \sim \mathcal{N}(0,1)\} \tag{19}$$

$$= \int_{t < a_i(\theta_j - b_i)} \mathcal{N}(t \mid 0,1)\, dt \tag{20}$$

$$\simeq \sigma\big(D a_i(\theta_j - b_i)\big). \tag{21}$$

A.2 Derivation of the supervised loss

We define the per-item supervised loss by the Cauchy–Schwarz divergence:

$$L_i[p_i(z), q_i(z)] = -\log \frac{\int p_i(z) q_i(z)\, dz}{\sqrt{\left(\int p_i(z)^2\, dz\right)\left(\int q_i(z)^2\, dz\right)}}. \tag{22}$$

$$p_i(z) = \mathcal{N}(z \mid b_i, a_i^{-2}), \qquad q_i(z) = \mathcal{N}(z \mid \tilde{b}_i, \tilde{a}_i^{-2}). \tag{23}$$

The following identity holds for the integral of the product of two Gaussian densities.

$$\int \mathcal{N}(x|\mu_1, \sigma_1^2)\mathcal{N}(x|\mu_2, \sigma_2^2) dx \quad = \frac{\exp\left(-\frac{(\mu_1 - \mu_2)^2}{2(\sigma_1^2 + \sigma_2^2)}\right)}{\sqrt{2\pi(\sigma_1^2 + \sigma_2^2)}} \tag{24}$$

Therefore, the integrals in Eq.(22) can be evaluated as follows:

$$\int p_i(z) q_i(z) dz = \frac{\exp\left(-\frac{(b_i - \tilde{b}_i)^2}{2(a_i^{-2} + \tilde{a}_i^{-2})}\right)}{\sqrt{2\pi(a_i^{-2} + \tilde{a}_i^{-2})}} \tag{25}$$

$$\int p_i(z)^2 dz = \frac{a_i}{2\sqrt{\pi}} \qquad \int q_i(z)^2 dz = \frac{\tilde{a}_i}{2\sqrt{\pi}} \tag{26}$$

Substituting these expressions into Eq. (22), we obtain the closed-form expression

$$L_i[p_i(z), q_i(z)] = \frac{(b_i - \tilde{b}_i)^2}{2(a_i^{-2} + \tilde{a}_i^{-2})} + \frac{1}{2} \log \frac{a_i^{-2} + \tilde{a}_i^{-2}}{2 a_i^{-1} \tilde{a}_i^{-1}} \tag{27}$$

.

A.3 Derivation of the contrastive loss

$$\Pr\{z_+ > z_- \mid z_\pm \sim \mathcal{N}(b_\pm, a_\pm^{-2})\} \tag{28}$$

$$= \Pr\{x > 0 \mid x \sim \mathcal{N}(b_+ - b_-, a_+^{-2} + a_-^{-2})\} \tag{29}$$

$$= \int_0^\infty \mathcal{N}(x | b_+ - b_-, a_+^{-2} + a_-^{-2}) dx \tag{30}$$

$$= \int_{-\frac{b_+ - b_-}{a_+^{-2} + a_-^{-2}}}^{\infty} \mathcal{N}(t|0,1) dt \tag{31}$$

$$= \int_{-\infty}^{\frac{b_+ - b_-}{a_+^{-2} + a_-^{-2}}} \mathcal{N}(t|0,1) dt \tag{32}$$

$$\simeq \sigma\left(D \frac{b_+ - b_-}{a_+^{-2} + a_-^{-2}}\right) \tag{33}$$

B. ALTERNATIVE SUPERVISED LOSSES

Before fixing CSD as our supervised objective, we conducted a preliminary experiment to determine which metric is most suitable for measuring the similarity between the latent-variable distributions. As candidate metrics, we selected divergences that admit closed-form expressions between two Gaussian distributions, so that they can be incorporated into training without numerical approximation. Specifically, we compared CSD with the Kullback–Leibler (KL) divergence and the Hellinger distance, while keeping the rest of the training framework unchanged. Table 3 summarizes the resulting BCE on the evaluation set for each supervised loss, combined with the three contrastive settings considered in the main paper. The results show that CSD consistently achieved the lowest BCE across all three contrastive settings.

Table 3: Additional comparison of supervised losses on the evaluation BCE. The contrastive settings "a, b", "b", and "nothing" follow the definitions used in Table 2.

	supervised loss			
contrastive loss	CSD	KL	Hellinger	MSE
a, b	**0.5866**	0.5934	0.5892	0.5972
b	**0.5876**	0.5950	0.5914	0.5978
nothing	**0.5882**	0.5957	0.5894	0.5987

The KL divergence and Hellinger distance used in this comparison are given below:

$$\mathrm{KL} = \log \frac{\tilde{a}}{a} + \frac{a^2}{2}\left\{\tilde{a}^{-2} + (\tilde{b} - b)^2\right\} - \frac{1}{2} \tag{34}$$

$$\text{Hellinger} = 1 - \sqrt{\frac{2a\tilde{a}}{a^2 + \tilde{a}^2}} \exp\left\{-\frac{(b - \tilde{b})^2 a^2 \tilde{a}^2}{4(a^2 + \tilde{a}^2)}\right\} \tag{35}$$

ABSTRACT

Knowledge Tracing (KT) models often underperform for students with short interaction histories, creating a temporal equity gap between early- and late-stage learners. We tackle this issue by fusing behavioral traces with dialogue-derived signals using a lightweight reinforcement-learning (RL) gate that adaptively reweights evidence across the learning trajectory. To make temporal disparities explicit, we evaluate by student-level practice-volume cohorts (deciles from 10% to 100%) and report ACC/AUC within cohorts and overall. Across both backbones, the RL-gated variant consistently improves aggregate accuracy and AUC while reducing across-cohort variance, yielding flatter, more reliable cohort curves relative to a behavioral-only baseline and a naïve feature-augmented model without gating. These findings suggest a practical design principle for next-generation knowledge tracing systems: when interaction histories are sparse, semantically rich auxiliary signals can stabilize prediction, and as histories accumulate, the model can shift back toward behavioral evidence. We discuss limitations particularly the reliance on rich interaction data, and outline directions for testing on public datasets with sufficient depth or proxy signals, as well as for exploring stronger equity objectives and interpretable gating.

Keywords

Knowledge Tracing; Temporal Equity; Reinforcement Learning; Conversational Features; LLM; DKT; SAKT.

1. INTRODUCTION

Knowledge Tracing (KT) has become a cornerstone of modern educational technology [10], especially in the development of intelligent tutoring systems [34]. KT models predict students' knowledge states based on their learning interactions [10]. Computer-supported education systems rely on KT to personalize learning experiences and optimize instructional decisions [17, 21]. However, recent research reveals a concerning pattern: existing KT models, including classical Bayesian Knowledge Tracing (BKT) and Deep Knowledge Tracing (DKT), often fail to achieve equitable tutoring across different student populations, exhibiting systematic bias against certain groups [13, 29]. While early-stage prediction methods have shown effectiveness in some domains via statistical approaches such as survival analysis [14], KT presents temporal fairness challenges that extend beyond traditional demographic disparities. A critical, under-explored dimension of fairness involves the differential treatment of early-stage learners with limited interaction histories versus experienced learners with extensive practice records. This temporal bias manifests as less accurate predictions for early-stage students due to sparse sequential data, leading to suboptimal recommendations during crucial initial phases; this phenomenon corresponds to the well-known *cold-start* problem in both knowledge tracing and recommender systems [7, 9]. Conversely, experienced learners benefit from rich histories that enable more precise knowledge estimation, creating a "rich-get-richer" effect in which students who need the most support receive the least accurate guidance.

To address temporal fairness in KT, we present a three–tier comparative framework evaluated on two standard backbones (DKT and SAKT). The Baseline relies on behavioral traces only (skill, correctness, optionally difficulty/response time). The +Features model augments the baseline with time–aligned conversation–derived signals (dialogue–rubric vectors and unit–level mastery indicators) designed to avoid temporal leakage. The +Features+RL model adds a gating mechanism trained with policy–gradient updates to adaptively weight behavioral versus conversational streams across a learner's trajectory. We operationalize temporal equity via *percent–progress bins* (10%, 20%, ..., 100%), explicitly targeting more reliable predictions for early–stage learners while preserving overall performance [5, 10, 20, 21, 26]. This framing is especially relevant as tutoring systems become more conversational. In newer AI-mediated environments, dialogue is part of the instructional process itself, which makes dialogue-integrated KT increasingly practical even if it remains inapplicable to many legacy benchmark datasets [2, 11, 15].

Our contributions are threefold. (1) We formulate a fairness–aware optimization for KT that treats disparity across progress bins as an explicit signal, enabling adaptive fusion of heterogeneous evidence through an RL gate. (2) We integrate conversation–derived features with behavioral traces using leak–conscious, step–aligned fusion, offering a

practical path to richer KT without compromising temporal validity. (3) We provide a systematic comparison across backbones and variants and visualize progress–aligned performance with cohort–size overlays, demonstrating qualitatively flatter, more equitable curves for the RL–gated model while maintaining competitive aggregate accuracy and AUC. Detailed metrics and variant comparisons are reported in the Results section.

2. RELATED WORK

2.1 Knowledge Tracing

Classical KT models, most notably BKT, represent mastery as a latent state updated from response histories with parameters for initialization, learning, slip, and guess [10]. Subsequent extensions account for learner heterogeneity and temporal dynamics, including individualized BKT [31] and time-aware variants that model spacing and forgetting [22, 23]. Neural KT reframes KT as sequence modeling: DKT uses recurrent encoders to predict next-step correctness from interaction sequences [21], while attention-based architectures such as SAKT capture relevance among past items and skills through query–key attention [20, 33].

Two practical challenges motivate our work. First, modern KT often relies primarily on correctness patterns and student–item interactions, which can underutilize rich side information such as problem text, hints, or conversational evidence [1]. Second, directly injecting auxiliary signals risks temporal leakage if features are not carefully aligned to the prediction horizon (e.g., using future turns of a dialogue to predict the present step) [12, 24]. Our setting exposes both issues: we have post-problem dialogues that are potentially informative, but any benefit hinges on leak-conscious alignment and on a mechanism that can adapt how much the model should rely on these signals at different stages of a learner's trajectory. Moreover, KT systems face a form of the cold-start problem analogous to recommender systems—predictions are less reliable for students with sparse histories [7, 9]. We therefore complement standard overall metrics with a progress-aware analysis to make such temporal effects explicit.

2.2 Fairness in Educational AI and KT

A growing literature examines disparate outcomes in educational AI [8, 32]. In KT specifically, studies have surfaced systematic gaps across student subgroups and contexts, raising fairness concerns for data-driven personalization [13, 29]. Some work explores modeling choices aimed at mitigating disparities (e.g., time-augmented BKT) [6], while others document construct-related effects such as reading-ability gaps in math KT or platform/socioeconomic biases in second-language KT [25, 27].

Our perspective focuses on temporal equity: comparable predictive performance for learners at early vs. late stages. In conventional training, aggregate objectives naturally overweight data-rich trajectories; learners with short histories precisely those who need the most reliable guidance—can receive noisier predictions. We operationalize this dimension by grouping students into deciles based on total practice volume (10%–100%) and reporting performance by cohort. This differs from demographic fairness (which we do not analyze here) but is practically salient for tutorial decision making: reliable early-stage estimation can prevent compounding errors, while later stages may benefit more from accumulated behavioral evidence. Our equity lens thus aims at flattening cohort-wise performance curves, not enforcing strict parity at the expense of accuracy, and it aligns with the cold-start framing noted above [7, 9].

2.3 Reinforcement Learning in Educational AI

Reinforcement learning (RL) has been widely studied for sequencing and recommendation problems in education, treating personalization as a sequential decision process [3, 19]. Applications include curriculum sequencing and learning-path optimization as well as broader decision-making frameworks [4, 18, 28]. Much of this work, however, optimizes a single objective (e.g., learning gain, engagement) and gives limited attention to fairness-aware architectural adaptation.

In contrast, we use RL not to select content but to adapt model fusion. Concretely, a lightweight gate produces a convex weight that fuses behavioral and conversation/unit streams, with a policy-gradient objective [26] that balances predictive utility and a temporal-equity penalty defined over practice-volume cohorts. This framing has three practical advantages. First, it is model-agnostic: the gate can sit atop standard KT backbones (e.g., DKT, SAKT) without architectural overhaul. Second, it directly targets equity at the level of the evaluation protocol (deciles by practice volume), avoiding a mismatch between training goals and assessment. Third, it supports history-adaptive reliance on auxiliary signals: conversational features can carry more weight where behavioral evidence is scarce and recede when long histories suffice. Our empirical results (Section Results) suggest that such equity-aware fusion can reduce across-cohort variance while maintaining overall accuracy, providing a cautious but actionable path toward temporally robust KT.

3. METHOD

3.1 Data Description

We analyze logs from a deployed middle–school mathematics platform in which each problem–solving attempt may be followed by an optional chatbot conversation. The corpus spans approximately one academic term (about eight months) and contains 2,678 students, 1,605 items (three difficulty bands), and 10,877 problem–solving instances linked to up to 31 skills/competencies, with an overall correctness of about 47%. Each step records an item/skill identifier, binary correctness, and elapsed time; when present, the post–problem dialogue consists of multiple turns between the student and the chatbot (on average, about 1.47 post–problem conversations per attempt and about 7.97 turns). These characteristics provide the empirical context and are consistent with prior descriptions of the same platform.

The data analyzed in this study were derived from the ALTER-Math project [30]. The underlying human-subjects study was reviewed and approved by the Institutional Review Board (IRB) at the University of Florida (IRB202301838). All research procedures involving human participants in the source study were conducted in accordance with the ethical standards of the University, and informed consent was obtained from all participants prior to their inclusion in the study.

For the present analysis, only de-identified learner log data and post-problem dialogue data were used.

To assess how performance varies with the amount of prior history, we group *students* by their total number of attempted problems and form ten learner cohorts at the deciles: 10%, 20%, ..., 100%. Unless otherwise noted, we report Accuracy (ACC) and AUC *within each cohort* and overall. This cohorting emphasizes reliability for learners with *sparse* vs. *rich* practice histories and is used consistently across all experiments.

3.2 LLM–Derived Dialogue Features

Beyond behavioral traces, we incorporate features distilled from the post–problem conversation. Feature extraction is conducted *offline* using an instruction–tuned LLaMA–family model, Llama-3-8B-Instruct, with decoding parameters temperature = 0, top-p = 0.9, and max_tokens = 128, running on a single A100–80GB GPU [16]. The resulting numeric features are then *time–aligned* to the KT sequence so that features used at step t reflect only information available up to (and including) t, preventing temporal leakage. We use two groups of dialogue features:

1. Rubric vector (fixed–length): aggregated indicators that summarize the conversation signals most relevant to KT—e.g., knowledge–point mentions/coverage, clarification/help–seeking, confusion/uncertainty cues, correctness–related evidence, and engagement tone—computed per solved item from the dialogue that follows that item.
2. Unit–level mastery (scalar per step): an LLM–based verdict on whether the learner evidences mastery of the curricular unit associated with the current item.

Both groups are exported as numeric features and concatenated as an auxiliary stream; missing dialogues at a step are zero–imputed for the rubric vector with a neutral default for mastery.

3.3 Models

We instantiate two standard knowledge–tracing backbones and build three variants on each:

DKT encodes the interaction sequence with a recurrent network and outputs a behavioral logit $z_t^{(\mathrm{beh})}$ for step t [21]. SAKT aggregates relevant past items via self–attention to produce $z_t^{(\mathrm{beh})}$ [20].

1. **Baseline (behavioral only)** uses the behavioral stream (skill×correctness) with available covariates (difficulty, response time).
2. **+Features** concatenates the *rubric vector* and the unit-mastery scalar as an auxiliary stream $X_t^{(\mathrm{conv})}$ that is strictly step–aligned (forward–only).
3. **+Features+RL** adds a lightweight *gating* mechanism that produces a convex weight $\alpha_t \in [0,1]$ each step and fuses streams:

$$z_t \;=\; \alpha_t\, z_t^{(\mathrm{beh})} \;+\; \big(1-\alpha_t\big)\, z_t^{(\mathrm{conv})}, \qquad \hat{p}_t \;=\; \sigma(z_t).$$

3.4 Fairness–Aware Reinforcement–Learning Gate

The gate is trained with policy–gradient updates [26] to preserve overall predictive utility while discouraging steep disparities across learner cohorts (10–100% by practice volume). Concretely, we maximize the objective

$$\mathcal{J} = \underbrace{\mathbb{E}\big[\mathrm{Perf}(\hat{p}_t, r_t)\big]}_{\text{overall utility}} - \lambda_{\mathrm{fair}} \cdot \underbrace{\Phi\big(\{\mathrm{Perf}_c\}_{c=1}^{10}\big)}_{\text{temporal–equity penalty}} + \lambda_{\mathrm{ent}} \cdot \underbrace{\mathbb{H}[\alpha_t]}_{\text{entropy}}.$$

where Perf denotes a differentiable surrogate aligned with ACC/AUC, Φ penalizes large performance gaps/variance across the ten practice–volume cohorts, and $\mathbb{H}$ regularizes the gate to avoid premature collapse. Intuitively, the gate can rely more on conversational evidence for learners with short histories and gradually shift toward behavioral evidence as history accumulates, aiming for flatter, more equitable cohort curves without sacrificing aggregate accuracy.

3.5 Training and Evaluation

All variants minimize masked cross–entropy over valid steps. Unless otherwise noted, we keep the same data splits, batch size, and training epochs across backbones/variants to enable controlled comparison.[1] We report Accuracy (ACC) and AUC *within each learner cohort* (10–100% by practice volume) and overall. Plots overlay a dashed right axis indicating the number of students per cohort to contextualize variance across groups with fewer vs. more interactions. Results are reported for DKT and SAKT under identical cohort definitions and evaluation code.

4. RESULTS

4.1 Setup for Temporal-Equity Evaluation

All models are evaluated by percent progress (10%, 20%, ..., 100%) computed per learner from the normalized position t/T. For each bin and overall we report Accuracy (ACC) and AUC. Plots include a dashed right axis showing cohort size per bin (students when available; otherwise interactions), enabling visual inspection of stability vs. noise across the trajectory.

4.2 Aggregate Trends Across Backbones

Figures 1 a-d show per-bin AUC/ACC for DKT and SAKT. In both backbones, +Features+RL yields the strongest curves overall and particularly in early-to-mid progress bins where histories are short. The dashed right axes indicate that bins with fewer data points (or fewer students) have more volatile performance; even there, +Features+RL maintains a consistent advantage.

Table 1 summarizes percent-bin statistics (mean, SD, min, max, median) by model/variant. On DKT, +Features+RL improves mean AUC from 0.5985 (baseline) to 0.6094 and mean ACC from 0.5738 to 0.5877. On SAKT, +Features+RL

[1]In our runs we used a batch size of 64 and trained for 12 epochs per setting.

Table 1: Percent-progress bin statistics (mean ± SD, with min/max and median) by backbone and variant.

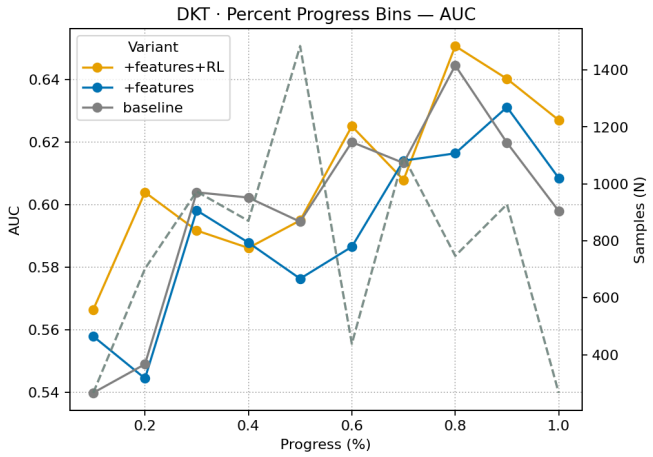
Backbone	Variant	ACC_{mean}	ACC_{SD}	ACC_{min}	ACC_{max}	ACC_{med}
DKT	baseline	0.5738	0.0253	0.5184	0.6064	0.5777
DKT	+features	0.5777	0.0242	0.5285	0.6165	0.5749
DKT	+features+RL	*0.5877*	*0.0205*	*0.5609*	*0.6212*	*0.5877*
SAKT	baseline	0.5596	0.0321	0.4887	0.6013	0.5715
SAKT	+features	0.5677	0.0291	0.5000	0.6005	0.5744
SAKT	+features+RL	*0.5872*	*0.0231*	*0.5527*	*0.6171*	*0.5880*

Backbone	Variant	AUC_{mean}	AUC_{SD}	AUC_{min}	AUC_{max}	AUC_{med}
DKT	baseline	0.5985	0.0320	0.5398	0.6445	0.6031
DKT	+features	0.5921	0.0272	0.5444	0.6312	0.5930
DKT	+features+RL	*0.6094*	*0.0261*	*0.5664*	*0.6507*	*0.6059*
SAKT	baseline	0.5792	0.0396	0.4829	0.6155	0.5969
SAKT	+features	0.5754	0.0315	0.5159	0.6113	0.5900
SAKT	+features+RL	*0.6027*	*0.0225*	*0.5666*	*0.6349*	*0.6066*

Notes. (i) Statistics are computed over ten student-level practice-volume cohorts (deciles: 10%, 20%, . . . , 100%). For each cohort we evaluate ACC and AUC, then summarize across cohorts (mean, SD, min, max, median). (ii) *Underlined italics* mark the best value within each row group (per backbone across variants): for *means/medians/max*, higher is better; for *SD*, lower is better (flatter, more equitable across cohorts); for *min*, higher indicates stronger worst-cohort performance. (iii) The `+features+RL` variant consistently achieves the highest means and lowest SDs across both backbones, suggesting the RL gate boosts overall quality while reducing dispersion across practice-volume cohorts. (iv) Min/max arise from different cohorts (early vs. late); interpret alongside SD and cohort sizes (shown in the figures' dashed right axes) to understand variability under sparse vs. rich histories.

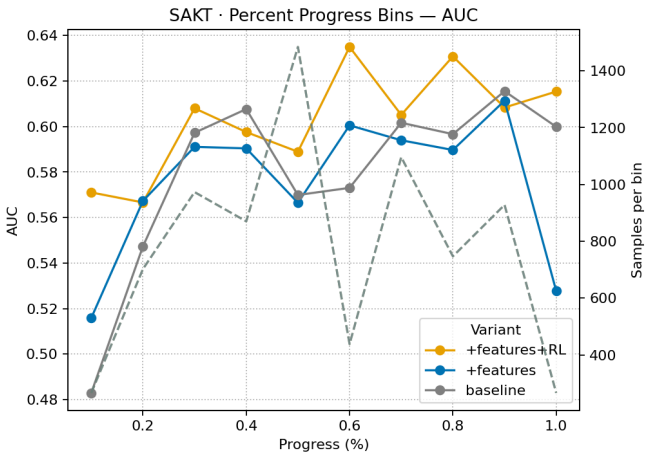
raises mean AUC from 0.5792 (baseline) to 0.6027 and mean ACC from 0.5596 to 0.5872. Notably, +Features (without RL) shows mixed effects on AUC (slightly below baseline on both backbones), indicating that naive fusion of conversational/unit features can be suboptimal; the RL gate appears necessary to realize consistent gains.

4.3 Variance Reduction and Curve Flattening



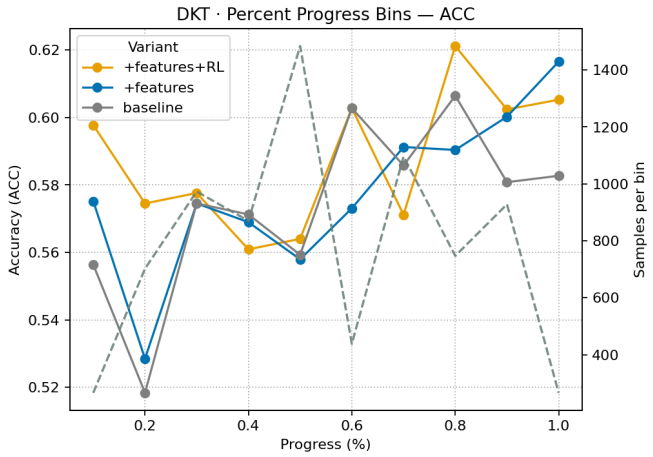
Beyond mean improvements, +Features+RL consistently reduces across-bin variance, suggesting flatter, more equitable trajectories. For DKT, ACC SD decreases from 0.0253 (baseline) to 0.0205 (+Features+RL), and AUC SD from 0.0320 to 0.0261. For SAKT, ACC SD drops from 0.0321 to 0.0231, and AUC SD from 0.0396 to 0.0225. This aligns with the design goal: attenuate the early/late performance gap by adapting the reliance on conversational vs. behavioral evidence over time.

5. CONCLUSION AND DISCUSSION

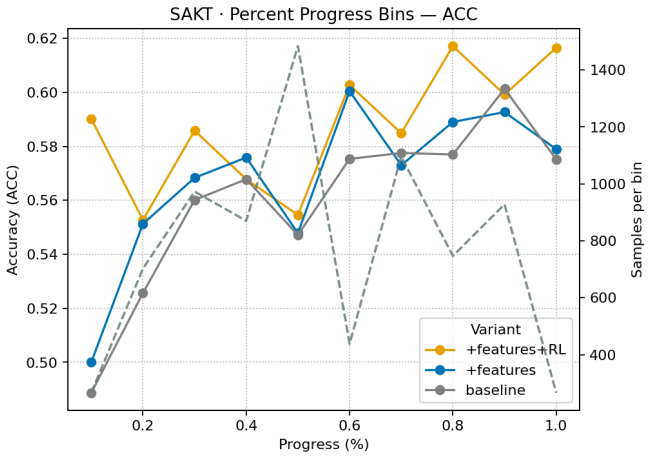


This work examined temporal equity in KT by augmenting behavioral inputs with dialogue-derived features and by learning an adaptive fusion policy via a lightweight RL gate. Under two standard backbones (DKT, SAKT) and a cohorting scheme that groups students by practice volume (10–100% deciles), the RL-gated variant consistently yielded higher aggregate performance (ACC/AUC) and lower dispersion across cohorts, producing flatter cohort-wise curves. Taken together, these results suggest a practical route to reduce performance variability between sparse- and rich-history learners without discarding established KT architectures. At the same time, these findings should be interpreted in relation to prior work on fairness in KT rather than as a standalone fairness claim: prior studies have shown that KT systems can yield inequitable performance across learners and contexts [1], and recent work has explored mitigating such disparities by modifying temporal assumptions within the KT model itself, such as time-augmented BKT [6]. Our results extend this line of work from a different angle. Rather than redesigning the KT backbone itself, we show that a lightweight prediction-stage fusion mechanism can improve reliability when learner histories are sparse while remaining compatible with established KT architectures.

The immediate broader impact of this architecture is therefore not that every legacy ITS can adopt post-problem dialogue features tomorrow, but that it provides a deployable fusion template for settings in which learning evidence extends beyond correctness sequences alone. This is consistent with broader KT research showing that student–item correctness traces often underutilize richer side information such as hints, problem text, or conversational evidence [1]. From a fairness perspective, this also matters because more information does not automatically translate into more equitable modeling; the educational AI literature has repeatedly emphasized that fairness depends on how evidence is represented and used, not merely on whether additional signals are available [5]. In that sense, the present architecture should be read as a practical mechanism for selectively using auxiliary evidence under conditions of evidence scarcity, rather than as a universal retrofit for all KT deployments.



Beyond aggregate metrics, the cohort view offered diagnostic value. We observed that adding dialogue features naïvely (without gating) did not uniformly help—in some cases AUC was unchanged or slightly reduced—indicating that conversational evidence is heterogeneous and history-dependent. This point is important in light of prior fairness work: just as inequities in KT do not disappear automatically through



(a) DKT — AUC (cohort size dashed on right axis)

(b) SAKT — AUC (cohort size dashed on right axis)

(c) DKT — ACC (cohort size dashed on right axis)

(d) SAKT — ACC (cohort size dashed on right axis)

Figure 1: Percent–progress evaluation across learner cohorts formed by student-level practice volume (deciles: 10%, 20%, . . . , 100%). X-axis: cohort by practice volume (10% → 100%). Left Y-axis: performance metric (AUC in panels (a,b); ACC in panels (c,d); range 0–1). Right Y-axis (dashed line): the number of valid prediction samples per bin. (Number of students). Curves compare Baseline, +Features, and +Features+RL; reading them together with the dashed cohort-size trace clarifies reliability under sparse (lower-decile) vs. rich (upper-decile) histories.

model complexity alone [13, 29], our results suggest that they also do not disappear simply by appending more features. Instead, auxiliary conversational evidence appears useful only when it is carefully aligned and selectively weighted. The RL gate appeared to address this by modulating reliance on conversational vs. behavioral signals along the trajectory; early cohorts (where histories are short) tended to benefit more from the additional stream, whereas later cohorts did not require as strong a contribution. In that sense, the equity-aware fusion objective functioned less like a global regularizer and more like a schedule for when and how to use each information source.

We view these findings as pointing to a possible path rather than a definitive solution. In particular, the approach remains intentionally simple: a standard backbone, a compact set of dialogue features (rubric + unit mastery), and a single gating mechanism with a fairness term. This simplicity made the behavior easier to reason about and the gains more attributable, but it also leaves room for complementary improvements (e.g., calibration, per-cohort operating points, or interpretable gating analyses). It also distinguishes our contribution from prior efforts that target fairness by modifying the KT model itself [6]. As such, our study is best interpreted as evidence that adaptive, equity-aware fusion is a viable design principle for KT, not as a claim that any particular architecture is optimal. Accordingly, the present contribution should be read less as a dataset-specific feature recipe and more as a transferable fusion principle for modern tutoring environments that record richer interaction traces than correctness sequences alone [1].

6. LIMITATIONS

First, our dataset contains substantial interaction volume per learner and includes post-problem dialogues from a deployed tutoring setting. This richness likely made it feasible to learn a useful fusion policy: the model could observe enough variation to adjust weights between behavioral

and conversational signals. In contrast, many public KT datasets contain shorter sequences and no conversational channel, which limits how far our specific feature design and gating policy can be generalized as is. We therefore refrained from reporting results on standard public benchmarks that lack comparable signals, to avoid an apples-to-oranges comparison.

Second, our evaluation emphasizes temporal equity through practice-volume cohorts (student-level deciles). Although this targets a practically salient dimension of fairness (supporting learners with limited histories), it is only one slice. We did not analyze demographic fairness, course-level heterogeneity, or domain transfer, nor did we exhaust architectural variants of the gate (e.g., hierarchical or skill-conditional gating). The present results should therefore be read as context-constrained: they demonstrate that equity-aware fusion can stabilize cohort-wise performance on this dataset and setup, but external validity remains to be tested.

In the future, we plan to (i) explore public datasets with sufficient interaction depth or proxied contextual signals (e.g., textual rationales, hint requests) to stress-test the approach beyond our setting; (ii) examine calibration and thresholding per cohort to complement AUC/ACC; (iii) probe the learned gate (feature attributions, skill-conditional patterns) for interpretability; and (iv) evaluate alternative equity objectives (e.g., explicit worst-cohort optimization or variance-constrained training) and more expressive fusion architectures. These steps will clarify when equity-aware fusion provides the largest benefit and how it can be safely adopted in broader KT deployments.

ABSTRACT

Learning to program involves repeated trial-and-error attempts, leading to substantial heterogeneity in learning behavior across student cohorts and course offerings. Code-aware knowledge tracing (KT) models aim to capture how students' programming knowledge evolves over time. However, most existing KT studies rely on data from individual courses, where student interactions are often sparse and insufficient for modeling robust performance patterns. Centralizing student data across classrooms or institutions to address this limitation is often constrained by the risk of privacy breach of sensitive code submission data, limiting the impact of existing KT methods. Federated learning (FL) provides a privacy-preserving alternative by enabling collaborative model training without sharing raw data, and recent work has shown that model personalization can further improve federated KT performance. However, the interaction between model personalization and code representation has not been systematically studied. In this paper, we present a comparative analysis of code-aware KT representations under personalized federated learning (pFL) framework, using two semesters of CodeWorkout data treated as separate clients. Our results show that personalization consistently improves predictive accuracy under federated training, but the magnitude and consistency of these improvements depend on how student code is represented. In particular, code representations that capture richer structural information and syntax-aware encodings exhibit more reliable performance gains and promise more stable learning trajectories across assignments and semesters, especially for more complex programming tasks. These findings provide practical insights for EDM researchers and practitioners on how representation choice shapes the effectiveness of personalization when deploying privacy-preserving knowledge tracing models in programming education.

1. INTRODUCTION

With the growing reliance on learning management systems (LMSs) for the organization and delivery of instructional activities and assessments, time-ordered logs of student interactions with the digital learning environment have become available at scale. Learning analytics leverages these records to track student learning over time, and predict future performance. One prominent approach, known as knowledge tracing (KT) [37], estimates students' latent knowledge states over time and has long been used to uncover learning trajectories, support practice recommendations, and inform adaptive instructional interventions.

Due to their data-driven nature, KT methods benefit from larger and more diverse student interaction datasets, where aggregating student data across courses and semesters enables models to capture nuanced learning behaviors and their evolution over time. However, while such data centralization/pooling can improve model performance through leveraging diverse data, it raises significant privacy concerns. Specifically, regulations like the family educational rights and privacy act (FERPA) [1] restrict student data sharing across institutions to prevent the disclosure of sensitive information. At the same time, while individual/localized training of KT models within a single course avoids these privacy concerns, it often leads to less than optimal performance due to limited data scale and diversity. This limitation is further exacerbated by the nature of student interaction data itself, which is often sparse and unevenly distributed across assignments: some problems receive only a small number of attempts or exhibit limited behavioral variation, constraining the model's ability to learn robust representations of student knowledge and performance, particularly for less frequently attempted or more complex tasks.

Federated learning (FL) has gained traction as a promising distributed machine learning (ML) paradigm to address these challenges [24, 17]. FL allows collaborative model training among multiple data-owning entities, namely *clients*, without requiring the exchange of raw data. Instead, clients train models locally and share only model/gradient parameters with a central server, which aggregates them to form a *global model* that is redistributed for subsequent training

rounds. As a result, by design, FL preserves data privacy while allowing models to benefit from knowledge learned from distributed data sources. In practice, however, data sourced from multiple clients often exhibit substantial heterogeneity - particularly evident in educational domains due to differences in cohort characteristics, instructional methods, or infrastructural contexts. Fairness and correctness considerations being central concerns in education, therefore, makes such one-size-fits-all models less effective. To address this issue, recent work has explored *personalization* strategies in FL, which adapt the global model to client-specific data and have been shown to improve both predictive performance and fairness. As a result, FL with personalization has attracted growing attention in educational applications [3, 33, 35, 14, 21, 13, 22, 43, 39], particularly for tasks such as KT [41, 5, 6].

Yet, programming education introduces unique challenges for KT in FL or simply, *federated KT*. Specifically, as learning happens through iterative code submissions to open-ended programming problems, student-generated code serves as the primary sequential evidence of learning progress, making code representation a central factor in modeling student knowledge. To cater to such distinct needs in programming education, KT models are, therefore, often code-aware, incorporating representations of student code submissions to better capture learning processes. However, while personalized federated KT has been studied, the interaction between code representation choices and personalization of federated models remains underexplored. In particular, it is unclear how different code-aware KT models behave under federated training, and how personalization impacts representation-specific strengths and weaknesses of the model. To address this gap, this paper investigates how code representation shapes the behavior and performance of code-aware KT models trained under personalized federated learning (pFL).

1.1 Research Questions

We extend three code-aware KT models: Code-DKT [38], SANN-DKT [12], and srcML-DKT [27], to FL settings to enable privacy-preserving performance prediction across semesters. To account for cross-semester heterogeneity, we incorporate pFL strategies and empirically analyze their effects across different code representations. To our knowledge, this work is the first study that employs pFL on code representation to provide data privacy and better predictive modeling for code-aware KT methods. The summary of our contributions lies in the answers to the following questions:

RQ1: Do relative performance differences arising from code representation choices in KT models persist under privacy-preserving pFL?

RQ2: To what extent does the personalization aspect of pFL impact cross-semester prediction accuracy in code-aware KT?

2. RELATED WORK

2.1 Modeling Student Learning with KT

Prior work has shown that students engage with programming practice systems in distinct ways, exhibiting varied behavioral patterns such as exploration and persistence [30]. At the same time, programming learning involves mastering a set of underlying skills or knowledge components (KCs) that are reflected across exercises and instructional materials [40]. Understanding how these behaviors relate to the acquisition and application of knowledge over time has been a central focus of learning analytics [37], motivating the development of knowledge tracing (KT) models. Early KT models were probabilistic, most notably Bayesian Knowledge Tracing (BKT) [8], which represents learning as a hidden Markov process and estimates the probability that a student has mastered a skill as they engage with successive tasks. Extensions of BKT introduced individualized parameters to account for variation in prior knowledge and learning rates across students [44]. Related approaches, such as Performance Factors Analysis (PFA) [28] and Learning Factors Analysis (LFA) [4], used logistic regression over prior successes and failures to estimate knowledge states. While influential, these models struggle to capture complex learning dynamics involving multiple interdependent skills and individualized learning trajectories.

The introduction of deep learning marked a major shift in knowledge tracing research. Deep Knowledge Tracing (DKT) [29] showed that recurrent neural networks can capture temporal patterns in student behavior better, leading to notable gains in predictive accuracy. Subsequent work built on this idea by incorporating memory mechanisms, attention, and richer representations. Examples include Dynamic Key-Value Memory Networks (DKVMN) [47] and Self-Attentive Knowledge Tracing (SAKT) [26], as well as later models that combine multiple architectural components to improve scalability and performance [32, 31, 18]. More recent approaches have further expanded the KT landscape by introducing relational and contrastive perspectives, such as graph-based and problem-solving–oriented models [25, 42, 16, 48]. Together, these advances have substantially improved the modeling of student learning behavior.

2.2 Potential of pFL in Code-aware KT

While KT has been effective in many educational settings, open-ended programming courses pose distinct challenges. In such courses, learners often submit multiple iterations of source code, and correctness alone provides only a partial signal of learning. Each attempt contains structural and semantic details that reflects how students reason about problems, debug errors, and refine their solutions over time. The emergence of code-aware KT models prompted moving beyond just correctness labels by explicitly modeling student code. Code-DKT uses transformed code embeddings to represent semantic details of student submissions [38], while SANN-DKT applies attention mechanism to emphasize code parts that contribute most to prediction [12]. srcML-DKT takes this further by allowing incomplete or buggy codeblocks to incorporate syntactic and semantic evolution of student code [27]. Collectively, these studies demonstrate that incorporating structural, semantic, and contextual information from code leads to a more nuanced and fine-grained understanding of programming knowledge acquisition. Additional work has explored alternative representations and objectives, including error-based features for capturing misconceptions (Error-DKT)[36], explainable KT models providing cognitive feedback (HELP-DKT)[23], methods that improve interpretability through automatically generated knowledge components (KCGen-KT)[9] or knowledge graphs (KGNN-KT)[45], and question-centered

approaches that incorporate student-generated questions to support generalization (SQKT)[19].

As efforts to improve KT in programming education continue, they also reveal a key limitation: code-aware KT models typically require large and diverse datasets to perform reliably. In practice, data from a single course or semester are often insufficient, motivating the aggregation of student interaction and code data across offerings or institutions. However, such data centralization/pooling, especially raw code submissions, raises serious privacy concerns and is frequently restricted by institutional policies and regulations. FL has therefore emerged as a promising alternative, enabling collaborative model training without sharing raw data [24]. Prior work has explored federated KT in domain-generic contexts, showing that pFL can improve performance and fairness across heterogeneous clients [41, 5, 6]. However, the interaction between domain-specific code representation and pFL remains largely understudied. Specifically, existing federated KT methods do not examine how different code-aware representations behave under federated training, nor whether personalization impacts their accuracy. To address this gap, our work systematically studies how different code-aware KT representations respond to pFL, providing insights into predictive performance across decentralized programming education settings.

3. METHODOLOGY

3.1 Datasets

In this study, we will analyze two datasets from CodeWorkout, an online platform to practice Java programming.[1] The platform allows instructors to design and deliver programming courses, while providing students with the opportunity to complete exercises and receive immediate feedback [10]. CodeWorkout records detailed logs of student submissions, with scores assigned based on the number of test cases passed. Students may submit multiple solutions for the same problem, allowing us to get chronological updates of their iterative problem-solving processes. The evaluation of student knowledge in these datasets spans a range of programming concepts, including method declarations, loops, arrays, arithmetic operations, logical expressions, data types, conditionals, and nested conditional statements.

Table 1: Dataset details

Semester	Students	Attempts	Compilable	Correct	Incorrect
Spring 19	258	131203	45096	10343	34753
Fall 19	506	360176	125578	24680	100898

Upon its use in an introductory programming (CS1) course at a public university in the United States during the Spring 2019 and Fall 2019 semesters, two datasets were formed containing anonymized submissions for 50 programming problems across five assignments `caughtSpeeding, redTicket, countCode, sum13, and canBalance`) and no accompanying demographic information. [2] We obtained these publicly available datasets from DataShop [20]. Each submission was graded on a continuous scale from 0 to 1 based on the proportion of test cases passed, and for modeling purposes, we categorized the outcomes into binary groups: correct (scored 1 out of 1) and incorrect submissions (failing at least one test case resulted in a 0). Table 1 shows details of the Spring 2019 and Fall 2019 datasets. We split each dataset into training, validation, and test sets in a stratified manner to account for class imbalance, using a 80:10:10 ratio.

[2]https://pslcdatashop.web.cmu.edu/Files?datasetId=3458

3.2 KT Formulation

For knowledge tracing, we use deep knowledge tracing (DKT), a well-established model that along with its variants has performed reasonably well when applied on the CodeWorkout dataset [38]. In DKT formulation, a student's learning history is represented as a sequence of attempts $\{x_1, x_2, \ldots, x_T\}$, where each attempt x_t at time step t corresponds to a problem-correctness pair (q_t, a_t). Here, $q_t \in \{1, 2, 3, \ldots, M\}$ denotes the problem identifier for M total problems and a_t can be 0 or 1, indicating incorrectness and correctness, respectively. Each interaction is one-hot encoded as a binary vector $x_t \in \{0, 1\}^{2M}$, where $x_{q_t+M(1-a_t)}$ is considered 1, and the rest of the entries are set to 0. In code-aware DKT methods, each interaction is additionally associated with a code representation z_t, extracted from the student's submitted programs. They are further transformed into vectorized code representations $\{z_1, z_2, \ldots, z_T\}$, which are concatenated with interaction embedding to form an augmented input vector $[x_t; z_t]$, as shown in Figure 1. These inputs are processed sequentially by a long short-term memory (LSTM) model that maintains an internal memory state to capture both short- and long-term temporal dependencies across attempts. The LSTM hidden state provides a latent representation of the student's knowledge and is updated after each interaction. Starting with h_0 that represents the model's belief about the student's knowledge before seeing any data, h_t tracks the evolving knowledge of the student across time t, which can be expressed as $h_t = \text{LSTM}([x_t; z_t], h_{t-1})$, where $x_t = \text{embedding}(q_t, a_t)$. At each time step t, the model outputs a vector of predicted correctness probabilities over all problems $\{y_1, y_2, \ldots, y_T\}$, where each entry denotes the predicted likelihood that the student will answer the corresponding problem correctly. The predicted correctness for the next interaction, a_{t+1}, is obtained by selecting the entry of y_t associated with the next attempted problem q_{t+1}, which is used for performance prediction.

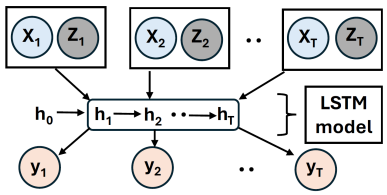

Figure 1: Schematic diagram of code-aware DKT. Across T timesteps, each interaction at t is a concatenation of problem-correctness encoding x_t and student code vector z_t, which are processed sequentially along with latent hidden state h_t to predict correctness probabilities y_t for future attempts.

3.3 FL Framework

The vanilla **Federated Averaging (FedAvg)** algorithm [24], combined separately with each of the three KT techniques, is used as the set of baseline methods in this work. This architecture is presented within the blue box in Figure 2, where,

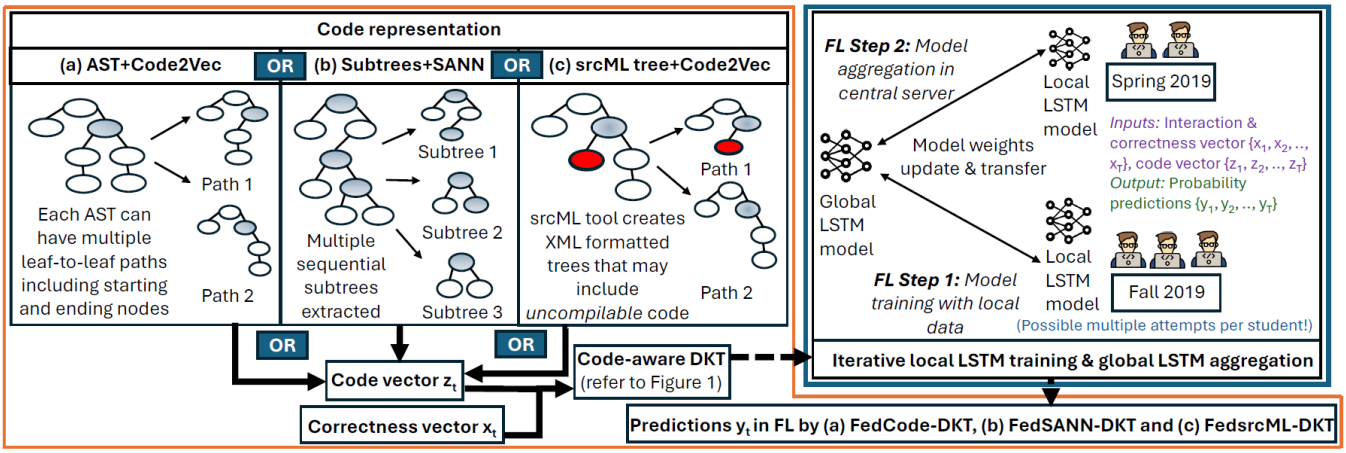

Figure 2: Detailed pipeline of code-aware DKT with FL: orange box contains the entire architecture while blue box shows FL framework. Three code representation strategies are considered. In (a) and (c), gray nodes illustrate how code paths are constructed from an abstract syntax tree by Code2Vec, whereas red nodes in (c) indicate uncompilable code blocks captured by srcML. In (b), subtrees are extracted by SANN from the AST based on gray nodes. Student code submissions are transformed into fixed-length vectors z_t, concatenated with correctness vectors x_t and used to train semester-specific LSTM-based DKT models locally. Model parameters are then aggregated via FedAvg to form separate federated models that predict the probability of future student attempts across semesters y_t.

data from academic semesters are treated as belonging to distinct *clients*, reflecting a realistic scenario, where student interaction data are sourced from different course offerings.

A central server coordinates the federated training process across these clients through iterative rounds of local training and global aggregation. Let K denote the number of clients (semesters), and let $\mathcal{D}_k$ represent the dataset associated with client k, with size $n_k = |\mathcal{D}_k|$. To start each global aggregation τ, the server broadcasts the current global model parameters $\theta^{(\tau)}$ to all clients. Each client initializes its local model with these parameters $\theta_k^{(\tau),0} \leftarrow \theta^{(\tau)}$ and performs local stochastic gradient descent (SGD) updates on mini-batches sampled from its own dataset. Specifically, during each global aggregation τ, client k updates its local parameters by minimizing the empirical loss function ℓ for $e_{\max}$ local SGD steps, where the final local model is:

$$\theta_k^{(\tau+1)} \leftarrow \theta^{(\tau)} - \alpha \sum_{i=0}^{e_{\max}-1} \nabla \ell\big(\theta_k^{(\tau),i}, \mathcal{B}_k^{(\tau),i}\big), \tag{1}$$

where α denotes the learning rate and $\mathcal{B}_k^{(\tau),i}$ represents a mini-batch of size B sampled from client k's data at SGD iteration i. Subsequently, the client sends $\theta_k^{(\tau+1)}$ to the server, and the server aggregates the local models using weighted averaging to obtain the next global model as follows:

$$\theta^{(\tau+1)} = \sum_{k=1}^{K} \frac{n_k}{\sum_{k'=1}^{K} n_{k'}} \theta_k^{(\tau+1)}. \tag{2}$$

The resulting global model $\theta^{(\tau+1)}$ is then reshared with all clients to initiate the next training round. In our experiments, this federated optimization process is repeated for a total of $\mathcal{T} = 10$ global rounds (i.e., $\tau \in \{0, \cdots, 9\}$). All remaining FL hyperparameters are selected via grid search, with learning rates $\alpha \in \{0.001, 0.005\}$, mini-batch sizes $B \in \{128, 256\}$, and the number of local training steps $e_{\max} \in \{20, 40\}$.

We next apply this FL framework to three code-aware KT models, yielding the novel FedCode-DKT, FedSANN-DKT, and FedsrcML-DKT models, which are discussed below.

3.3.1 *FedCode-DKT*

Code-DKT builds upon the original DKT framework by augmenting the problem-correctness interaction x_t with a code representation z_t derived from the student's attempt logged, enabling the model to leverage information beyond binary correctness [38]. As illustrated in Figure 2(a), each code submission at time t is transformed into an abstract syntax tree (AST), which serves as the basis for extracting the corresponding code representation z_t. Code-DKT employs `Code2Vec` [2], a neural model embeds leaf-to-leaf paths in the AST, to transform ASTs into embedded vectors ready to be used for any ML model. Code2Vec is originally designed to predict Java method names, and its internal representations can be retrieved as code embeddings, providing a compact vectorized representation of the underlying program structure. Using separate node and path embedding layers, embeddings for each of the paths are generated as vectors. These vectors are then fed into the attention layer, where the correctness score x_t determines which path is important for the final prediction. Following softmax activation and concatenation of weighted sum, the aggregated vector of correctness probabilities is generated as the output z_t of the linear layer. Once the vectors are formed for the entire dataset for reported timestamps $1, 2, 3, \ldots, T$, they are fed as inputs to respective LSTM models (identified by semesters) along with the correctness scores for all T attempts. Each semester is locally trained with their respective data, where the global model is updated with the aggregated local model parameters. After a back-and-forth transfer for 10 iterations, the federated model outputs prediction probabilities.

3.3.2 *FedSANN-DKT*

SANN-DKT introduces a self-attention-based code representation strategy to highlight critical portions of the source

code that are most indicative of future performance [12]. It employs *subtree-based attention neural network (SANN)* [11] instead of ASTs, as demonstrated in Figure 2(b). Under the SANN framework, a single code submission is decomposed into a set of *node-specific, order-preserving subtrees* generated via depth-first, preorder traversal. Each subtree corresponds to a semantically meaningful code fragment, such as loops, conditional blocks, or method invocations. These subtrees are transformed into vector representations through two complementary embedding operations: *node embeddings*, which encode individual nodes within a subtree, and *subtree embeddings*, which capture subtree-level structural information. The node embeddings within each subtree are first aggregated, and the resulting vector is concatenated with the corresponding subtree embedding to form a unified subtree representation. The resulting set of subtree vectors is then passed through an attention mechanism that assigns higher weights to code fragments most informative of a student's understanding or programming concepts. The aggregated representation of weighted subtrees is originally fed into a neural network for classification, predicting whether a student is likely to succeed or struggle. In this work, however, we do not employ SANN in an end-to-end classification setting. Instead, we extract the intermediate code representations z_t produced by the fully connected layer following the attention mechanism and softmax normalization, and use these vectors along with correctness vector x_t as inputs to the LSTM model. *It is to be noted here that unlike Code2Vec, which is a pretrained encoding model, SANN directly learns from the same client populations that participate in federated training for knowledge tracing.* Therefore, to ensure that the resulting code representations reflect cohort-specific characteristics, we federate the SANN pipeline itself with the client data before the rest of the FL pipeline is combined.

3.3.3 FedsrcML-DKT

srcML-DKT extends this line of work by adopting `srcML` as the underlying code representation, enabling the modeling of *uncompilable* code submissions and thereby capturing syntactic errors that arise as students iteratively refine their solutions [27]. By replacing AST-based representations with srcML, as shown in Figure 2(c), this framework can parse code fragments that fail to compile and convert them into XML-based structures [7]. These representations can encode both syntactically correct and incorrect code by wrapping source text within XML tags that describe structural elements, while preserving erroneous or incomplete constructs textually. As a result, srcML-DKT incorporates *all* student submissions, rather than discarding non-compilable attempts. Following a pipeline analogous to Code2Vec, the srcML representations are subsequently transformed into fixed-length vector embeddings z_t, which are then provided as inputs, along with correctness vector x_t, to the LSTM-based KT model in FL setting. This design allows to model the evolution of student coding strategies across attempts while maintaining data privacy and retaining fine-grained syntactic information, even in the presence of compile errors.

3.4 Personalization of FL Models via pFL

Although both datasets originate from the same CS1 course and share identical feature definitions, the two semesters correspond to different student cohorts. Variations in prior experience, learning pace, and coding behavior lead to systematic shifts in interaction patterns and code structures, resulting in non-IID feature distributions across semesters, confirmed by statistically significant differences in a Kolmogorov–Smirnov (KS) test. Under such cohort-induced heterogeneity, a single global federated model may not perform uniformly across semesters, motivating the use of pFL to adapt to local data distributions. We adopted **Federated Adaptive Local Aggregation (FedALA)** [46], a pFL approach that extends vanilla FedAvg by introducing a personalized model synchronization mechanism at each client, as shown in Figure 3. This choice is motivated by FedALA's superior capability of sufficiently adapting to local settings than simple post-hoc fine-tuning of the federated model [13].

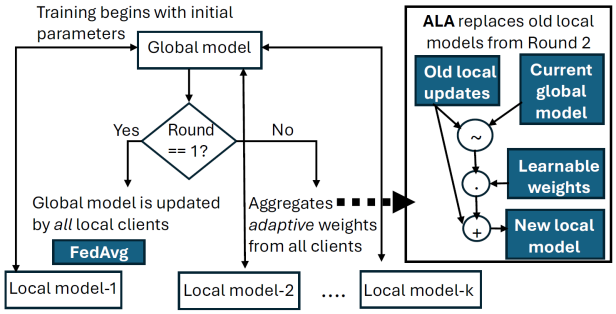

Figure 3: FedALA applies personalization on FedAvg.

While local training and global aggregation follow the standard FedAvg procedure, FedALA replaces direct overwriting of local models with an *adaptive local aggregation* (ALA) step. Let $\theta^{(\tau)}$ denote the global model parameters broadcast by the server at global aggregation round τ, and let $\theta_k^{(\tau-1)}$ denote the final local model parameters of client k obtained at the end of the previous round. Rather than initializing the local model as $\theta_k^{(\tau),0} \leftarrow \theta^{(\tau)}$, FedALA initializes the local parameters by adaptively combining the previous local model with the received global model:

$$\theta_k^{(\tau),0} = \theta_k^{(\tau-1)} + \left(\theta^{(\tau)} - \theta_k^{(\tau-1)}\right) \odot \lambda_k, \tag{3}$$

where λ_k is a learnable, element-wise aggregation weight matrix constrained to the interval $[0, 1]$, and $\odot$ denotes element-wise multiplication. Instead of initializing the local model with the received global model, this adaptive aggregation allows each client to selectively incorporate globally shared information while suppressing updates that are less relevant to its local data distribution. FedALA further exploits the hierarchical structure of deep neural networks by applying adaptive aggregation only to the top l layers of the model, while the remaining lower layers (assumed to encode more general representations) are directly inherited from the global model without modification. FedALA learns λ_k using a fraction ζ of each client's local dataset. This design balances global knowledge sharing with client-specific adaptation. We tune the FedALA hyperparameters through grid search, with $l \in \{1, 2\}$ and $\zeta \in [5, 100]$ with increments of 5.

4. RESULTS & DISCUSSIONS

To evaluate the prediction task, we considered all student attempts across five programming assignments (*A1-A5*) and addressed our two research questions (RQ), described below.

We measure predictive performance using area under curve (AUC): as programming datasets are highly imbalanced, AUC is more informative than accuracy, with 0.5 indicating random prediction and 1 indicating perfect discrimination. To answer RQ2, in addition to embedding-based representations, we report results for a non-embedding TF-IDF [34] method that represents code as weighted word-frequency vectors capturing surface-level patterns only.

RQ1: What does federated code representation performance difference mean in code-aware KT model performance? Figure 4 shows assignment-level AUC differences between Code-DKT and SANN-DKT and srcML-DKT and SANN-DKT under individual (i.e., sole local training) and federated settings, where positive values indicate higher AUC for SANN-DKT framework. As a reference, we used results reported by Hoq et al.[12] on Spring 2019 dataset, and examined whether SANN-DKT outperforming Code-DKT remains consistent under privacy-preserving FL. We replicated the same analysis on Fall 2019 dataset and the rank persisted. Further, we also implemented srcML-DKT and observed srcML-DKT performing better than SANN-DKT in most cases. Our results in Figure 4 top row indicate that FedSANN-DKT largely retains its code representation-driven performance advantage over FedCode-DKT, achieving significantly higher AUC values, confirmed by a paired Wilcoxon signed-rank test ($p < 0.05$). Bottom row indicates similar outcomes between FedsrcML-DKT and FedSANN-DKT, further demonstrating that FL does not fundamentally disrupt the performance advantages conferred by richer code representations. However, this phenomenon is not uniform across all assignments. We observe small, assignment-specific reversals in relative performance, primarily on simpler tasks where overall AUC is already high and solution strategies exhibit limited structural diversity. This effect is most evident for A1 in top-left subfigure, where near-saturated performance constrains the marginal benefit of SANN's neighborhood-based structural encoding over simpler path-based representations, making model rankings more sensitive to cohort-induced variation amplified through federated aggregation. In contrast, as assignments become conceptually more complex (A2–A5), and understanding code organization (i.e., combining multiple constructs and managing program control flow) is critical, representations that explicitly encode program structure more frequently outperform simpler path-based encodings under federated setting, resulting in $AUC_{FedSANN-DKT} > AUC_{FedCode-DKT}$. This pattern is consistent with the performance hierarchy reported in individual training settings [12], unveiling that FL tends to preserve code representation rank with observed variations influenced by task complexity and data sparsity. These findings motivate a closer examination of how personalization interacts with representation choice under FL, which we investigate next in the context of RQ2.

RQ2: How does model personalization affect federated code representation across semesters/clients? Personalization via FedALA substantially improves cross-semester predictive accuracy in all *code-aware* federated KT models, with gains varying by assignment difficulty and code representation, as shown in Figure 5. Although TF-IDF is not a focus of our method, its inclusion here underscores that personalization by itself is insufficient; meaningful and consistent improvements in federated settings emerge primarily when personalization

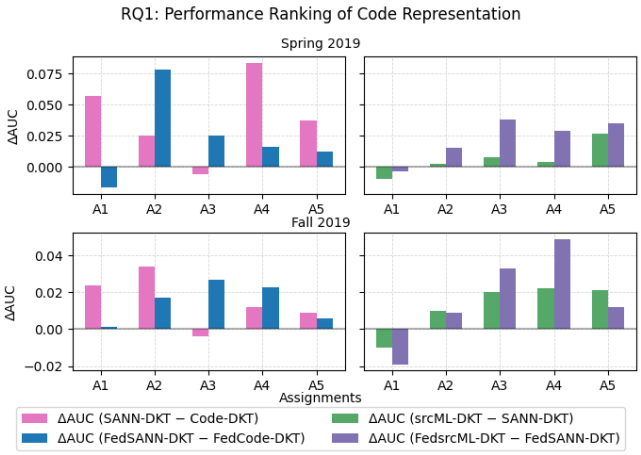

Figure 4: Performance gains ($AUC_{SANN-DKT} > AUC_{Code-DKT}$ [12]) are largely preserved in FL for Spring 2019 (small flips occur on simpler assignments where differences are tiny). Similar results are obtained in other cases.

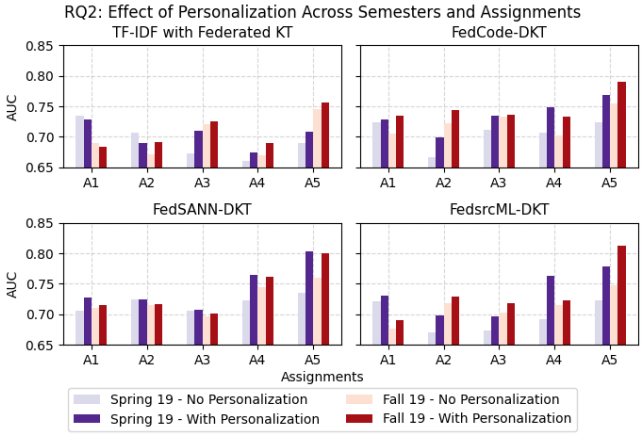

Figure 5: Though personalization impact on no-embedding technique TF-IDF was not reliably determined, personalization of FedCode-DKT, FedSANN-DKT and FedsrcML-DKT significantly outperform their baseline FL counterparts based on AUC differences (mean standard deviations: 0.0015, 0.008 and 0.0012, respectively) across semesters and assignments.

operates over embedding-based, code-aware representations. In contrast, embedding-based approaches show larger and more consistent personalization gains, with FedCode-DKT and FedSANN-DKT exhibiting improved alignment across semesters, particularly on later assignments. The effect is most pronounced for FedsrcML-DKT, where personalization leads to substantial and stable gains on structurally complex assignments (A4–A5) and reduces cross-semester performance gaps. A paired t-test shows that these sets of improvements achieved by FedALA over FedAvg are statistically significant ($p < 0.05$). These results suggest that though improvement magnitude varies based on task complexity, personalization does not degrade performance, instead it has the potential to better adapt to cohort-specific patterns in code-aware KT, while preserving privacy.

5. IMPLICATIONS FOR EDM & LIMITATIONS

Informed by our findings, personalized federated model generates actionable insights that instructors can use to identify students who may be struggling early in a privacy-preserving manner, particularly those showing repeated errors or inefficient coding patterns. These patterns reflect how students iteratively refine their problem-solving strategies over time through repeated attempts, errors, and code revisions.

However, two limitations should be noted despite promising results. First, our analysis is based on a single programming language Java. Since programming languages differ in syntax and structure, the observed performance trends may not generalize directly to other contexts such as Python or C++. Second, we model FL using two semesters of the same course from one institution. While there are some cohort differences, the overall learning environment remains similar. This limits the level of data heterogeneity compared to real-world federated settings that involve multiple institutions and more diverse student populations. Consequently, the extent to which the model performs consistently across diverse learner groups remains an open question. The close connection between fairness and model usefulness in human-centered applications [15] highlights the need for future evaluations on more diverse, cross-institutional datasets beyond predictive performance alone.

6. CONCLUSION & FUTURE WORK

In this paper, we studied how different code-aware knowledge tracing (KT) models behave under federated learning (FL), with a particular focus on code representation and model personalization. To this end, we present the first integration of personalized FL (pFL) with code embedding methods as an initial step toward privacy-preserving student code modeling and improved performance prediction. Using semester-level federated training on programming course data, we show that code representation type continues to influence predictive performance under FL, which pFL can further improve besides reducing cross-semester performance disparities through semester-specific adaptation. *From a pedagogical perspective, this framework enables equitable and privacy-preserving instructional support regarding code-level misunderstanding.* Our findings also indicate that retaining uncompilable code and incomplete attempts, which reflect authentic learning processes, leads to the strongest performance among the evaluated representations in pFL settings.

A key challenge in programming education datasets is the prevalence of incorrect submissions relative to correct ones, making it difficult for models to learn from the relatively few correct attempts. This limitation motivates future exploration of federated few-shot learning method to ensure that infrequent but informative demonstrations of understanding are not overlooked. Further, we plan to include features derived from student and system engagement data in our analysis, which our preliminary explorations suggest may capture insights of both coding and learning behavior. *In practice, this will allow instructors to distinguish between students who struggle conceptually and those who are actively engaging but iterating through errors only, enabling more targeted instructional support.* While our study focuses on a limited set of representations and course offerings, it highlights key design considerations for deploying privacy-preserving learning analytics in programming education, and motivates future research on representation-aware federated KT with programming-specific modeling choices, broader datasets, and richer FL personalization strategies.

ABSTRACT

Automated short answer grading (ASAG) is critical for scaling educational assessment, yet large language models (LLMs) often struggle with hallucinations and strict rubric adherence due to a mismatch between generalized pre-training objectives and the task-specific requirements of grading. While Retrieval-Augmented Generation (RAG) can reduce hallucinations by providing access to relevant reference materials, standard flat vector retrieval treats knowledge as isolated fragments, failing to capture the structural relationships and multi-hop dependencies inherent in complex educational content. To explore whether incorporating structural information is beneficial for ASAG, we investigate Graph Retrieval-Augmented Generation (GraphRAG) as a general paradigm and systematically evaluate two representative instantiations, Microsoft GraphRAG and HippoRAG, on this task. These approaches differ in how they construct and traverse knowledge graphs, providing complementary perspectives on graph-based evidence retrieval. Experimental evaluations on a Next Generation Science Standards (NGSS) dataset demonstrate that structural retrieval outperforms standard RAG baselines across all metrics. Notably, the HippoRAG achieved substantial improvements in evaluating Science and Engineering Practices (SEP), confirming the superiority of structural retrieval in verifying the logical reasoning chains required for higher-order academic assessment.

Keywords

Large Language Model, Automated Grading,
Retrieval-Augmented Generation (RAG), GraphRAG

1. INTRODUCTION

Automated short answer grading (ASAG) has emerged as a critical technology for scaling educational assessment, aiming to evaluate student responses with the same accuracy and consistency as human instructors. While early approaches relied on keyword matching and latent semantic analysis, the advent of large language models (LLMs) has fundamentally transformed the landscape. LLMs possess remarkable semantic understanding and generation capabilities. These features allow them to not only interpret complex student answers but also, crucially, to understand and adhere to nuanced grading rubrics with human-level flexibility. However, despite their fluency, off-the-shelf LLMs frequently struggle with the strict constraints of academic grading. They are prone to "hallucinations" where plausible but incorrect justifications are generated. Furthermore, they often fail to adhere strictly to specific grading rubrics, relying instead on their generalized internal knowledge acquired during pre-training. This vast but generic training data often conflicts with specific course definitions or omits the precise constraints required by a local curriculum. To mitigate these limitations, recent works have integrated retrieval-augmented generation (RAG) into the grading pipeline. A prominent example of this advancement is the system proposed by Chu et al., which enhances LLM grading by grounding the model's decisions in a specific knowledge base [1]. Their approach constructs a repository of reference answers and scoring criteria, utilizing a dual retrieval strategy to fetch the most relevant grading standards for a given student response. By dynamically providing the LLM with the exact rubric criteria needed for a specific question, this RAG-based method significantly reduces hallucination and improves the alignment between automated scores and human judgment. The system effectively converts the grading task from an open-ended generation problem into a grounded reasoning task, where the model must support its evaluation with retrieved evidence.

Despite the improvements offered by standard RAG frameworks, important technical limitations remain when they are applied to complex educational content. Standard RAG systems typically rely on vector similarity search, which encodes text into high-dimensional semantic embeddings and retrieves chunks of information that are semantically related to the query. This flat retrieval method is widely adopted because it is simple and efficient. However, it treats knowledge as isolated fragments and does not explicitly represent the structural relationships among concepts, criteria, and examples. A key issue in ASAG is not only whether a relevant rubric chunk can be retrieved, but whether the retrieved ev-

idence preserves the relational structure needed to evaluate a student's reasoning. For example, a rubric may describe a correct explanation using formal scientific terminology, such as "enzymatic denaturation leading to substrate-binding failure," while a student may write that "the enzyme stops working because heat changes its shape." A reference-anchored flat-RAG query can help retrieve the formal rubric language, and a student-anchored query can retrieve passages related to heat or reaction failure. However, both approaches still return independent text chunks rather than an explicit path connecting heat, structural change, binding failure, and reaction outcome. The grader must then infer the missing relationships from fragmented evidence. This context fragmentation can degrade automated grading, especially when the scoring decision depends on whether a student has connected multiple ideas in a scientifically valid way. When retrieval provides isolated facts but not their dependencies, the LLM may still rely on its pre-trained knowledge to infer the relationship among them. This reintroduces the risk of hallucination or inconsistent rubric adherence, even when some relevant text has been retrieved.

To address the inability of flat retrieval systems to capture deep semantic structure, this work introduces a novel grading framework based on graph retrieval-augmented generation (GraphRAG) [5]. Unlike standard RAG, which indexes information as independent vectors, GraphRAG organizes the reference material and grading rubrics into a structured *knowledge graph* (KG). In this architecture, specific concepts, criteria, and keywords act as nodes, while the logical relationships between them, such as hierarchy, causality, and prerequisites, are represented as edges. This graph-based structure allows the system to move beyond simple similarity matching. When evaluating a student's answer, our system does not merely fetch isolated text chunks; it traverses the knowledge graph to retrieve a connected subgraph of information. This enables the retrieval of "multi-hop" evidence, where the system can identify that concept A is relevant to the student's answer because it is causally linked to concept B, even if concept A was not explicitly mentioned in the initial query. By preserving the relational context of the reference material, our approach provides the LLM with a holistic view of the grading criteria, rather than fragmented snapshots. Our method is particularly advantageous for questions requiring higher-order thinking, where the correctness of an answer depends on the synthesis of multiple concepts. The following sections detail the construction of the grading knowledge graph, the graph traversal algorithms employed during the grading phase, and the comparative experimental results. Our evaluations on Next Generation Science Standards (NGSS) tasks demonstrate that this structural retrieval approach significantly outperforms standard RAG baselines, with the HippoRAG architecture achieving particularly substantial improvements in verifying the logical reasoning chains required for Science and Engineering Practices.

2. RELATED WORK

The development of automated short answer grading (ASAG) has evolved from simple lexical matching to complex semantic reasoning systems. This section reviews the historical progression of grading technologies, the recent integration of retrieval-augmented generation (RAG) to address hallucination, and the emerging paradigm of graph-based retrieval which forms the technical foundation of this work.

2.1 Automated Short Answer Grading

Early approaches to ASAG relied heavily on statistical and keyword-based methods. Techniques such as latent semantic analysis (LSA) and unigram overlap were employed to measure the similarity between a student's response and a reference answer [4, 7]. While computationally efficient, these methods operated on a "bag-of-words" assumption, ignoring word order and syntactic structure, which often led to the misclassification of answers that used correct terminology in incorrect contexts. The field advanced significantly with the introduction of pre-trained language models (PLMs) such as BERT. These models utilized self-attention mechanisms to capture contextual nuances, allowing for more accurate semantic matching. However, BERT-based systems were primarily discriminative, treating grading as a classification task (correct vs. incorrect) rather than generating interpretable feedback. The advent of large language models (LLMs) shifted the paradigm towards generative grading, where models could both score an answer and provide a justification. Despite this capability, generative LLMs suffer from a lack of domain specificity and a tendency to hallucinate, fabricating plausible but factually incorrect reasoning when the model's internal knowledge conflicts with specific course rubrics.

2.2 RAG in Education

To mitigate the hallucination and context limitations of off-the-shelf LLMs, researchers began adopting RAG [3]. RAG systems decouple the model's reasoning capabilities from its knowledge storage by retrieving relevant documents from an external corpus and injecting them into the model's context window. This approach is particularly vital in educational settings where grading criteria are rigid and course-specific. The work of Chu et al. represents the state-of-the-art in this domain [1]. Their system utilizes a dense vector retrieval mechanism to fetch specific reference answers and scoring rubrics relevant to a student's query. By grounding the LLM's generation in these retrieved artifacts, they successfully demonstrated a reduction in grading errors and improved alignment with human evaluators. However, standard RAG systems, including the one proposed by Chu et al., rely on "flat" retrieval strategies. They chunk documents into independent text segments and retrieve them based on vector similarity. This process treats knowledge as isolated fragments, often failing to retrieve information that is conceptually related but not explicitly similar in vector space, such as multi-step causal chains or hierarchical dependencies essential for grading complex questions.

2.3 GraphRAG

Graph retrieval-augmented generation (GraphRAG) has emerged as a solution to the limitations of flat retrieval by introducing structural awareness into the generation pipeline [6]. Unlike standard RAG, which views data as an unstructured collection of text chunks, GraphRAG organizes information into a knowledge graph (KG), where entities (concepts) are nodes and relationships (dependencies, causality) are edges. Microsoft Research's recent implementation of GraphRAG demonstrates that traversing these graph

structures allows LLMs to perform "global" reasoning over a dataset, connecting disparate pieces of information that standard vector search would miss [2]. In the context of grading, this allows a system to recognize that a student's answer regarding a specific biological function is correct not just because it matches a keyword, but because it correctly identifies the prerequisite process defined in the knowledge graph. By traversing the edges of the graph, the retrieval module can fetch a subgraph containing the question, the direct answer, and the underlying principles, providing the LLM with a structurally complete context for evaluation.

3. PROBLEM STATEMENT

While the integration of retrieval-augmented generation (RAG) into grading pipelines has significantly reduced the incidence of hallucination, current state-of-the-art systems remain constrained by their underlying retrieval mechanisms. The fundamental limitation lies in the mismatch between the "flat" data representation used by standard vector retrievers and the highly structured, relational nature of educational knowledge.

3.1 Limitations of Flat Vector Retrieval

Standard RAG systems, including the baseline framework proposed by Chu et al. [1], operate on the principle of semantic similarity matching. In this paradigm, the grading rubric and reference materials are segmented into discrete text chunks, $D = \{d_1, d_2, ..., d_n\}$, which are then encoded into high-dimensional vector embeddings. Given a student's answer as a query q, the system retrieves a subset of chunks based on a similarity metric, such as cosine similarity, expressed as $Score(q, d_i) = \cos(\mathbf{v}_q, \mathbf{v}_{d_i})$.

This approach relies on the assumption that the necessary grading criteria are semantically proximate to the student's answer in vector space. However, this assumption frequently fails in educational contexts where concepts are linked by logical dependencies rather than mere lexical overlap. A student's response might correctly discuss a downstream effect (concept C) of a biological process (concept A) without explicitly mentioning the intermediate mechanism (concept B). A flat retriever, searching for terms related to A and C, is likely to retrieve chunks containing only A or C. It often fails to retrieve the bridging chunk containing concept B because B is not semantically similar enough to a query embedding constructed from A and C. Consequently, the LLM is presented with fragmented evidence so that it knows the cause and the effect but misses the crucial explanatory link required to verify the student's reasoning.

3.2 The Challenge of Multi-Hop Reasoning

The core deficiency of flat retrieval in automated short answer grading is the inability to support multi-hop reasoning. Academic grading often requires verifying a chain of logic: verifying that a student understands that $X \rightarrow Y \rightarrow Z$. In a standard vector store, the relationship $X \rightarrow Y$ and $Y \rightarrow Z$ may reside in separate, non-adjacent chunks. To quantify the necessity of this reasoning, we conducted a preliminary analysis of the NGSS grading dataset. Our examination revealed that approximately 40% of the questions in the Science and Engineering Practices (SEP) dimension require the synthesis of information across at least two distinct conceptual nodes that are not co-located in the source text. For example, in Task 2 (Chemical Reactions in Soap Making), standard RAG frequently failed to grade responses correctly regarding the distinction between *descriptive* and *relational* explanations. The rubric required connecting "observation of property changes" to "evidence of new substance formation," and subsequently to "reasoning about chemical reaction mechanisms." Standard retrieval consistently fetched definitions of chemical reactions but missed the intermediate reasoning criteria that distinguish a descriptive listing of changes from a relational explanation connecting cause to effect. Without this structural retrieval, the LLM is forced to rely on its pre-trained internal parameters to infer these missing connections. This reintroduces the very risk of hallucination that RAG was intended to solve. Therefore, the central technical problem this work addresses is the "Context Fragmentation" problem: how to retrieve not just relevant isolated facts, but a connected subgraph of evidence that preserves the relational dependencies essential for validating complex student arguments.

4. METHODOLOGY

The proposed framework addresses the structural limitations of flat retrieval in automated grading by evaluating two distinct GraphRAG paradigms. Unlike standard RAG, which relies solely on vector similarity, these approaches explicitly model educational content as a structured network. This section details the distinct graph construction and retrieval strategies employed: the community-based summarization of Microsoft GraphRAG and the neurosymbolic associative memory of HippoRAG.

4.1 Community-Based Retrieval via Microsoft GraphRAG

To capture high-level thematic structures and hierarchical relationships within the course material, we employ the Microsoft GraphRAG framework. This approach moves beyond simple entity extraction by utilizing a modular graph construction technique. The system first segments the reference text and uses an LLM to identify entities and relationships, constructing a base knowledge graph. Crucially, it then applies the Leiden community detection algorithm to partition the graph into hierarchical clusters of related concepts. For each detected community, the system generates a natural language summary that synthesizes the key information contained within that cluster. During the grading phase, rather than retrieving raw text chunks, the system performs a "local search" that navigates these pre-computed community summaries. This ensures that when a student mentions a specific concept, the LLM receives a context window enriched with the broader thematic implications and neighbor-descriptions of that concept, providing a holistic view of the topic area (DCI) required for grading.

4.2 Neurosymbolic Retrieval with HippoRAG

Complementing the community-based approach, we employ HippoRAG to address the specific multi-hop reasoning requirements of the SEP dimension. HippoRAG utilizes a neurosymbolic approach inspired by the hippocampal indexing theory of human memory. Unlike the community-summary approach of Microsoft GraphRAG, HippoRAG maintains a direct link between graph nodes and the original source text chunks.The construction phase involves extracting po-

Table 1: Performance Comparison on NGSS Grading Tasks (Accuracy). Best results are highlighted in bold.

Average	0.389	0.309	0.334	0.409	0.322	0.321	**0.727**	**0.649**	**0.693**	0.720	0.535	0.658

tential entities from the corpus and building a knowledge graph where edges represent co-occurrence or semantic dependency. During retrieval, the system employs the Personalized PageRank (PPR) algorithm. When a student submits a response, the key terms in the answer act as "seed nodes" on the graph. The PPR algorithm propagates activation probability from these seeds to their neighbors, effectively traversing the graph to identify relevant concepts via multi-hop paths. This allows the system to retrieve a subgraph of evidence that includes not only the concepts explicitly mentioned by the student but also the logically connected upstream prerequisites and downstream consequences, thereby reconstructing the full reasoning chain $A \rightarrow B \rightarrow C$ necessary for accurate assessment.

4.3 Graph-Grounded Grading

The final phase involves synthesizing the retrieved context (whether from community reports or associative subgraphs) into a coherent prompt for the grading LLM. The model is instructed to verify the student's response against this structured narrative. By explicitly grounding the evaluation in the retrieved relationships (edges) rather than just isolated facts (nodes), the system converts the grading task from open-ended generation into a constrained graph verification problem.

5. EXPERIMENTS

To validate the efficacy of structural retrieval in automated grading, we conducted a comprehensive evaluation using the standard benchmark dataset reported in Chu et al. [1]. We compared our GraphRAG-driven approaches against the state-of-the-art flat RAG baseline across multiple scientific grading tasks.

5.1 Experimental Setup

Dataset. We utilized the short answer grading dataset established in [1], which is aligned with the Next Generation Science Standards (NGSS). The dataset consists of student responses across six distinct assessment tasks (task 1 through task 6). Each task is graded along three multidimensional learning distinct dimensions. DCI (disciplinary core ideas) is the evaluation of specific scientific content knowledge. SEP (science and engineering practices) is the assessment of the student's ability to engage in scientific reasoning and argumentation. CCC (crosscutting concepts) is the evaluation of connections between different scientific domains. This multidimensional scoring makes the dataset particularly challenging, as it requires the grading system to verify not just factual recall (DCI) but also logical process (SEP) and synthesis (CCC).

Baselines and Models. We benchmarked our proposed methods against the standard RAG implementation described by Chu et al. [1], which utilizes flat vector retrieval to fetch scoring rubrics. We implement HippoRAG as our primary neurosymbolic retrieval approach that utilizes personalized PageRank to capture multi-hop dependencies. We also include Microsoft GraphRAG (local), which is an entity-centric approach that retrieves context based on the ego-graphs of key terms found in the student response. We also performed an ablation study labeled *-Background*, examining the performance when the retrieval is constrained or focused specifically on the background knowledge graph components.

5.2 Main Results

Table 1 presents the comparative performance of the baseline RAG system versus our GraphRAG implementations (including Microsoft GraphRAG and HippoRAG). The results shown in Table 1 demonstrate that incorporating structural graph information significantly enhances grading accuracy across all dimensions.

Analysis of Structural Retrieval. Our HippoRAG implementation achieved the highest average performance across all three metrics, with a substantial improvement in the SEP dimension (0.649 vs. 0.322 for baseline RAG). This confirms our hypothesis that flat retrieval struggles with the reasoning chains required for SEP. By traversing the graph, HippoRAG successfully retrieves the intermediate logical steps that students implicitly rely on, allowing the LLM to verify their reasoning process rather than just keyword matching. Microsoft GraphRAG (local) also outperformed the baseline in DCI (0.720 vs. 0.409) and CCC (0.658 vs. 0.321), showing that entity-centric graph context is highly effective for factual verification, though it is slightly less effective than HippoRAG for capturing the complex procedural dependencies in SEP.

5.3 Ablation Study: Impact of Background Knowledge

We further investigated the impact of different retrieval configurations by isolating the background knowledge components. Table 2 details the performance of the *-Background* variants for both graph methods.

Table 2: Ablation Study on Background Knowledge Configuration

	HippoRAG - Background			MS GraphRAG - Background		
Task	**DCI**	**SEP**	**CCC**	**DCI**	**SEP**	**CCC**
Task 1	0.838	0.649	0.811	0.541	0.757	0.730
Task 2	0.652	0.935	0.978	0.587	0.761	0.891
Task 3	0.818	0.386	0.773	0.795	0.455	0.750
Task 4	0.391	0.413	0.609	0.478	0.478	0.652
Task 5	0.548	0.548	0.452	0.613	0.581	0.452
Task 6	0.891	0.370	0.326	0.870	0.435	0.348
Average	0.690	0.550	0.658	0.647	0.578	0.637

The ablation results highlight a distinct trade-off. While the full HippoRAG system (average SEP 0.649) outperforms the background-only variant (average SEP 0.550), the MS GraphRAG (local) - Background configuration achieved a higher SEP score (0.578) than its standard counterpart (0.535). This suggests that for certain entity-centric retrieval methods, focusing the context explicitly on background knowledge can enhance the model's ability to evaluate scientific practices, potentially by reducing noise from less relevant rubric details. However, for factual consistency (DCI), the full graph integration consistently yields the best results.

6. DISCUSSION

The experimental results provide strong evidence that structural retrieval methods substantially outperform flat vector-based approaches for automated short answer grading. In this section, we analyze representative case studies that illustrate the specific mechanisms by which GraphRAG improves grading accuracy, particularly in scenarios where baseline methods fail systematically.

6.1 Case Study 1: No-RAG Failure in SEP Assessment

The most striking performance gap between methods occurs in the Science and Engineering Practices (SEP) dimension of Task 2 (Chemical Reactions in Soap Making). The No-RAG baseline achieved only 4.3% accuracy on this dimension, essentially random performance, while HippoRAG achieved 84.8% accuracy, representing a 19× improvement.

The Assessment Challenge. The SEP dimension requires the grader to distinguish between *descriptive* explanations (merely listing observations) and *relational* explanations (connecting observations to underlying scientific principles). Consider the following student response:

> *"Your Claim: Yes a chemical reaction did occur. Evidence: Salubility in water. Before: #1=Yes #2=No. After: #1=No #2=yes. Reasoning: The salubility changed in water."*

This response should receive a score of 0 (descriptive) because while the student correctly identifies a property change, they fail to *explain why* this change indicates a chemical reaction occurred. The reasoning merely restates the observation without connecting it to the formation of new substances with different properties.

Why No-RAG Fails. Without access to grading rubrics, the LLM must rely on its pre-trained knowledge to evaluate whether an explanation is "relational." The model's general understanding of chemical reactions leads it to accept any mention of property changes as evidence of scientific reasoning. For instance, when evaluating:

> *"Evidence: All the numbers on density, mass, and melting point are all different which means it created something new with new properties. Reasoning: If it makes something new with new properties, that means it's a chemical reaction."*

The No-RAG system incorrectly classifies this as relational (score 1) because it *sounds* like scientific reasoning. However, according to the rubric, this is still descriptive: the student is applying a memorized rule ("new properties = chemical reaction") rather than constructing a relational explanation that connects specific property changes to the molecular rearrangement process.

Systematic Misalignment. Our analysis revealed that the No-RAG baseline consistently exhibited a pattern of *over-acceptance*: the model's prior knowledge about what constitutes "good" scientific explanation conflicts with the specific rubric criteria. The rubric requires students to go beyond identifying changes to explaining the *mechanism* connecting those changes: a nuance that generic pre-training cannot capture. This explains why SEP accuracy (4.3%) was dramatically lower than DCI accuracy (47.8%) for the same task: factual content (DCI) aligns better with the model's training distribution, while procedural reasoning (SEP) requires task-specific criteria.

6.2 Case Study 2: GraphRAG Success through Structural Context

In contrast to the No-RAG failure, HippoRAG achieved 84.8% accuracy on Task 2 SEP by retrieving structured grading criteria that explicitly define the distinction between descriptive and relational explanations.

Retrieved Context Analysis. When processing the same student responses, HippoRAG retrieved interconnected passages that form a coherent grading framework:

1. **Assessment Criteria Node**: "A Level 0 response (coded as 0) shows incomplete understanding... The student may not correctly identify the reaction as chemical, confuse physical and chemical changes, or not recognize that new substances are formed with different properties."
2. **Level 0 Example Node**: "Yes a chemical reaction did occur. Salubility in water Before: #1=Yes #2=No After: #1=No #2=yes. The salubility changed in water." This response notes a property change but doesn't explain why this indicates a chemical reaction or mention new substances.
3. **Key Concepts Bridge Node**: "When evaluating student understanding of chemical reactions, look for: (1)

Recognition that new substances are formed, (2) Identification of evidence for chemical change, (3) Understanding that the reaction cannot be easily reversed, (4) Recognition that atoms are rearranged to form new molecules."

Multi-Hop Retrieval in Action. The critical advantage of HippoRAG lies in its ability to traverse the knowledge graph to retrieve the "Key Concepts Bridge Node" even when the student's response does not explicitly contain the terminology in that node. The Personalized PageRank algorithm propagates activation from the seed concepts ("chemical reaction," "property change") through the graph edges to reach the bridging criteria. This multi-hop traversal is precisely what flat retrieval cannot achieve: standard vector similarity would not retrieve the "Key Concepts" passage because it shares limited lexical overlap with the student's response.

Grounding the Decision. With this structured context, the LLM can perform a constrained verification rather than open-ended generation. The model observes that the student's response ("The salubility changed in water") matches the Level 0 example almost verbatim, and that the response lacks the key indicators defined in the bridge node (no mention of new substances, molecular rearrangement, or irreversibility). The grading decision becomes a graph verification task: does the student's reasoning path through the conceptual space match a valid path defined in the rubric graph?

6.3 Case Study 3: Distinguishing Relational from Descriptive Explanations

To further illustrate the nuanced distinction that GraphRAG enables, consider two student responses that differ subtly but critically:

Response A (Correctly graded as 0 - Descriptive):

> *"Claim: A chemical reaction did happen.*
> *Evidence: The lye reacted with the oil.*
> *Reasoning: Because the lye and coconut oil heated together to make a germ-killing solid."*

Response B (Correctly graded as 1 - Relational):

> *"Claim: When Mixing Coconut Oil With lye and heating them up a chemical reaction does occur.*
> *Evidence: The Melting Point of Coconut Oil is 27° C, The melting Point of lye is 318° C. The Melting point of the soap he created was 48° C. The Melting Point of Glycerol is 17° C.*
> *Reasoning: The melting point of Coconut Oil and lye before they were combined was very different than after they were mixed together with heat."*

Both responses identify property changes and conclude that a chemical reaction occurred. However, Response B provides *specific quantitative evidence* and *explicitly connects* the before/after property differences to support the claim. Response A merely describes what happened ("heated together to make a solid") without explaining *why* this transformation constitutes evidence of a chemical reaction.

GraphRAG's Discrimination Mechanism. HippoRAG's retrieved context includes the Level 1 criteria: "The student provides specific evidence about formation of new substances with different properties." The graph traversal also retrieves example Level 1 responses that demonstrate the expected level of specificity. By providing this contrastive context, both what constitutes Level 0 and Level 1, the LLM can accurately position Response A as descriptive (lacks specific property values) and Response B as relational (explicitly compares specific melting points before and after). The No-RAG and standard RAG baselines lack this contrastive grounding. Without explicit examples of both categories, these systems tend to accept any response that mentions property changes as "relational," leading to systematic overscoring.

6.4 Implications for Educational Assessment

These case studies reveal several important implications for the design of automated grading systems:

Task-Specific Criteria are Essential. The dramatic failure of No-RAG (4.3% SEP accuracy) demonstrates that LLMs cannot reliably apply task-specific grading standards from general knowledge alone. Even sophisticated models with extensive pre-training require explicit rubric context to distinguish nuanced categories like descriptive vs. relational explanations.

Structural Retrieval Enables Multi-Hop Reasoning. The success of HippoRAG on SEP tasks (84.8% vs. 4.3% for No-RAG) is directly attributable to its ability to retrieve conceptually related but lexically distinct passages. The "bridge nodes" that define grading criteria are often not semantically similar to student responses, making them invisible to flat vector retrieval but accessible through graph traversal.

Contrastive Examples Help Discrimination. GraphRAG's retrieval of both positive and negative examples (Level 0 and Level 1 responses) provides the LLM with decision boundaries rather than isolated definitions. This contrastive grounding is particularly important for grading tasks that require fine-grained categorical distinctions.

7. CONCLUSION

This work demonstrates that graph retrieval-augmented generation (GraphRAG) significantly outperforms standard flat vector retrieval for automated short answer grading. Our evaluation of Microsoft GraphRAG and HippoRAG on an NGSS-aligned dataset reveals substantial improvements across all grading dimensions, with HippoRAG achieving the most significant improvement in SEP accuracy. This dramatic gap occurs because SEP assessment requires distinguishing nuanced categorical distinctions that demand explicit rubric criteria, which is the context that graph-based multi-hop retrieval can provide but flat vector search cannot. Our findings suggest that for higher-order assessment tasks evaluating scientific reasoning, structural retrieval is essential for achieving alignment with human expert judgment. Future work will explore domain-specific educational knowledge graphs and personalized retrieval based on anticipated student misconceptions.

ABSTRACT

360-degree classroom video captures entire learning spaces using omnidirectional recording, preserving group-level context and reducing blind spots associated with fixed-view cameras. This affords advantages for analyzing non-verbal behaviors central to understanding collaborative interaction. However, manual annotation of such video remains time-consuming and difficult to scale. Multimodal large language models (MLLMs) offer a promising alternative: unlike traditional computer vision models that often struggle with the curvilinear distortion and viewpoint variation, MLLMs can leverage global context and semantic cues to interpret complex scenes. Yet applying MLLMs to 360-degree video requires decisions about how panoramic scenes are represented and how temporal information is sampled, factors known to influence model performance but rarely examined in educational contexts. This exploratory case study investigates how video extracted views (front-facing vs. top-down view) and temporal sampling density (1–4 frames per second) influence MLLM-based detection of non-verbal behaviors. We applied Molmo2-8B to 360-degree classroom recordings of small groups collaborative learning and evaluated detection performance across gaze, gesture, posture and tool usage behaviors. Results reveal that object-related behaviors (e.g., gaze at laptop, tool usage) were detected more reliably than social behaviors requiring inference about interpersonal coordination (e.g., gaze at other students). Projected view shaped detectability: top-down views supported more reliable detection of gaze- and tool-related behaviors by preserving spatial context. However, higher sampling rates did not consistently improve detection, suggesting that more frames are not always better. Together, these findings can inform 360-degree video preprocessing decisions when applying MLLMs to video analysis.

Multimodal large language models, 360-degree video, Collaborative learning, Non-verbal behavior detection

1. INTRODUCTION

Understanding collaborative learning requires attention not only to what learners say or produce, but also to how they coordinate through non-verbal behavior [14]. Gaze, gesture, posture, and shared tool use play important roles in establishing joint attention, signaling understanding, and regulating turn-taking during group work [3, 20, 16]. Research in learning sciences has long recognized these behaviors as indicators of productive collaboration—moments when learners build shared understanding, negotiate meaning, or struggle to coordinate [40, 43]. Capturing these dynamics is essential for understanding how collaboration unfolds and for designing interventions that support effective group learning [15, 50]. Yet, non-verbal behaviors remain difficult to capture through interaction logs or textual data alone, making classroom video a central data source for examining collaborative learning processes [13, 25].

To capture these non-verbal dynamics in situ, researchers have relied on classroom video recordings. Traditional front-facing cameras require researchers to make early decisions about camera placement and viewing angle, which can re-

sult in occlusion or loss of information when learners move outside the camera's limited field of view [10]. These constraints are especially problematic in collaborative learning settings. Recent advances in video capture technology have sought to address these limitations. In particular, wide angle and 360-degree cameras enable capture of entire learning spaces, reducing blind spots and preserving group-level context across multiple learners [2, 39, 47]. Although 360-degree recording addresses some of these limitations, it introduces new challenges. Researchers need to reconstruct and reprocess video from distorted equirectangular projection, and manage the increased complexity of processing panoramic footage. These technical demands compound the already substantial cost of manual video annotation, which has long constrained the scale of research on collaborative learning, often limiting analysis to small samples or brief episodes [58]. Prior work has explored computer vision techniques to automate classroom video analysis, including methods for detecting gaze direction, gesture, and body posture [21, 62, 57]. These approaches have shown promise but typically rely on task-specific pipelines and can be sensitive to viewpoint variation and visual distortion in 360-degree video [6, 19].

Multimodal large language models (MLLMs), a class of vision-language models capable of processing video input, have recently emerged as a promising alternative [23, 59]. By integrating visual perception with natural language generation, MLLMs offer a unified interface for describing a wide range of behaviors, potentially lowering the technical barrier to video-based research [51]. However, existing research provides limited guidance for educational applications. Empirical evaluations of MLLMs primarily rely on standardized benchmarks developed outside educational domains [53, 56], offering limited insight into how MLLMs perform on the context-dependent behaviors that characterize learner interactions. Meanwhile, work on MLLMs in education has remained largely conceptual rather than empirically examining model performance in authentic learning settings [5]. There is also limited understanding of how analytic conditions shape MLLM performance, as model outputs are impacted not only by architecture but also by representation choices and dataset characteristics [11]. These factors are particularly consequential for 360-degree video, where researchers must make explicit decisions about how panoramic footage is projected, framed, and sampled before it can be processed by a model. Yet how such preprocessing decisions affect MLLM performance remains an open question.

This study addresses this question by empirically examining two analytic design choices: video extracted views (how the panoramic scene is projected and framed) and temporal sampling (how many frames are extracted per clip). Focusing on concrete, observable non-verbal behaviors relevant to collaborative learning, we investigate how these choices affect behavior detection performance in 360-degree classroom video. Rather than proposing a fully automated solution, this exploratory case study adopts a diagnostic perspective aimed at identifying the conditions under which MLLM-based analysis of 360-degree video is effective or limited. The following research questions guide this study:

RQ1: How does temporal sampling density affect MLLM-based detection of non-verbal behaviors in 360-degree classroom video?

RQ2: How does video extracted view affect MLLM-based detection of non-verbal behaviors?

2. LITERATURE REVIEW

2.1 360-Degree Video in Educational Research

Advances in 360-degree camera technology present new opportunities for using 360 cameras for teaching and learning [41, 17, 35]. 360-degree cameras capture entire learning environments from a single vantage point, recording omnidirectional views that can be navigated from multiple perspectives [17, 35]. Unlike traditional or multi-camera setups that require coordination among multiple devices, 360-degree cameras present explorable spherical scenes that allow researchers and educators to revisit and navigate the learning space, supporting a deeper examination of instructional practices, learners' engagement, and other social dynamics that occur in the classroom [39, 2]. 360-degree cameras are increasingly used in education for purposes ranging from exam proctoring [1] to immersive training environments, including surgical simulation [24], public speaking practice [44], and observation of teaching practices [48]. However, this flexibility introduces a distinct challenge during video processing. With traditional front-facing cameras, the viewing angle is determined at the time of recording. In contrast, 360-degree video defers this decision to the processing stage, requiring researchers to actively choose how to project and frame the spherical scene for analysis. These decisions are often guided by analytic priorities. Front-facing projections maximize visibility of facial expressions and gaze direction, whereas top-down views better capture spatial arrangements and interactions among group members at a shared workspace [33, 42]. These early choices about viewing angles influence ground-truth annotation and the inputs provided to automated models, making representation selection consequential for human and computational analysis.

These representational decisions compound a broader set of challenges limiting the use of 360-degree video in learning analytics. Processing such footage demands substantial computational resources [32], and standard computer vision models trained on conventional camera footage struggle with 360-degree recordings. Facial, body, and object recognition models often fail due to equirectangular distortion and occlusion common in omnidirectional footage [38]. These challenges point to the need for a systematic evaluation of both video processing methods and computational approaches for collaborative learning analysis.

2.2 Detecting Non-Verbal Behaviors

Early efforts to automate behavior detection have relied on computer vision models trained for specific tasks such as gaze estimation [62], pose detection [55], and gesture recognition [22]. While these approaches have shown promise in controlled settings, they require assembling separate pipelines for each behavior type. For instance, detecting gaze direction may require sequential application of face detection, landmark localization, head pose estimation, and gaze regression, each trained independently and requiring calibration [62]. This presents a substantial engineering burden. A further challenge is that most models are trained on images

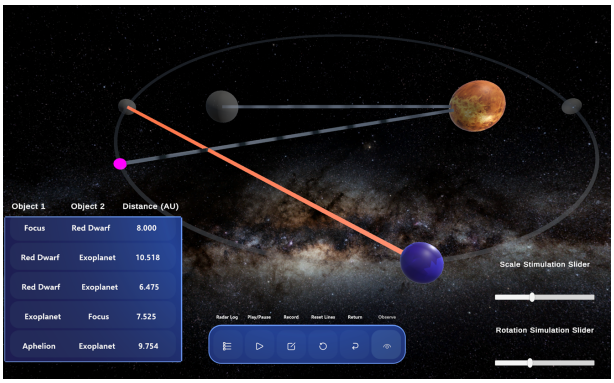

Figure 1: A web-based immersive science learning simulation.

from standard cameras, assuming consistent scale, frontal viewpoints, and minimal occlusion [57]. As a result, they often struggle to generalize to 360-degree video, where equirectangular projection introduces curvilinear distortion that warps object shapes and spatial relationships [45, 6, 54]. These limitations highlight the need for approaches that can handle the unique visual characteristics of 360-degree footage.

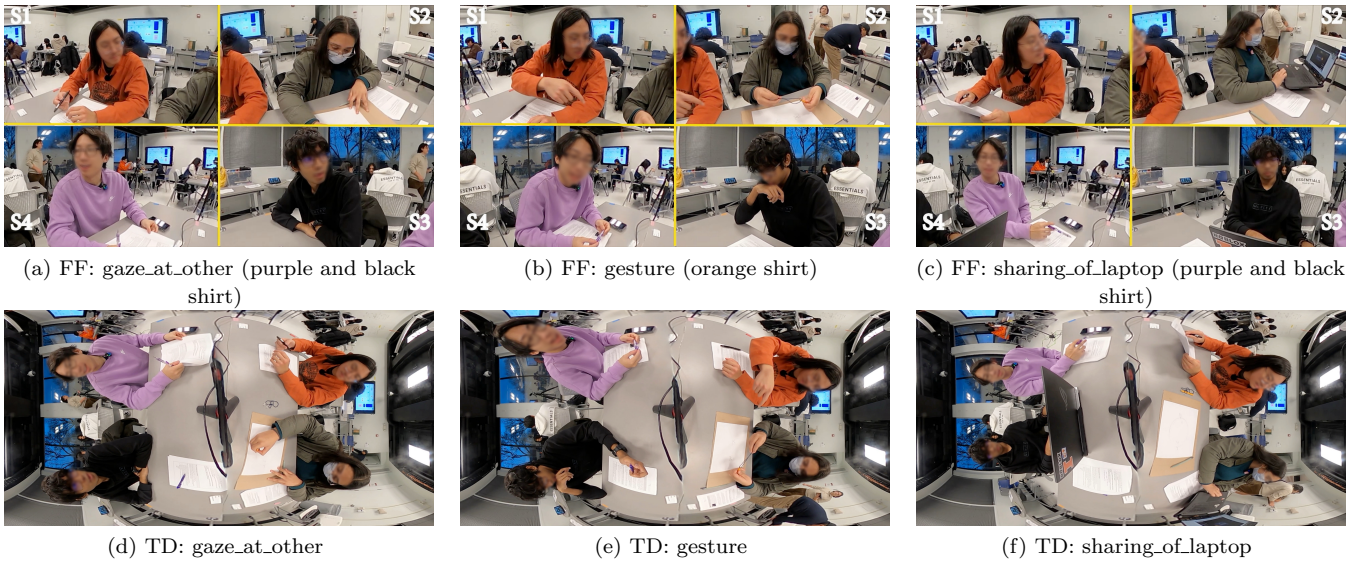
MLLMs offer several potential advantages. First, a single model can describe multiple behavior types without separate pipelines, substantially reducing engineering effort[51]. Second, MLLMs can leverage global context and semantic cues to produce partially grounded interpretations; this context-aware reasoning may support more robust detection of behaviors [60, 56]. Finally, MLLMs produce natural-language outputs that are directly interpretable. But MLLM performance is impacted by how video is represented for input and how temporal information is sampled [26]. Without empirical evidence on how these analytic choices influence behavior detection, it remains unclear when MLLMs can reliably support non-verbal behavior analysis. By identifying which behaviors are robust to variation in representation and temporal sampling, and which are highly sensitive to these choices, such work helps researchers calibrate their validation efforts, anticipating when MLLM outputs are likely to be more or less reliable, and where closer inspection or alternative approaches may be required.

3. METHODS

3.1 Context and Participants

Data were collected during group activities in an introductory curriculum and instruction course at a Midwestern University. Students engaged with a simulation designed to teach planetary motion and Kepler's laws (Figure 1), completing a structured group activity involving exploration, data collection, and reflection. A total of 24 out of the 39 students across two classroom sessions consented to participate in the research and worked in groups of two to four. This study focused on one four-student group as a case for examining analytic design choice. The group was selected because the video had high visual quality, all group members remained relatively visible during the focal period, and students worked around a shared workspace with two laptops and worksheets. These features made it possible to compare how the same collaborative activity was represented under different view and sampling conditions. Accordingly, the study should be interpreted as a case-based analysis of preprocessing and detection conditions. Ethical approval was obtained from the institutional review board. All participants provided informed consent for research use of the recordings. Video data were stored and analyzed under approved research procedures.

3.2 Video Data



The selected group's video lasted approximately 40 minutes. Based on preliminary review, we focused our analysis on the first 20 minutes, after which cross-group interactions became infrequent. Raw `.360` files were converted to `.mp4` (ProRes) using GoPro Player with H.264 encoding and equirectangular projection. Adobe Premiere Pro v24.1 with a GoPro 360 plugin was then used to extract two viewing conditions (Figure 2). The front-face (FF) view was designed to isolate and maximize the exposure of individual faces to the camera lens, while the top-down (TD) view was designed to isolate and maximize the exposure of the group's physical interactivity around the table. These two views should not be understood as neutral representations containing identical visual information. Rather, they foreground different aspects of the same 360-degree recording. The FF view provides more direct access to faces and upper-body orientation, whereas the TD view more clearly exposes the table layout, shared artifacts, and relative positioning among students. The comparison therefore examines how view-specific information availability shapes MLLM-based detection. Final videos were rendered at 24 fps and 1080p resolution in `.mp4` format.

3.3 Behavior Annotation

Behavior selection was guided by prior work in collaborative learning and non-verbal interaction analysis [14]. The annotation protocol focused on observable, externally visible behaviors, excluding inferences about internal cognitive or affective states. The video was segmented into non-overlapping 10-second clips before annotation. For each clip, trained annotators assigned binary labels indicating whether each behavior in Table 1 was visibly present at any point during the clip. Two trained annotators independently coded the video corpus using the behavior taxonomy summarized in Table 1. Inter-rater agreement was calculated separately for each behavior category using Cohen's kappa over the 10-second clip-level binary labels. Disagreements were resolved through discussion before producing the final reference labels used for model evaluation. Inter-rater reliability exceeded Cohen's $\kappa > 0.75$ for all behavior categories.

3.4 MLLM-Based Behavior Detection

Model and Configuration. We employed Molmo2-8B at full precision (BF16) without quantization. This is an open-weight vision-language model designed for multimodal understanding [12]. Molmo2 integrates a Vision Transformer encoder with a decoder-only language model, using multi-headed attention pooling and an overlapping multi-crop strategy to capture fine-grained visual details with surrounding context. Rather than treating video as an unordered collection of frames, the model associates visual tokens with temporal context, supporting description of actions and events unfolding over short video segments. Molmo2 emphasizes

(a) FF: gaze_at_other (purple and black shirt)

(b) FF: gesture (orange shirt)

(c) FF: sharing_of_laptop (purple and black shirt)

(d) TD: gaze_at_other

(e) TD: gesture

(f) TD: sharing_of_laptop

Figure 2: Example video frames showing non-verbal behaviors in front-face (FF) and top-down (TD) views. Faces and identifying features are obscured for privacy.

Table 1: Behavior taxonomy and frequencies (N=121).

Behavior	Sub-behavior	Definition	Frequency
Gaze	Gaze_at_worksheet	Student looks at the worksheet.	110
	Gaze_at_laptop	Student looks at the laptop.	84
	Gaze_at_other_students	Student looks at another student's face or body.	20
	Gaze_away	Student looks away from their own group or the task.	13
Gesture	Gesture	Student shows gesture like pointing or other hand movement without interacting with objects.	26
Posture	Lean_forward	Student's upper body shifts towards the table.	104
	Headnod	Student moves their head up and down in a nodding motion.	21
	Lean_adjacent	Student shifts to be closer to the adjacent student.	64
Tool Usage	Usage_of_worksheet	Student is actively using the worksheet.	99
	Usage_of_laptop	Student is actively using the laptop.	74
	Sharing_of_laptop	Students share a laptop (i.e., a laptop is present in front of two students).	84

visual grounding through its ability to output 2D points corresponding to pixels supporting its answers. Molmo2-8B was selected for three reasons. First, it is open-weight with a fixed model checkpoint, ensuring exact reproducibility. Second, it achieves benchmark performance comparable to proprietary models such as GPT-4o [12]. Third, its 8B-parameter size allows inference on widely available hardware.The pre-trained model was used without fine-tuning as this work aims to assess baseline model behavior. Temperature was set to zero to ensure deterministic outputs. Inference was conducted on a single NVIDIA H200 GPU.

Video Segmentation. We adopted video-level rather than frame-level behavior detection to support identification of temporal behaviors such as posture changes. To implement this, videos were segmented into fixed-length 10-second clips, a duration that balances temporal context against computational constraints and aligns with the broader multimodal learning analytics project in which this study is situated. Fixed-length segmentation reflects realistic deployment scenarios and avoids reliance on event-based heuristics.

Prompt Design. Each prompt consisted of a system message and a task-specific text prompt. The prompt design draws on prior empirical work showing that explicit role assignment and task framing improve MLLM output quality for educational video analysis [49, 63]. The prompt instructed the model to: *"Act as an educational researcher specializing in qualitative and ethnographic video analysis. Your task is to observe the video clip and determine whether the following [BEHAVIOR-CATEGORY]-related behaviors are visually observable. Base your judgment only on visible, externally observable cues, and do not infer attention, intention, engagement, or internal states. If a behavior is ambiguous, partially occluded, or too subtle to identify with confidence, mark it as not detected (0)."* This was followed by behavior definitions for each category (see Table 1). Prompts required machine-parsable output and were held constant across all

experimental conditions.

Experimental Design. We employed a 2 × 4 factorial design, varying video representation (front-facing vs. top-down) and temporal sampling rate (1–4 FPS) while holding model configuration and prompts constant. MLLM outputs were then evaluated against human annotations. Due to space constraints, the main paper reports accuracy and F1 score while full results including precision and recall are provided in the supplementary materials at `https://anonymous.4open.science/r/EDM2026-4CC0/`. Because the dataset is imbalanced and several behavior categories were relatively infrequent (e.g., gaze away and headnod; Table 1), accuracy and F1 scores should be interpreted with caution. In particular, high accuracy may partly reflect base rates for low-frequency behaviors, while low or unstable F1 scores may reflect data sparsity as well as model difficulty. For this reason, full per-behavior precision and recall results are provided in the supplementary materials.

4. RESULTS

4.1 Effects of Temporal Sampling (RQ1)

To examine how temporal sampling density influenced MLLM-based detection within this specific setup, we compared model performance across four frame rates (1–4 FPS) under both views (see Table 2 and 3). Within the present 10-second clip setup and 1- 4 FPS range, increasing sampling density did **not** yield consistent improvements in detection performance.

Sustained behaviors (i.e., actions that persist over multiple seconds) demonstrated high and stable detection across all FPS conditions. `gaze_at_worksheet` maintained strong performance in both views (FF: F1 0.95–0.96; TD: F1 0.93–0.96), as did `lean_forward` in the TD view (F1 0.92–0.93). Tool usage behaviors all maintained high performance regardless of FPS: `usage_of_worksheet` (TD: F1 0.88–0.89), `usage_of_laptop` (TD: F1 0.89–0.90), and `sharing_of_laptop` (TD: F1 0.89–0.91). These results indicate that for sustained behaviors, lower sampling rates (1–2 FPS) are sufficient. In contrast, several behaviors proved persistently difficult to detect regardless of sampling density. `lean_adjacent` showed consistently low F1 scores in both views (FF: 0.00–0.17; TD: 0.00–0.06), with accuracy close to the base rate (53%). `headnod` exhibited similarly poor detection (FF: F1 0.00–0.09; TD: F1 0.00–0.36). Social gaze behaviors (i.e., `gaze_at_other` and `gaze_away`) also remained challenging across all sampling rates. For these behaviors, FPS variation did not meaningfully improve performance in this setup, suggesting that sampling density alone may not address detection challenges that arise from relational inference, occlusion, or low behavioral frequency.

Only a small number of behaviors showed sensitivity to sampling density. `gesture` in the FF view improved modestly (F1 0.12 at 1 FPS to 0.31 at 4 FPS), suggesting that transient hand movements may benefit from denser temporal coverage. However, this pattern did not hold in the TD view, where `gesture` peaked at 2 FPS (F1 0.39) and declined at higher rates (F1 0.21–0.23). This divergence might point to view-dependent effects on temporal sampling. Other behaviors similarly showed degraded performance at higher rates: `lean_forward` in the FF view declined from accuracy 0.88 and F1 0.93–0.94 at 1–2 FPS to accuracy 0.69–0.70 and F1 0.80–0.81 at 3–4 FPS. `gaze_at_laptop` (FF) decreased from F1 0.30 to 0.19 across the FPS range, and `sharing_of_laptop` (FF) peaked at 2 FPS (F1 0.86) before declining (F1: 0.71–0.73). Together, these findings suggest that uniform increases in temporal sampling do not reliably improve detection performance within this case and sampling range, and that the effects of sampling rate are both behavior- and representation-dependent.

Table 2: Accuracy across FPS for each behavior by view.

Feature	View	FPS1	FPS2	FPS3	FPS4
gaze_at_worksheet	FF	0.92	0.92	0.90	0.90
	TD	0.88	0.92	0.89	0.91
gaze_at_laptop	FF	0.43	0.42	0.37	0.38
	TD	0.91	0.91	0.81	0.90
gaze_at_other	FF	0.84	0.84	0.84	0.84
	TD	0.82	0.41	0.78	0.76
gaze_away	FF	0.85	0.64	0.89	0.89
	TD	0.88	0.73	0.89	0.87
gesture	FF	0.74	0.79	0.79	0.77
	TD	0.55	0.71	0.74	0.66
lean_forward	FF	0.88	0.88	0.70	0.69
	TD	0.86	0.86	0.88	0.88
headnod	FF	0.82	0.83	0.83	0.83
	TD	0.82	0.76	0.82	0.83

	TD	0.79	0.79	0.79	0.81
usage_of_laptop	FF	0.64	0.69	0.64	0.66
	TD	0.88	0.88	0.86	0.88
sharing_of_laptop	FF	0.72	0.82	0.69	0.70
	TD	0.88	0.86	0.85	0.86

4.2 Effects of Representation View (RQ2)

To examine how video representation influences MLLM-based detection, we compared performance between FF and TD views (see Tables 2 and 3). Performance differed across views, with the TD view generally providing visual information that supported more reliable detection, particularly for behaviors involving shared artifacts and spatial context.

The TD view showed stronger performance for object-related behaviors. `gaze_at_laptop` showed markedly stronger performance in the TD view (F1 0.84–0.93) compared to the FF view (F1 0.17–0.30). Similar patterns emerged for `usage_of_laptop` (TD: F1 0.89–0.90 vs. FF: F1 0.59–0.67) and `sharing_of_laptop` (TD: F1 0.89–0.91 vs. FF: F1 0.71–0.86). These behaviors require information about spatial relationships between learners and artifacts, which was more visible in the global scene layout preserved in top-down projections.

For highly salient sustained behaviors, both views achieved comparable performance. `gaze_at_worksheet` was detected reliably across representations (FF F1 0.95–0.96; TD F1 0.93–0.96), as was `usage_of_worksheet` (FF F1 0.89–0.91; TD F1 0.88–0.89). `lean_forward` performed similarly at

Table 3: F1 score across FPS for each behavior by view.

Feature	View	FPS1	FPS2	FPS3	FPS4
gaze_at_worksheet	FF	0.96	0.96	0.95	0.95
	TD	0.93	0.96	0.94	0.95
gaze_at_laptop	FF	0.30	0.29	0.17	0.19
	TD	0.93	0.93	0.84	0.92
gaze_at_other	FF	0.10	0.23	–	–
	TD	0.39	0.30	0.40	0.17
gaze_away	FF	0.25	0.24	–	–
	TD	0.30	0.33	0.44	0.11
gesture	FF	0.12	0.25	0.29	0.31
	TD	0.31	0.39	0.21	0.23
lean_forward	FF	0.93	0.94	0.81	0.80
	TD	0.92	0.92	0.93	0.93
headnod	FF	–	0.09	–	–
	TD	–	0.36	–	–
lean_adjacent	FF	0.06	0.17	–	–
	TD	0.03	0.06	–	–
usage_of_worksheet	FF	0.99	0.91	0.90	0.89
	TD	0.88	0.88	0.88	0.89
usage_of_laptop	FF	0.61	0.67	0.59	0.62
	TD	0.90	0.90	0.89	0.90
sharing_of_laptop	FF	0.75	0.86	0.71	0.73
	TD	0.91	0.89	0.89	0.89

lower sampling rates (FF F1 0.93–0.94; TD F1 0.92–0.93), although the FF view showed degradation at higher FPS. These behaviors appear sufficiently visually distinctive that representation choice has limited impact on detection. In contrast, socially oriented behaviors proved difficult to detect under both representations. `gaze_at_other` yielded low and unstable F1 scores in both views (TD: 0.17–0.40; FF: 0.10–0.23), as did `gaze_away` (TD: 0.11–0.44; FF: 0.24–0.25). `lean_adjacent` and `headnod` remained near zero across all conditions in both views. These behaviors require relational inference about interpersonal coordination, a challenge that neither representation resolved.

5. DISCUSSION

5.1 Temporal Sampling: When Less May Be More

Results for RQ1 show that higher frame sampling rates did not consistently improve detection performance,within the present 10-second clip setup and 1- 4 FPS range. This finding should not be interpreted as a general claim that fewer frames are always preferable. Rather, it suggests that the value of additional frames depends on the temporal characteristics of the target behavior, the length of the clip, and the model's visual token and context constraints. Within 10-second segments, denser sampling may add redundant frames when behaviors are sustained across multiple seconds. This pattern is consistent with recent findings showing that uniform increases in FPS can plateau or even degrade performance when adjacent frames are highly similar [34, 36]. Many collaborative learning behaviors, such as gazing at a worksheet or maintaining a forward-leaning posture, unfold over several seconds. At higher sampling rates (e.g., 3–4 FPS), the model processes many near-identical frames. This redundancy may dilute the model's effective attention under fixed token budgets and increase sensitivity to minor visual variations [34]. In contrast, transient behaviors may benefit from higher sampling rates to capture momentary behavioral cues. These findings therefore support behavior-aware sampling rather than uniformly increasing FPS.increasing FPS.

5.2 Affordances for Behavior Detection

Results for RQ2 indicate that video representation impacts which non-verbal behaviors can be reliably detected by video-based MLLMs. A key methodological caveat is that FF and TD views do not contain identical visual information. They are different input conditions that organize visibility in different ways. The TD view more clearly exposes the table layout, shared artifacts, and relative body positions, whereas the FF view provides more direct access to faces and upper-body cues but may obscure the broader workspace. Therefore, the observed differences should be interpreted as view-specific differences in information availability, rather than evidence that the model is inherently better suited to one projection type.

TD views supported more reliable detection of several gaze- and tool-related behaviors, particularly those involving shared artifacts or spatial coordination among learners. This advantage aligns with insights from group activity recognition, which emphasizes that many collaborative behaviors depend on the spatial configuration of multiple participants rather than isolated individual cues [7, 52].

Detecting such behaviors requires knowing whether multiple learners are oriented toward the same object, how close they are to one another, and how their bodies are arranged in space. TD views appear to support these inferences by preserving the global layout of the learning environment, including the relative positions of learners, shared artifacts, and workspaces. By reducing occlusion, normalizing scale differences across learners, and exposing shared reference frames, TD representations foreground scene-level context and inter-person relations that are difficult to reconstruct from frontal viewpoints alone. Similar advantages of global or overhead perspectives have been reported in prior work on collaborative activity recognition, where preserving spatial context improves robustness under occlusion and viewpoint variation [7, 28, 52].

FF views, while less effective overall in our evaluation, have demonstrated strengths in prior work using traditional computer vision approaches. They provide higher resolution of facial features, hand positions, and upper-body movements [4]. Prior research on classroom analytics suggests that such perspectives are well suited for detecting individual-level nonverbal cues, including head orientation, eye gaze, and affect detection [29, 38]. In the present study, however, these advantages did not translate to improved MLLM-based detection as FF views yielded weaker and less stable performance than TD views across most behavior categories. One possible explanation is that MLLMs and traditional computer vision pipelines leverage visual information differently: whereas specialized computer vision models can ex-

tract fine-grained facial features from frontal views, MLLMs may rely more heavily on global scene context and semantic cues that are better preserved in TD representations. Additionally, in multi-learner settings, FF views often obscure the broader context needed to infer group-level coordination [31]. Taken together, these findings suggest that no single representation is universally optimal. Representation choice should be guided by analytic goals and methods. Future work should examine whether combining FF and TD information through early or late fusion yields more robust detection [52].

5.3 Object-Related vs. Social Behaviors

One key finding of this study is that object-related behaviors—those involving direct interaction with physical materials such as worksheets and laptops—were detected more reliably than social behaviors requiring inference about interpersonal attention or coordination. For example, higher F1 scores and accuracy were observed for `gaze_at_laptop` and `gaze_at_worksheet` compared to `gaze_at_other`.

Object-related behaviors primarily require perceptual grounding: recognizing the presence of an artifact and identifying that a learner's gaze or action is directed toward it. Such judgments rely largely on visual pattern matching and benefit from model pretraining on large-scale object recognition data [37]. In contrast, social behaviors require relational inference across participants. Rather than identifying a single target, the model must integrate cues about spatial arrangement, body orientation, and temporal coordination [8, 62]. In 360-degree classroom video, this relational inference is further complicated by wide fields of view and spatial distortion.

These demands remain challenging for current MLLMs, which have been shown to exhibit systematic limitations in interpreting subtle relational aspects of human interaction [30]. These findings have practical implications for the design of MLLM-based analytics pipelines. Object-related behaviors may be more amenable to scalable automated analysis with comparably less human oversight, while social behaviors may require specialized models for detecting interpersonal coordination, such as eye contact and shared attention [18, 46, 28].

5.4 Limitations and Future Work

This study has several limitations. First, This study should be interpreted as a case-based analysis rather than a general evaluation across classroom contexts. The analysis was based on one four-student group, one task, one classroom configuration, and the first 20 minutes of a single 360-degree recording. The selected group was not randomly sampled; it was chosen because the video quality was high and the shared workspace made FF/TD comparisons analytically tractable. As a result, group-level factors such as seating arrangement, communication style, division of labor, technology-use patterns, and visibility of shared artifacts may have influenced the observed differences between FF and TD views. Second, evaluation was conducted using a single MLLM (Molmo2-8B), limiting generalizability to other vision–language models. Differences in architecture, pretraining data, and visual encoding strategies may substantially influence behavior detection performance [9]. Future work should test whether the observed patterns hold across other open-source and proprietary models. Third, the study focused on a specific taxonomy of non-verbal behaviors relevant to collaborative learning. While theoretically grounded, this taxonomy does not exhaustively capture all educationally meaningful behaviors. Third, the study examined only zero-shot inference without fine-tuning or prompt optimization. Although this reflects realistic use cases for many researchers, performance likely underestimates what could be achieved with task-specific adaptation. Techniques such as many-shot in-context learning or chain-of-thought prompting may improve detection accuracy [27, 61].

Beyond these limitations, future research could explore adaptive sampling strategies tailored to specific behavior dynamics, multi-view fusion approaches that leverage complementary perspectives, and fine-tuning methods that adapt pretrained MLLMs to educational contexts. Integrating MLLM-based video analysis with additional data streams—such as audio transcripts, interaction logs, or physiological sensors—also offers promising directions for advancing multimodal learning analytics.

ABSTRACT

The rapid adoption of large language models (LLMs) in education raises profound challenges for assessment design. To adapt assessments to the presence of LLM-based tools, it is crucial to characterize the strengths and weaknesses of LLMs in a generalizable, valid and reliable manner. However, current LLM evaluations often rely on descriptive statistics derived from benchmarks, and little research applies theory-grounded measurement methods to characterize LLM capabilities relative to human learners in ways that directly support assessment design. Here, by combining educational data mining and psychometric theory, we introduce a statistically principled approach for identifying items on which humans and LLMs show systematic response differences, pinpointing where assessments may be most vulnerable to AI misuse, and which task dimensions make problems particularly easy or difficult for generative AI. The method is based on Differential Item Functioning (DIF) analysis – traditionally used to detect bias across demographic groups – together with negative control analysis and item-total correlation discrimination analysis. It is evaluated on responses from human learners and six leading chatbots (ChatGPT-4o & 5.2, Gemini 1.5 & 3 Pro, Claude 3.5 & 4.5 Sonnet) to two instruments: a high school chemistry diagnostic test and a university entrance exam. Subject-matter experts then analyzed DIF-flagged items to characterize task dimensions associated with chatbot over- or under-performance. Results show that DIF-informed analytics may provide a theory-grounded framework for understanding where LLM and human capabilities diverge, and highlight their value for improving the design of valid, reliable, and fair assessment in the AI era.

1. INTRODUCTION

The rapid adoption of generative AI (GenAI[1]) tools in education has created both opportunities and risks. While these systems, particularly chatbots such as ChatGPT, can provide personalized explanations, feedback, and support for learners, their growing use also poses a profound threat to the validity of educational assessments [1, 4]. By making it exceptionally easy for students to generate fluent and convincing answers, GenAI lowers the barriers to academic dishonesty in ways that traditional safeguards struggle to address [1, 4, 10]. This risk is amplified in unproctored or remote environments, where monitoring is limited and misuse is harder to detect [27].

Importantly, the concern is no longer theoretical: recent studies document that students are already using GenAI for assignments and exams, directly undermining the validity and reliability of assessment results and raising urgent challenges for educational practice and policy [18, 23]. These changes point to a key observation: to ensure resistance to GenAI-related misconduct and to maintain validity and reliability in assessment contexts characterized by potentially heavy LLM use, it is necessary to understand where LLMs diverge from human learners and to characterize their capabilities and limitations across assessment tasks.

Current evaluations of LLM performance on assessment tasks are largely shaped by technical benchmarks (e.g., [3, 25, 14]). These benchmarks provide descriptive statistics that locate LLMs on various scales relative to human learners and provide evidence that LLMs are affected differently from humans by task features such as visual elements or sequential reasoning steps [24, 26]. Yet, little research has examined more generalizable ways of measuring LLM capabilities in relation to human learners. Assessment, by definition, is a proxy that seeks to generalize from sparse samples of student performance (e.g., across time or content). For human learners, the design and interpretation of such proxies have been refined through decades of assessment research and implementation. For GenAI agents, however, it remains far less clear what inferences assessments support.

Mature frameworks from educational measurement – such

[1]In this paper, we use GenAI to refer to generative AI in the broad sense; LLMs to refer specifically to language-oriented models; and chatbots to refer to conversational agents powered by LLMs.

as, but not limited to, Item Response Theory (IRT) [5] – may offer principled ways to assess the capabilities of GenAI. Recent studies [21, 22, 13] have shown that psychometric modeling can be extended beyond its traditional applications to capture systematic differences between human learners and chatbots, mainly for identifying GenAI. Within educational data mining, a central paradigm is that item-level analysis can reveal underlying cognitive processes, providing a foundation for more valid assessment and adaptive learning design [2, 11].

Combining these approaches, our work moves the center of attention from *examinees* to *items*, and its goal is identifying items on which chatbots and humans exhibit differential behavior. Identifying such items serves two important purposes. First, to better understand the dimensions that make tasks easy or difficult for LLMs relative to human learners. Second, to apply these insights to the design of assessments that are better adapted – in terms of validity, reliability, and fairness – to scenarios in which students may work (legitimately or not) with GenAI.

Within psychometrics, there is a collection of methods known as Differential Item Functioning (DIF). DIF refers to situations in which an assessment item functions differently for subgroups of learners distinguished by a characteristic unrelated to the construct being measured (typically a demographic characteristic). In DIF terminology, the baseline group is referred to as the *reference* group, while the group of interest is referred to as the *focal* group. DIF methods go beyond simply comparing overall performance between the reference and focal groups by controlling for student ability, *thereby distinguishing true item bias from general group-level performance differences*.

DIF analysis is widely used in assessment design to flag biased or poorly constructed items, as such items compromise the validity and fairness of the assessment [17]. For example, a mathematics item requiring advanced reading comprehension may disadvantage learners with equivalent math ability but weaker language skills (e.g., second language learners). Methods to detect DIF include non-parametric methods, such as Mantel–Haenszel [16], or parametric ones, such as those based on IRT or logistic regression [15].

The rationale of the current work is to examine whether DIF methods can be useful to identify items on which human learners and chatbots differ. The observation is that chatbots can be referred to as the 'focal' group, while humans are the 'reference' (baseline) group. This is formulated through the following research questions (RQs):

RQ1: *Can DIF techniques identify items that function differently for human learners and chatbots?*

RQ2: *What key characteristics do subject-matter experts identify in items on which chatbots exhibit differential performance compared to human learners?*

To study these questions, we developed, in a stepwise manner, a method that combines DIF analysis with additional item-level criteria and identifies items on which chatbots and human learners show differential behavior. This method was progressively refined and evaluated on human learners and GenAI responses to two assessment instruments taken from two very different contexts: a high school chemistry test administered as a formative assessment, and the quantitative section of a high-stakes psychometric entrance exam for higher education. The GenAI responses were generated using six chatbots (see the Methodology section for details). Following that, subject-matter experts conducted a qualitative analysis of the chemistry DIF items to identify key dimensions that may lead to the differential behavior.

The key contribution of this paper is proposing a theory-inspired and statistically robust method to identify items that exhibit differential behavior for chatbots relative to students, and demonstrating its effectiveness in providing item analytics to those who wish to incorporate GenAI-related considerations into assessment design.

2. PSYCHOMETRIC PRELIMINARIES

2.1 Item–Total Correlation and Rest Score

Item–total correlation (ITC) is defined as the correlation between the score on a single item and the *rest score* for that item, which is the aggregated performance across all the *other* items in the test (also named 'corrected ITC'). It assesses the consistency of an item with the rest of the test, providing a measure of *item discrimination* – how well the item distinguishes between examinees with high versus low overall performance on the test. ITC analysis is used in test design to improve validity and reliability. Following common practice, ITC values of 0.20 or higher are considered acceptable [20]; we adopt this threshold in the present study.

2.2 Differential Item Functioning (DIF)

DIF methods test whether an item functions differently across groups of respondents conditioned on the respondents' *abilities*. Here, 'ability' refers to a respondent's overall proficiency on the instrument and is measured using the per-item rest score, defined as

$$R_{i,-j} = \sum_{k \neq j} X_{ik},$$

where $R_{i,-j}$ is the sum of the respondent i's correct responses across all items excluding the target item j. We use $R_{i,-j}$ as an observed ability proxy throughout the analyses. In DIF terminology, the *reference group* is the baseline for comparison (here, humans), and the *focal group* is the group tested for differences (here, chatbots). For analysis, we denote each response as $X_{ij} \in \{0, 1\}$ for respondent i on item j, where 1 indicates a correct answer and 0 an incorrect one. Conceptually, an item exhibits DIF if two respondents with the same ability, but from different groups, have systematically different probabilities of answering it correctly. Throughout, we adopt a consistent direction convention: **POS**/**NEG** (positive/negative) indicates a chatbot advantage/disadvantage (higher/lower conditional probability of answering correctly than humans at the same ability level).

2.2.1 *Mantel–Haenszel DIF (MH-DIF).*

MH-DIF compares focal and reference groups within discrete strata of the ability proxy and aggregates these comparisons into a

common odds ratio (α_{MH}). Odds ratios less than one correspond to POS (chatbot advantage), while odds ratios greater than one correspond to NEG (chatbot disadvantage). Following ETS guidelines [29], effect sizes are categorized by the magnitude of $|\log(\alpha_{\mathrm{MH}})|$: Category A (*negligible*) if $|\log(\alpha_{\mathrm{MH}})| < \log(1.5)$, Category B (*moderate*) if $\log(1.5) \leq |\log(\alpha_{\mathrm{MH}})| < \log(2)$, and Category C (*large*) if $|\log(\alpha_{\mathrm{MH}})| \geq \log(2)$. MH-DIF is widely used for detecting *uniform DIF*, or differences that are stable across the ability range, and is particularly robust under stratification with limited sample sizes. For more details on MH-DIF, see [19].

2.2.2 Logistic Regression DIF (LR-DIF). LR-DIF provides a more flexible framework that models the probability of a correct response as a function of ability, group membership, and their interaction:

$$\text{logit}\, P(X_{ij} = 1) = \beta_0 + \beta_1 R_{i,-j} + \beta_2 G_i + \beta_3 (R_{i,-j} \times G_i),$$

where $G_i = 0$ for humans and $G_i = 1$ for chatbots, and $R_{i,-j}$ is the per-item rest score used as an ability proxy. Nested model comparisons allow us to test separately for *uniform DIF* (via the main group effect β_2) and *non-uniform DIF* (via the interaction term β_3). In cases where the interaction implies different directions across the ability range, we label the effect as *Sign-change DIF*. From the fitted logistic function we compute likelihood-ratio p-values (m_0 vs. m_1, m_1 vs. m_2), McFadden's $\Delta R^2 = R^2_{m_2} - R^2_{m_0}$ with $R^2_m = 1 - \ell(m)/\ell(m_{\mathrm{null}})$, and at-median odds ratios, which indicate how much more or less likely chatbots are to answer correctly relative to humans at the median ability level after trimming. We adopt $\Delta R^2 \geq 0.035$ as the threshold for a meaningful effect size [9], and use these measures together to detect and characterize DIF effects.

3. METHODOLOGY

This section describes how the psychometric measures above were applied to design a statistical method that identifies items that function differently for humans and chatbots (RQ1), and also the process through which DIF items were subjected to qualitative analysis by subject matter experts to characterize human–chatbot DIF behavior (RQ2).

3.1 Method Design

Task Definition and Modeling. Our task is to develop a statistically principled method that detects and characterizes multiple-choice items exhibiting systematic response differences between human learners and LLM-based chatbots. Adopting the DIF terminology, we refer to humans as the reference group and chatbots as the focal group.

Design Process. To develop a method for identifying true item-level differences between humans and chatbots, we followed a stepwise process, which is outlined in Fig. 1. Below, we briefly describe the key steps (the implementation and results are detailed in Section 4):

Step 1 – DIF Analysis: Given response data from humans and chatbots (see data description below), we applied the two DIF methods defined above (MH- and LR-DIF). These methods allow us to identify items where humans and chatbots with the same ability level differ in the probability of providing a correct response (here, *ability* refers to respondents' overall proficiency on the instrument). We interpret the items flagged in this step as candidate DIF items.

Step 2 – Negative Control Analysis: To control for false positives and validate the overall stability of the DIF analysis, we performed a negative control analysis (Placebo Test [7]). For that, Step 1 was reapplied to 50 null datasets per instrument, where the chatbot group was replaced with random samples of human responses (drawn without replacement). On each null dataset, both MH- and LR-DIF were rerun, and we recorded which items were flagged as DIF to compute their false-positive rates.

Step 3 – Applying Psychometric Diagnostics: Next, we analyzed the items flagged by the placebo test in Step 2 using psychometric validation measures, with the purpose of identifying whether these items have certain psychometric characteristics (e.g., low ITC) that can explain their instability and be used to filter them upfront.

3.2 Instruments and Data

We used two assessment instruments from two very different contexts. The first was a chemistry diagnostic test administered as a formative assessment activity in preparation for the high school matriculation exam. It consisted of 22 multiple-choice items answered by 931 students. The second was the quantitative section of a psychometric entrance exam used for higher-education admissions, containing 40 items with over 4,800 respondents. Both instruments featured multi-modal items with figures, images, and formulas.

To generate chatbot data, we collected responses from six LLM chatbots representing three distinct model families. For each family, we included both a previous version and the most recent release available at the time of study, specifically: OpenAI's GPT-4o and GPT-5.2; Google's Gemini 1.5 Pro and Gemini 3 Pro; and Anthropic's Claude 3.5 Sonnet and Claude 4.5. Via the chat models' web interfaces, we prompted each model to generate a list of final answers to the instrument, which we attached as a PDF file in the prompt. The models typically returned numbered answer lists, which we exported to CSV. This process was repeated 20 times per model, simulating 20 "artificial students" for each chatbot. Overall, for the analysis, we had 120 responses from the six chatbots pooled together. Runs were conducted in separate sessions to prevent memory effects, and variation across responses was introduced by using a non-zero default temperature setting and default parameters set. Since both assessments included multimodal content, it was important that all models supported visual inputs. When a model skipped an item or did not provide a valid option, the response was counted as incorrect (similar to how student responses were treated). The combined human and chatbot responses were then balanced by down-sampling the more abundant data source to construct a dataset at a 1:10 ratio.

The ability distributions of the chatbots and human learners on both instruments are presented in Fig. 2. The bimodal distribution of the chatbots' ability originates from the division between previous and recent chatbot versions (to examine the robustness of the method to model generations, we validated the method reported below also on a subset containing only the previous versions). Table 1

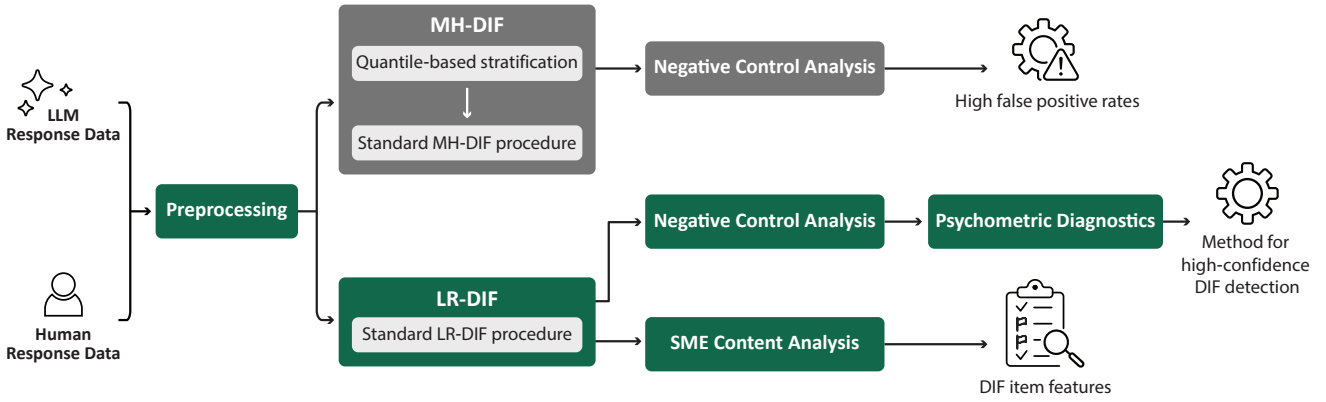

Figure 1: Implemented methodological framework for human–chatbot DIF analysis.

shows the fraction correct of each group on the chemistry items (which were further analyzed by the subject-matter experts). As shown, although the overall success rate of both groups is similar, the chatbots have higher success rates on most items. These sophisticated relations can be handled by the MH- and LR-DIF, as we later demonstrate.

3.3 Qualitative Analysis by Domain Experts

The qualitative analysis was conducted only for the items flagged for DIF by the LR-DIF method in the chemistry instrument. Two subject-matter experts participated in the review process. One expert leads the national team responsible for the annual analysis of the high-stakes chemistry matriculation examinations. The experts received the instrument together with a table summarizing the DIF properties of the flagged items (e.g., POS or NEG; see Table 3) and were asked to qualitatively analyze the DIF items. The two experts independently reviewed, examined, and characterized the items. The two experts then engaged in a joint discussion to compare their evaluations and resolve discrepancies until consensus was reached regarding the characterization of each item.

4. EXPERIMENTS AND RESULTS

This section applies the pipeline outlined in Section 3 and illustrated in Fig. 1. The computational part was applied to the psychometric and chemistry data. The qualitative part was applied to the chemistry dataset, and is described in Subsection 4.5. We then conclude with the resulted procedure for detecting human–chatbot DIF items.

4.1 Preprocessing

The following properties were computed *per item* j. Let $X_{ij} \in \{0, 1\}$ denote correctness for respondent i on item j.

(i) Ability proxy. We defined an *ability proxy* for respondent i as the *rest score* $R_{i,-j}$, the respondent's sum of correct answers across all items *except* item j. Using rest score for respondent i, as opposed to using the global score of respondent i, avoids contamination from the target item and provides a consistent matching variable (i.e., a covariate used to condition comparisons on respondents' overall proficiency).

(ii) Trimming non-overlapping ability ranges. Following DIF analysis guidelines to ensure that both groups were compared only within the overlapping strata of the ability proxy, we removed the human responses in the ability ranges not populated by the chatbots.

(iii) ITC. We computed the items' ITC values, which serve as indicators of item quality, and are later used as a diagnostic filter in the validation stage (see Subsection 4.4). ITC values were computed on the human-only, pre-trimmed responses, as restricting to human data ensures item quality is evaluated relative to the reference group, while using pre-trimmed data preserves the full range of human ability for a fair discrimination estimate.

4.2 RQ1: DIF Technique for Identifying Items on Which Humans and Chatbots Diverge

We applied MH-DIF and LR-DIF on the data, as defined in Subsection 2.2.1, with humans and chatbots as reference and focal groups, respectively.

1. MH-DIF. For each item, we: **(a)** Stratified the trimmed responses by rest score into up to four quantile bins (or fewer when necessary). **(b)** Applied `difMH` to compute the MH statistics retrieved below. **(c)** Retrieved the common odds ratio α_{MH}, the chi-square statistic, and its p-value. **(d)** Flagged items as DIF if $p < 0.05$ and the effect size category (defined in Section 2.2.1) was B or C. **(e)** Assigned direction: $\alpha_{\text{MH}} < 1 \Rightarrow$ POS (chatbot advantage), $\alpha_{\text{MH}} > 1 \Rightarrow$ NEG (chatbot disadvantage).

2. LR-DIF. For each item, we: **(a)** Fit three nested LR models: (i) Ability-only model. (ii) Uniform DIF model: add group membership as a predictor (iii) Non-uniform DIF model: add the ability×group interaction. **(b)** Computed likelihood-ratio test p-values for uniform (p_{uniform}) and non-uniform ($p_{\text{nonuniform}}$) DIF. **(c)** Calculated McFadden's ΔR^2 (fit improvement of the full model over the ability-only baseline). **(d)** Flagged items as DIF if

$$(p_{\text{uniform}} < 0.05 \text{ or } p_{\text{nonuniform}} < 0.05) \quad \text{and} \quad \Delta R^2 \geq 0.035.$$

(e) Summarized flagged items by: (i) Log-odds contrast at median ability. (ii) Odds ratio = exp{log-odds contrast}. (iii) Probability gap between humans and chatbots at median ability. **(f)** Classified direction as POS, NEG, or *sign-*

change if the group effect changed sign at different ability levels.

The items flagged as DIF by both methods are presented in Table 2 and Table 3. As can be seen, MH-DIF flagged a large set of items as DIF, and particularly, a large number of items as POS (chatbot advantages conditioned on ability), including items on which the students scored higher when compared only on raw averages (e.g., items 6-7 in the chem. instrument; see average group scores in Table 1). The LR-DIF was much more conservative, as expected, flagging less items overall. Its more sophisticated modeling enabled it also to identify items with non-uniform DIF (DIF magnitude changes across the ability ranges; e.g., chem. item 12).

These patterns indicate that chatbot–human differences are not only widespread but also vary by item, by direction, and by ability levels, highlighting the diagnostic power offered by DIF analysis. However, in light of the considerable disagreement between the methods (e.g., chemistry item 1, which was flagged as POS by the LR-DIF and NEG by the MH-DIF), we conducted Negative Control Analysis to discriminate true DIF from statistical artifacts.

4.3 Negative Control Analysis

For both datasets, we created $R = 50$ *null datasets* in which the chatbot group (n=60) was replaced by a random sample of human respondents (without replacement). We then reran the MH-DIF and LR-DIF pipelines on each null dataset. Table 4 reports the false-positive counts of items that were flagged at least once under the 50 placebo test runs. Two patterns stand out: **(1)** MH-DIF exhibits diffuse background noise: many items are flagged once or twice, and several reach 8–10% false-positive rates. This noise profile appeared on both instruments, indicating that, at least in our experiment, MH-DIF alone cannot yield reliable DIF signals without additional filtering. **(2)** LR-DIF is far more stable. On the psychometric instrument it produced no null flags across all 50 runs, demonstrating excellent specificity. On the chemistry instrument, LR-DIF was generally stable but showed a small cluster of unstable items (e.g., Item 5).

These findings support LR-DIF as the primary DIF detection method. Yet the presence of a small unstable chemistry items cluster, which showed elevated false-positive rates in the null runs, needs additional item-level analysis and filtering (see Section 4.4).

4.4 Psychometric Diagnostics and Results

We incorporated psychometric diagnostics to analyze and refine the candidate DIF set flagged by LR-DIF. As shown in Table 4, Negative Control Analysis confirmed LR-DIF's stability, though chemistry items 5,9, and 10 exhibited false-positive rates above 10%. To investigate these items further, we examined their ITC, and found that each had very low ITC values (Item 5 = 0.11, Item 9 = 0.08, Item 10 = 0.04). In contrast, chemistry items with ITC values above 0.20 were consistently stable across null runs. These results reinforced ITC as a reliable diagnostic for DIF analysis, using

Table 4: Negative Control Analysis: The items on each *false_positive_count* level (0 omitted).

Counts	Psych.(MH-DIF)	Chem.(MH-DIF)	Psych.(LR-DIF)	Chem. (LR-DIF)
1	6-7, 10, 12-15, 17, 19-21, 24, 27-28, 33, 38	2-3, 6, 9, 13-14, 17-19, 22	–	14
2	9, 18, 22, 29-32, 37, 39	7, 16	–	6-8
3	2, 8, 16, 26, 34	11, 20, 21	–	–
4	25, 35	–	–	–
5	23, 40	12	–	–
6-7	–	–	–	–
8-11	–	–	–	5, 9-10

the standard 0.20 as a cutoff for 'acceptable' [20].

4.5 RQ2: Domain Expert Analysis

As described in Subsection 3.3, the qualitative analysis of the DIF items was conducted by two subject-matter experts who received the instrument and a table that listed the properties of the LR-DIF items, taken from Table 3.

As shown in the Table 3, Items 12, 16, 17, and 19 had POS DIF, meaning that chatbots had *higher* likelihood of answering them correctly than humans at the same ability level. In 12, the system successfully circumvented a common alternative conception according to which sodium chloride is composed of atoms. Instead, it correctly distinguished between the ionic lattice structure of NaCl and the behavior of its constituent particles in solution, emphasizing that dissolution involves the separation of Na^+ and Cl^- ions rather than the breaking of atoms or the formation of atomic species. In 16, which involves a sequence of solution manipulations, the system effectively maintained consistency by monitoring the relationship between solute moles, solution volume, and concentration across several experimental stages. In 17 demonstrated a scientifically appropriate interpretation of the law of conservation of matter by situating the assessment of mass change at the level of the entire experimental system, rather than restricting the analysis just to the original metal. Item 19 further highlighted the system's capacity to apply algorithmic reasoning: the multiple-choice structure facilitated accurate assignment of oxidation states, identification of electron transfer, and correct designation of oxidizing and reducing agents. Collectively, these examples underscore the system's strength in tasks that prioritize rule-governed reasoning and conceptual clarity, where adherence to canonical chemical principles prevents susceptibility to intuitive but scientifically inaccurate interpretations.

In contrast, items 6, 7, 14, and 15, had NEG DIF, meaning that chatbots had *lower* likelihood of answering them correctly than humans at the same ability level. These items place greater demands on visual interpretation, linguistic nuance, and the execution of complex, multi-step procedures. Items 6-7 require learners to interpret partial microscopic models, such as diagrams omitting solvent molecules, or to map symbolic labels (A–C) onto microscopic and macroscopic representations of aqueous solutions. These forms of representation, which depend heavily on implicit visual conventions, posed substantial challenges for the system, whereas students were able to draw upon prior representational.

Questions 14 and 15 illustrate a further point of divergence. Beyond the computational demands involved, these questions also require sensitivity to linguistic nuance, namely the ability to interpret subtle wording, implied meanings, and context-dependent scientific language. For example, in Question 15, students needed to recognize that the statement "the volumes were measured under the same conditions" implicitly justifies the use of proportional relationships between gas volumes and moles according to Avogadro's law. Similarly, Question 14 requires interpreting the phrase "the volume of 1 mole of gas is 25 liters" as applying specifically to gaseous substances in the reaction, while distinguishing between gaseous and liquid species within the balanced equation. Such interpretive demands rely not only on factual chemical knowledge, but also on sensitivity to how scientific information is linguistically framed. Question 14 further involves a multi-stage stoichiometric calculation, proceeding from gas volume to moles, through mole ratios, and finally to mass determination, with each step contingent on the correctness of the one before it. Such extended procedures are particularly vulnerable to intermediate errors in algorithmic reasoning. Question 15 compounds this difficulty, as errors originating in the previous calculation can propagate forward, whereas students often display the metacognitive awareness required to detect and correct inconsistencies in their own work.

Taken together, these findings suggest that the chatbots excel in domains governed by formalized conceptual rules. By contrast, students retain a relative advantage in tasks that demand flexible interpretation of visual representations, sensitivity to linguistic subtleties, and careful monitoring of extended quantitative reasoning processes.

Resulting Method. The conclusion from the experimental results, which both validated the computational process statistically, and evaluated the meaningfulness of the LR-DIF results with subject matter experts on a sample dataset (chemistry), yielded that applying LR-DIF to items with ITC ≥ 0.2 is a reliable method for identifying items that, with high confidence, exhibit differential behavior across humans and chatbots.

5. DISCUSSION

The LR-based DIF approach developed and piloted in this research provides a method and conceptual framework for identifying assessment items that show differential behavior between humans and chatbots. In two assessment contexts and on leading chatbots, we demonstrated that the method provides reliable and stable results. A key observation that DIF, and this research, makes, is that differential behavior is a more nuanced property than merely looking at overall performance gaps between groups, since the DIF analysis controls for ability level, and can identify items as

positive/negative DIF (chatbots over/under-perform learners of the same skill) even if the difference between the mean group performance is in the opposite direction. Our LR-DIF based method offers a modeling that also enables the detection of non-uniform DIF patterns in which either the magnitude or direction of group differences vary across ability levels. Our experiments with both the MH- and LR-DIF highlighted that the MH-DIF, typically the default choice due to its simplicity, produces considerable noise and a high false positive rate. The LR-DIF excelled in this aspect as well. Its downside is its relative complexity and the fact that it typically requires larger sample sizes for stable estimates.

Using the DIF-method to deliver content analytics to the subject-matter experts (RQ2) drove an analysis that yielded interesting insights. As reported in Subsection 4.5, analyzing the POS DIF items, we found that the chatbots managed to circumvent distractors aimed at surfacing alternative conceptions (sometimes referred to as 'misconceptions') commonly held by students. Given that LLMs can be cognitively biased due to their training data [6], which likely included student data also representing wrong or incomplete knowledge [27], the fact that the chatbots dodged these designated 'traps' is interesting, and is in disagreement with previous work that found moderate alignment between LLMs and student misconceptions [12]. On the contrary, experts' analysis of the NEG DIF items revealed that the chatbots underperformed on items requiring visual interpretation and connecting visual and textual information, items that their wording required understanding linguistic nuances, and those requiring performing multi-step problem solving procedures. These findings reinforce previous work about GenAI problem solving in STEM domains [24, 26].

More generally, this research demonstrates a fruitful application of assessment and measurement theory to educational data mining, with the purpose of establishing theory-grounded approaches for understanding GenAI capabilities, and for developing assessment in the GenAI era.

Limitations. This research is the first, to our knowledge, to apply DIF for analyzing chatbot assessment data and, as such, naturally has several limitations. In terms of internal validity, the chatbots' bi-modal performance (fraction correct; see Figure 2) may impact the DIF stratification step, potentially reducing the effective size of the data and thus the method's robustness. The very high ability that the newer models exhibit may reflect data leakage or prior exposure during training, rather than genuine ability, and may falsely cause them to be identified as positive DIF (models outperform humans). A further limitation of our study is that human and chatbot ability estimates were based on a binary scoring model rather than a polytomous one. More nuanced scoring models may capture partial knowledge or intermediate reasoning patterns, and could therefore affect the ability estimates and the resulting DIF patterns. A related limitation is that DIF methods typically assume a relatively uni-dimensional construct and comparison along a common ability continuum [8, 28]. Given the heterogeneous task types included in the instruments, such as visual versus algorithmic reasoning, as well as the use of multiple LLM architectures, some of the observed DIF effects may reflect multidimensionality or within-group variability rather than item-level bias alone. In addition, the SME analysis focused only on LR-DIF flagged items, which were shown to favor either humans or chatbots, and did not compare them against non-DIF items. Such a comparison could provide a clearer interpretation of the features that distinguish DIF from non-DIF items and is left for future work.

The main limitation to external validity is that the results are based on a small number of instruments and specific GenAI tools. Additionally, the SME analysis was conducted only for the Chemistry instrument; extending this analysis to the quantitative reasoning instrument would be important for broadening observed patterns to additional domains.

Contribution and future work. The main contribution of this work is the introduction of a theory-driven and statistically sound method for detecting items that exhibit differential behavior between chatbots and human learners, and the presentation of evidence of its ability to yield meaningful analytics for subject-matter experts who seek to integrate GenAI considerations into assessment design. In future work, we plan to build on this foundation for (1) studying the task dimensions of Human–GenAI DIF items, to better understand the capabilities of this technology, (2) incorporating Human–GenAI DIF analysis into assessment design, and (3) Use DIF analysis to evaluate GenAI progress.

Ethics statement. The research was approved by the Institutional Review Board No. 3331-2.

Data and code availability. The materials needed to reproduce the analyses reported in this paper, including the code, sample data, and prompts used to generate the chatbot data, are available in the GitHub repository: (link)

ABSTRACT

Randomized controlled trials (RCTs) in social or biomedical science often rely on covariate and outcome data drawn from a larger administrative database. For instance, a recent paired, clustered RCT of an online homework platform used covariates (demographics and prior achievement measures) and outcomes (standardized test scores) from the state's educational database. To avoid confounding, typical analyses use only data from randomized subjects, discarding the remainder of the database.

In this study, we re-analyze data from the online homework study, substantially improving the precision of the effect estimates by using data from both randomized and non-randomized subjects. Our estimator does not introduce confounding and relies largely on standard modeling techniques. Specifically, we use observational data to train a random forest model predicting student test scores from student- and school-level covariates, and use it to generate predicted outcomes for students in the randomized schools. Then, we modify the hierarchical linear model from the original analysis by adding the predicted outcomes as an additional regressor, reducing the standard error by 15%—the improvement expected from increasing the sample size by over a third. Since it requires few additional modeling skills and no additional assumptions, this method can be easily adapted wherever auxiliary observational data are available.

Keywords

Causal Inference, Randomized Experiments, Supervised Learning, Hierarchical Linear Models

1. INTRODUCTION

In 2018, WestEd, an educational research agency, began a large-scale randomized field trial of the online mathematics application ASSISTments in 63 schools in North Carolina [3]. The researchers were granted access to the North Carolina student longitudinal data system, from which they drew most of the data used for the evaluation, including demographic and student achievement data from the students in the study—seventh-grade math students in the 63 randomized schools. However, the researchers had access to even more data: demographic, prior achievement, and outcome data from over 65 thousand additional 7th-grade students who attended North Carolina middle schools other than those 63.

The WestEd ASSISTments study is one example of a common phenomenon: covariate and outcome data for a randomized controlled trial (RCT) are drawn from a larger database that also includes data from similar subjects who were not randomized as part of the experiment. Other examples include A/B tests, which draw baseline covariates and outcomes from log data, and clinical trials, which draw baseline and outcome data from patients' medical records. In these examples, researchers have access to big auxiliary observational datasets that are typically discarded or left unused. Granted, pooling data from randomized and non-randomized subjects would introduce confounding—there is no guarantee that subjects in the auxiliary data are comparable to the randomized subjects—and undermine the main motivation for conducting an RCT in the first place.

However, there are other uses for auxiliary observational datasets that maintain the integrity of the RCT. Specifically, [4] suggested using big auxiliary data to train a model predicting experimental outcomes, then using the resulting predictions as additional super-covariates in the "leave-one-out potential outcomes" (LOOP) effect estimator [23]. In studies of educational A/B tests, [4] and [19] showed that this approach can substantially reduce standard errors and increase statistical power, relative to estimators that do not use the auxiliary data. Similarly, [10] found similar results in a secondary analysis of a subset of school-aggregated data from a large, school-randomized effectiveness study, using a different, publicly available outcome than the original study.

These results are promising, but may not be fully convincing to education researchers conducting randomized field trials. First, we are unaware of any published analysis of a large randomized educational effectiveness study like [3] that uses auxiliary data as [4] proposes that uses the study's primary

https://doi.org/10.5281/zenodo.21039716

outcome measure and includes data from the full RCT. Second, the method from [4] has been applied only to single-level data (or to multilevel data aggregated to the school level). In contrast, most large-scale educational efficacy studies use multilevel data, analyzing students as nested within schools. Third, previous studies have focused on the use of auxiliary data within the LOOP effect estimator, a new and unfamiliar estimator with limited availability and applicability, rather than incorporating insights from auxiliary data into familiar models.

In this paper, we present a secondary analysis of the WestEd ASSISTments study incorporating predictions from a random forest model trained on the auxiliary observational dataset composed of North Carolina students who did not participate in the original RCT. Our analysis uses the entire dataset from the original study, along with the study's primary outcome measure, maintains and fully models the multilevel structure of the RCT dataset, and uses hierarchical linear modeling, the dominant approach for analyzing educational field trials, to estimate effects.

We find that, relative to the original estimates published in [3], our analysis reduces standard errors by 15%, roughly equivalent to increasing the number of schools in the study by 38%. Like previous auxiliary data methods, our approach does not introduce confounding and maintains the integrity of the randomization; unlike previous approaches, it is accessible to applied education researchers.

The following section describes the WestEd ASSISTments study of [3]. The next section reviews the relevant methodology, including the methods of [4] and hierarchical linear models. Section 4 describes our analysis, and Section 5 describes the results. Section 6 concludes.

2. THE ASSISTMENTS EFFICACY REPLICATION STUDY

ASSISTments [6] is an internet-based program for mathematics practice and learning, with a focus on middle school students. Teachers may draw from a large corpus of math problems—many drawn from popular curricula and textbooks—to create assignments for their classes. Students receive immediate feedback on the correctness of their work and often have access to hints or other tutoring materials. Teachers can monitor their students' progress and browse useful data summaries for insights into student performance. A large, federally-funded randomized study conducted in Maine [14] showed that randomization to the ASSISTments condition increased student standardized test scores by 0.22 ± 0.07 standard deviations with 95% confidence.

Starting in 2018, WestEd conducted a replication study based in North Carolina, with the goal of extending the previous results to a more diverse population [3]. The study team matched 65 schools into 31 pairs and one triplet based on school-level demographics and prior achievement measures, and then randomly selected one school from each pair and two schools from the triplet for the treatment arm of the study. In those schools, all 7th-grade math teachers used ASSISTments for two academic years, 2018–2019 and 2019–2020, with teachers in the remaining 31 schools continuing business as usual. The original analysis plan was to use the 2019–2020 cohort's end-of-grade mathematics state standardized test to measure efficacy. Unfortunately, due to the COVID-19 pandemic, the 2020 state standardized test was canceled. Fortunately, the study team was able to link the study data with student scores from a year after implementation ended, and estimate treatment effects using standardized test scores from the end of 8th grade. There were two different math standardized tests in 8th grade: the majority took the 8th-grade "end-of-grade" test (EOG08), while a subset of more advanced students took an Algebra I " end-of-course " exam. Following [3], our analysis focuses on the EOG08 exam, under the assumption that treatment assignment did not affect which exams students took. This assumption appears plausible: there was no evidence of differential attrition, and the analysis sample remained balanced on important covariates. All in all, the analysis sample includes 5,991 students, 3,030 randomized to the control condition, and 2,961 randomized to the treatment condition.

To estimate effects, the North Carolina Education Research Data Center granted the WestEd team access to demographic, achievement, and other educational data for all public school students in North Carolina. The study team selected covariates—including prior achievement measures at the student level (a math standardized test at the end of 6th grade, EOG6) and the school level (average 7th-grade scores from prior years), and demographics, including gender, race or ethnicity, and disability and economically disadvantaged status. They also calculated school-level demographics, including 7th-grade enrollment, whether the school was eligible for Title I funding, and the percentages of economically disadvantaged students and students from different ethnic groups. Following standard procedure, no use was made of covariate or achievement data from students in North Carolina schools that did not participate in the RCT.

The study's main overall effect estimate was that randomization to ASSISTments in 7th grade caused an average impact of 0.80 ± 0.64 points on the EOG08 exam (with 95% confidence), corresponding to an effect size (Hedges' g) of 0.10. Since the impact was measured a year after the intervention ended, this represents a persistent effect. See [3] for more details and estimated effects for subgroups.

3. METHODOLOGY BACKGROUND

Statistical analysis of RCTs requires data on the randomized condition, Z—which here we will take as binary, with $Z_i = 0$ if subject i, $i = 1, \ldots, N^{RCT}$ is randomized to the control condition and $Z_i = 1$ if i is randomized to treatment—the outcome of interest, Y, and, typically, a vector of covariates $\boldsymbol{x}$. Covariates $\boldsymbol{x}$, by definition, must be either fixed at baseline, i.e., at the time of randomization, or otherwise known to be independent of or invariant to randomization. Covariates are not always strictly necessary, but they can be invaluable for detecting, testing, and sometimes correcting irregularities in randomization, increasing the statistical precision of the effect estimate, and studying heterogeneity in causal impacts, and hence predicting treatment effects for future subjects or populations.

3.1 Observational Auxiliary Data

Data on Y and $\boldsymbol{x}$ may be available for a separate sample of units that did not participate in the RCT. For instance,

if researchers conducting an RCT drew data on $\boldsymbol{x}$ and Y from a larger database that included, say, historical data or data on current units that were not randomized as part of the study. Along these lines, [20] discussed A/B tests run on ASSISTments E-trials [22], a platform for educational experiments within an online tool for middle-school mathematics practice. In that case, data on the outcome Y, assignment completion, and covariates $\boldsymbol{x}$ (students' prior activities) were available for historical and concurrent users working on different parts of the platform. In this paper, we will re-analyze data from [3], a large educational field-trial testing the efficacy of ASSISTments in a set of North Carolina middle schools in which data on Y, student scores on state standardized tests, and $\boldsymbol{x}$, student demographics and prior standardized test scores, were drawn from the state department of education's longitudinal data system. WestEd, which conducted and analyzed the RCT, was given access to the entire database and thus had access to data from students attending schools that were not part of the RCT.

Auxiliary observational data may seem of little use. In the cases just mentioned, data on the treatment condition Z are not available for students in the observational samples—we presume their experience was akin to the control condition, but this cannot be known. Even if data on the treatment or exposure were available in the observational sample, there would be good reasons not to use them — unlike in an RCT, exposure to the treatment or control conditions may be confounded. Furthermore, there is no guarantee that expected potential outcomes in the auxiliary data represent those in the RCT or even that the conditional distribution of outcomes given treatment status and covariates, $p(Y|Z, \boldsymbol{x})$, is the same in the RCT and observational samples.

On the other hand, auxiliary observational data typically has a much larger sample size than an RCT, and could be helpful in modeling the conditional distribution of Y given $\boldsymbol{x}$, enabling more precise effect estimation. Covariate data in [20] consisted of measurements from the sequence of assignments that students had worked on prior to the onset of the experiment—a complex longitudinal structure that was best modeled by a recurrent neural network that would be impossible or ill-advised to train from a small or moderately-sized RCT sample. The dataset in [3] is high-dimensional, longitudinal—including measurements from multiple successive years—and multilevel, since student data are nested within schools. A model fit only to RCT data would be unable to capture those complexities fully. Moreover, even if RCT data were large enough to support modern ML models, incorporating such a model into a causal effect estimator poses its own challenges, especially when the ML model cannot be guaranteed to be unbiased, as is typically the case.

Recent literature [12, 17, 4, 20] suggests an approach to using big observational data to model the relationship between $\boldsymbol{x}$ and Y and then incorporating that relationship into an RCT analysis without requiring additional untestable assumptions regarding the auxiliary data or the ML model and without introducing any confounding bias. The idea is, essentially, to use the observational data to train a supervised learner predicting Y as a function of $\boldsymbol{x}$; to use that pre-trained model, along with $\boldsymbol{x}$ data from RCT subjects, to generate predicted outcomes $\hat{y}^{obs}$ for RCT subjects; and finally to statistically adjust for $\hat{y}^{obs}$ in an effect estimator. The predictions $\hat{y}^{obs}$ act as a one-dimensional summary of multidimensional covariates $\boldsymbol{x}$, where the summary was designed to extract as much relevant information about Y as possible. Because it is based on RCT covariates $\boldsymbol{x}$ and a model trained on an external dataset, $\hat{y}^{obs}$ are independent of Z—in other words, $\hat{y}^{obs}$ itself is a covariate.

Ideally, $\hat{y}^{obs}$ will be closely correlated with observed outcomes Y within each treatment group—in other words, the auxiliary-data model closely predicts RCT outcomes. A subject's treatment effect, by definition, is the difference between that subject's observed outcome Y_i and the counterfactual outcome, or what *would have* been observed if i had been randomized to the other treatment. Hence, accurate predictions of counterfactual outcomes can increase statistical precision and power when estimating average treatment effects. However, when $\hat{y}^{obs}$ are only weakly correlated with Y, or even anti-correlated, methods described in [4, 20] ensure that the effect estimates remain exactly unbiased and (approximately in small samples, exactly in large samples) no less precise than unbiased estimators that do not use auxiliary data.

Unfortunately, the specific methods recommended in those papers may not always be applicable or practical. [4, 20] recommend adjusting treatment effect estimation with a powerful but somewhat complex method [23, 24] that is currently only available for Bernoulli or paired individually-randomized trials and for paired group randomized trials in which covariates and outcomes are aggregated to the group level [9]. Moreover, these may be unfamiliar or inaccessible to most applied researchers (they are currently implemented only in an experimental `R` package [8]).

3.2 Group-Randomized Trials and Hierarchical Linear Models

Multilevel structures are a hallmark of K–12 education: students are nested within classrooms, which are nested within schools. It is often impractical or impossible to randomize classmates or schoolmates into different educational conditions, so a common technique in experimental education research is to randomize entire classrooms or schools between conditions [11, 15, 3]. In these cases, every student in a single classroom or school is randomized to the same condition, either treatment or control. Educational outcomes tend to be correlated among students within the same school [5], so it is crucial to account for the clustered-randomization design when analyzing clustered RCTs, for instance, by using school-average outcomes to estimate effects [9].

However, researchers often prefer to maintain their data's multilevel structure by using models that explicitly account for within-school correlations. In educational effectiveness research, the most common of these is the hierarchical linear model (HLM) [13]—or, more precisely, a random intercept model—such as:

$$Y_i = \alpha_0 + \boldsymbol{\beta}^T \boldsymbol{x}_i + \tau Z_{s[i]} + \boldsymbol{\gamma}^T \boldsymbol{w}_{s[i]} + \eta_{s[i]} + \epsilon_i \qquad (1)$$

where the subscript $s[i]$ indicates student i's school, α_0 is an overall intercept, $\boldsymbol{w}_s$ are school-level covariates, and $\eta_s \sim N(0, \sigma^2_{scl})$ and $\epsilon \sim N(0, \sigma^2_{ind})$ are school- and student-level regression errors, with variances σ^2_{scl} and σ^2_{ind} esti-

mated from the data. When schools are paired prior to randomization—so that one school from each pair is randomized to treatment, and the other to control, as in [3]—pair indicators are included in $\boldsymbol{w}$.

The coefficient τ represents the estimated treatment effect—the extent to which student scores in treated schools vary, on average, from scores in control schools, conditional on covariates and other school-level factors.

In an HLM such as (1), student scores Y_i are modeled as varying based on their school, via η_s, $\boldsymbol{w}_s$ and Z_s, and individual characteristics $\boldsymbol{x}$. Since treatment is assigned at the school level, the treatment indicator Z has a subscript s and appears in the school-level model of (1). Student scores Y are assumed to be independent conditional on regressors $\boldsymbol{x}$, Z, and $\boldsymbol{w}$ and school errors $\boldsymbol{\eta}$; the school intercepts, in turn, are independent of each other conditional on Z and $\boldsymbol{w}$. Finally, conditional on $\boldsymbol{x}$, Z, and $\boldsymbol{w}$, student scores Y_i and Y_j are independent for students in different schools, $s[i] \neq s[j]$ but correlated with "intraclass correlation coefficient" $\rho = \sigma^2_{sch}/(\sigma^2_{sch} + \sigma^2_{ind})$ for two students in the same school. Hence, HLMs explicitly account for student correlation within schools and are therefore appropriate for school-randomized studies.

4. METHOD

The student-level data used in this study were confidential; hence, all analyses were conducted at WestEd, using Stata.

We followed a two-step procedure to estimate average effects:

1. Use the observational data to train a random forest [2] using baseline covariates to predict student test scores, and use that fitted model to predict test scores for students in the RCT.
2. Estimate average treatment effects by fitting a hierarchical linear model to RCT data, including the predictions from step 1 as a regressor.

The following sections will describe each of these steps in detail.

4.1 Predicting Student Test Scores

As described in Section 2, the research team had access to student-level data from across North Carolina. We used this database to compile an observational auxiliary dataset for training a model to predict students' EOG08 test scores.

First, we identified 65,658 North Carolina middle school students who were not part of the RCT and took the 2021 EOG08 exam. We used anonymized records from all of these students to compile an observational auxiliary dataset. Specifically, we first assembled relevant baseline covariates; since the experiment took place when students were in 7th grade, we restricted covariates to measurements recorded when students were in 6th grade or earlier. These included 6th-grade student background data—age; status as academically gifted, disabled, economically disadvantaged, and/or English language learner; ethnicity indicators; and whether a student was in foster care, homeless, a migrant, and/or connected to the military. We also included students' reading and math assessments from grades 3-6, and 5th-grade science assessments.

We suspected that school characteristics may predict student outcomes, even beyond individual student predictors. Hence, we calculated additional school-level features to include in the random forest. Specifically, we calculated the percentage of students at each school and grade level (grades 3–6) who belonged to each demographic category, as well as the school-grade-level average math, reading, and science assessment scores. All in all, this amounted to 94 student- and school-level features per student.

After compiling the covariates, we fit a random forest regression model to predict students' EOG08 scores. We fit the model using the `rforest` command in `Stata` [21], using the system default tuning parameters (i.e., investigate 9 variables per split and 100 iterations). The random forest predicted posttest scores in the auxiliary data with high accuracy: the out-of-bag prediction R^2 was roughly 0.92.

Finally, we used the fitted model to predict EOG08 math test scores for students in the RCT sample.

As argued above, these predictions, $\hat{y}^{obs}$, can be considered baseline covariates: they were constructed using RCT students' measurements from 6th grade or earlier, and a model fitted to an external sample. Hence, they were invariant to the randomized treatment assignment in the RCT.

4.2 Estimating Treatment Effects

To estimate average treatment effects, we simply re-ran the HLM from the original analysis with $\hat{y}^{obs}$ as an additional covariate, and reported the coefficient on the treatment randomization indicator, along with its standard error.

That is, we compared the original HLM of [3] with an HLM that included $\hat{y}^{obs}$ as an additional student-level predictor (i.e., an additional column of $\boldsymbol{x}$ in 1), and was otherwise identical.

In exploratory analyses, we compared our main estimator with an alternative in which $\hat{y}^{obs}$ *replaces* prior test scores EOG06, rather than supplementing it. That is, we fit an additional HLM that includes $\hat{y}^{obs}$ as a predictor but excludes EOG06. Since both $\hat{y}^{obs}$ and EOG06 are predictors of EOG08, including both in the model may lead to collinearity and inflate standard errors.

5. RESULTS

5.1 Predicting 8th Grade Scores from Observational Data

The random forest accurately predicted EOG08 scores: the out-of-bag root mean squared error was 2.1 points, corresponding to a pseudo-R^2 of roughly 93%. By comparison, an analogous linear regression model had a root-mean-square error of 2.6.

Figure 1 shows a variable importance measure for the top 25 most important predictors in the random forest. In this case, a predictor's importance is the average decrease in mean squared error across splits based on that predictor in the component trees of the random forest. The values in Figure

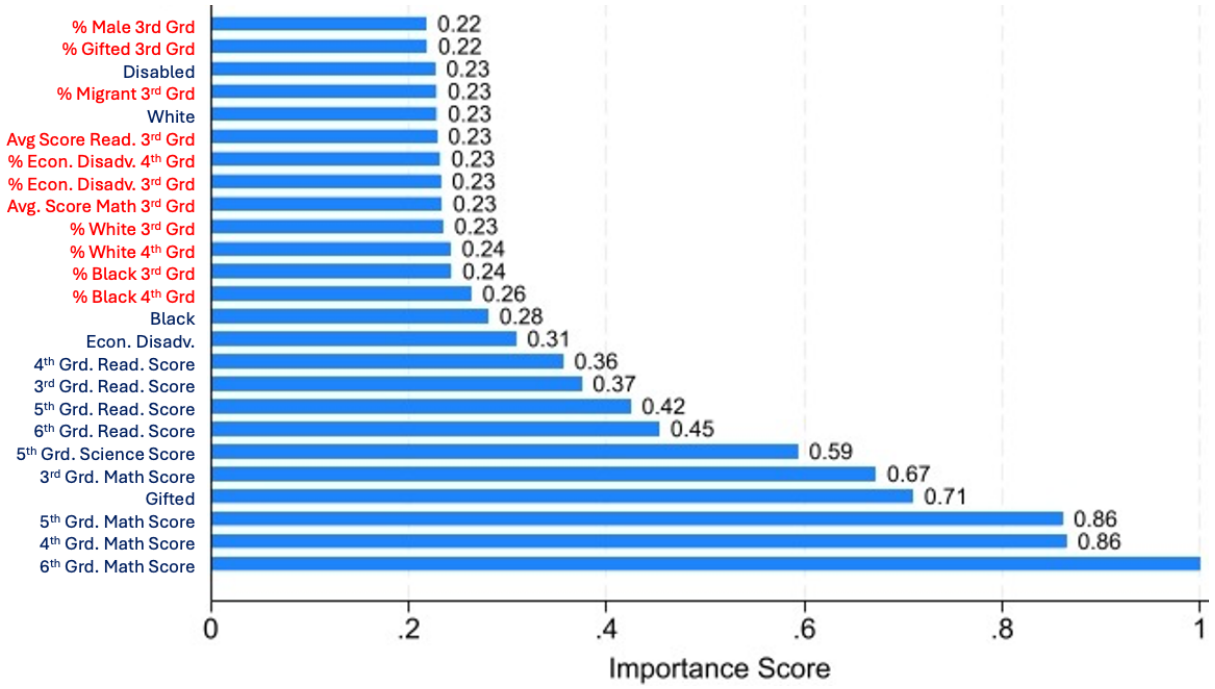

Figure 1: Variable importance for the random forest trained on observational data. Variables in red are school-level aggregates; those in dark blue are student-level. Variable importance is the mean reduction in mean squared error due to a split on that variable, rescaled to 0–1.

1 are divided by the importance measure for the most important predictor, 6th grade math score, so that they range from 0–1 [21].

The three most important predictors, by this measure, are the students' three prior math standardized test scores, followed by previous reading scores and other student-level variables. Most of the remaining top 25 variables are school-level aggregates, including school demographics and prior average exam scores. Notably, only two of the top ten and six of the top 25 predictors appeared in the original HLM (the 6th-grade math score and individual demographics), suggesting that the random forest identified important predictors previously underappreciated. Specifically, students' prior math scores from 4th and 5th grade and their prior reading scores seem to play an important role.

5.2 Estimating Effects

Table 1 and Figure 2 show estimated effects from the original model from [3] alongside two modified models: with $\hat{y}^{obs}$ as an additional predictor and with $\hat{y}^{obs}$ replacing students' prior scores, EOG06.

Including $\hat{y}^{obs}$ as an additional predictor decreased the standard error by 15%, from 0.317 to 0.270. Since standard error tends to be inversely proportional to the square root of the sample size, decreasing the standard error by this amount is roughly equivalent to increasing the sample size by 38%, a substantial improvement.

If $\hat{y}^{obs}$ replaces EOG06 in the HLM (i.e., if EOG06 is dropped from the model), the standard error decreases even more, to 0.265, a decrease of over 16%, corresponding to a 44% increase in effective sample size.

Table 1: Estimated effects, standard errors, effect sizes (Hedge's g), and p-values for three HLMs: the original as reported in [3], one with $\hat{y}^{obs}$ added as a predictor, and one with $\hat{y}^{obs}$ replacing EOG06.

Model	Eff.	SE	Hedges' g	p
Orig.	0.80	0.317	0.10	0.012
Orig.+$\hat{y}^{obs}$	0.68	0.270	0.08	0.011
Orig.+$\hat{y}^{obs}$-EOG06	0.68	0.265	0.08	0.011

6. DISCUSSION

In re-analyzing data from a recent large educational efficacy study, this paper described a method for incorporating data from across the state, including students from both randomized and non-randomized schools. The method combines insights from recent statistical literature [4] with more conventional hierarchical linear modeling, and captures many of the advantages of both: it uses observational data to increase statistical power and precision without introducing confounding bias, it uses familiar and flexible methods that are accessible to applied education researchers, and it fully models the hierarchical structure of the data. In the analysis presented here, incorporating observational data was equivalent to increasing the sample size by over a third.

The results presented here represent the beginning of our reanalysis of the North Carolina data. Future research will apply the method described here to estimate the effect of randomization on the more advanced "end of course" exam,

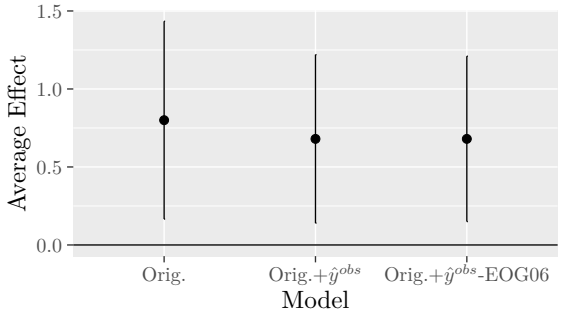

Figure 2: Point estimates and 95% confidence intervals from three HLMs for the average treatment effect in the North Carolina Assistments efficacy study.

as well as on students' choice to take one exam or the other—did assignment to the treatment condition cause some students to take the more (or less) advanced 8th grade class? We also hope to delve deeper into the random forest model discussed in Section 5.1 to better understand its superiority to more parsimonious linear models. Finally, we hope to use the method discussed here to estimate subgroup effects; hopefully, the additional power will enable the investigation of smaller subgroups.

In general, we hope that future research will apply this method to other datasets to better understand how often and by how much incorporating auxiliary data can improve statistical power. Ideally, the availability of auxiliary data can help researchers conduct smaller experiments—first, they will need a tool to prospectively estimate the power gains from auxiliary data, perhaps akin to [7].

Overall, the larger the (absolute) correlation between $\hat{y}^{obs}$ and the outcomes Y in the RCT sample, the greater the resulting gains in precision will be. In the worst case, when the correlation is low or zero, incorporating $\hat{y}^{obs}$ into a causal estimator may increase standard errors slightly—like adding any noise covariate to the model—and will not cause bias.

These considerations imply that choosing a better-performing predictive model can lead to more precision gains. In this study, we used the random forest, which has shown competitive performance in previous research [10], and is relatively easy to implement, but a better model would have led to even greater precision gains. Fortunately, auxiliary data can be used to both train and select the predictive model: since it is a completely separate dataset from the RCT, it can serve as a sandbox for attempting various predictive models and choosing between them. However, the model's performance in the RCT sample, where it counts, may be substantially lower than in the auxiliary data; we are actively researching and developing transfer learning models that may mitigate this issue.

Since precision gains are driven by the correlation between $\hat{y}^{obs}$ and Y, and not predictive accuracy, our approach, properly tweaked, may work even if the outcome in the auxiliary data is not the same as in the RCT, but is correlated. Our first attempts in this direction were not encouraging [18], but the work is ongoing.

The method described here is an example of data fusion, a growing interest among quantitative researchers in integrating observational and randomized data [1, 16]. These include methods for extrapolating RCT results to other populations, identifying important moderators or mediators, as well as methods, like the one discussed here, for increasing precision and power. Data fusion is an exciting new direction in statistical causal inference, and it is especially relevant to educational data mining. We hope that as more methods and datasets become available, incorporating randomized and non-randomized data into unified analyses will accelerate the science of learning.

ABSTRACT

Classroom speech and lectures often contain named entities (NEs) such as names of people and special terminology. While automatic speech recognition (ASR) systems have achieved remarkable performance on general speech, the word error rate (WER) of state-of-the-art ASR remains high for named entities. Since NE are often the most critical keywords, misrecognizing them can affect all downstream applications, especially when the ASR functions as the front end of a complex system. In this paper, we introduce a large language model (LLM) revision pipeline to revise incorrect NEs in ASR predictions by leveraging not only the LLM's world knowledge and reasoning ability but also the available phonetic and semantic context. We also introduce the NER-MIT-OpenCourseWare dataset, containing 45 hours of data from MIT courses for development and testing. On this dataset, our proposed technique achieves up to 30% relative WER reduction for NEs.

Keywords

classroom speech analysis, contextual ASR, named entity transcription, LLM revision

1. INTRODUCTION

In the past several years, automatic speech recognition (ASR) performance has improved significantly by scaling data and model size. Whisper [24], which was trained on 765K hours of speech, has achieved remarkable performance, achieving a WER of 2.7% on the standard Librispeech clean corpus and an average of 12.8% across popular speech datasets [24]. However, Whisper (large-v3) still falls short in recognizing named entities (NEs). For instance, it has a WER of 28.9% for persons and 19.6% for organizations in the contextual ASR benchmarking dataset ConEC [12]. Since classroom and academic speech often contains NEs, the inability to recognize them correctly can cause downstream problems in various educational applications, such as topic modeling of curricula [25, 28, 2], interactions with real-time educational agents [9, 16], and more.

Humans, on the other hand, have the ability to reason and relate different NEs based on knowledge and local context. For example, students can use lecture slides to map the NEs in the speech from a lecture video to the content in the slides, using both semantic as well as phonetic information. Since NEs relate to events, persons' names, products, etc. which often depend on local context and change over time, the solution of retraining a model with new paired speech-text data is expensive, and hard to scale.

Contributions: (1) We propose a novel approach (see Fig. 1) that utilizes an LLM to revise incorrect NEs in ASR transcripts. Specifically, the LLM receives predictions from the ASR and filtered information from the local context, which contains similar-sounding NEs and sentences that include these words, and uses this information to revise the ASR predictions. In contrast to prior works on LLM revision of ASR, our method harnesses combines LLM-based reasoning and world knowledge with explicit phonetic and semantic context, without needing to be trained on a specific NE list. The method is interpretable because the LLM explains why it makes certain revisions, unlike other attention-based approaches that only output the revision without any explanation. (2) We demonstrate that our proposed method works effectively with different LLMs, ranging from closed-source to open-source models and across various sizes. (3) Finally, we introduce the MIT-OpenCourseWare NER contextual dataset, which includes both speech-text pairs and local contexts[1].

2. RELATED WORK

Fine-tuning Speech Foundation Models for Classroom Speech: The past few years have seen growing interest in fine-tuning speech foundation models (e.g., wav2vec2 [4] and WavLM [8]) for classroom-specific recording conditions [27, 3]. While this approach can increase the average transcription accuracy, it does not focus on named entities in particular. Even though NEs may occur more frequently in classroom speech than in everyday speech, they still make up only a small fraction of the overall audio recording; hence, the ability of fine-tuning to improve NE recognition performance is limited. In contrast, our proposed method is "zero-shot" in the sense that it uses an pre-trained LLM's ability to to fix errors, given enough phonetic and semantic context, without needing a large dataset for parameter tuning.

Biasing: A common way to improve NE recognition is by biasing the ASR toward a list of predefined words. This can be implemented with shallow fusion [13, 11, 30, 18] whereby, during inference, the ASR prediction is influenced by a contextual language model with a certain weight. In practice, such systems are sensitive to the weight parameter. More powerful are biasing approaches that combine the context and acoustic information more tightly, e.g., with a neural network that encodes contextual information and is trained jointly with the ASR system [23, 7, 26, 10]. One of the difficulties in biasing approaches is that performance often decreases as the number of approved NEs grows. Our proposed solution addresses this issue by selecting only the NEs in the context that sound similar to those in the ASR prediction.

LLM-based ASR revision: During the past two years, there has been significant interest in developing LLM-based methods to revise ASR hypotheses [20]. For instance, [22] use language model rescoring followed by an LLM in zero-shot fashion to revise the ASR hypothesis based on a ranked list of most likely candidates. [17] also use an LLM to revise the ASR hypotheses based on the most likely candidates but additionally impose constraints so that the revised prediction is similar to the original one in terms of Levenshtein distance. Neither of these methods harness semantic context or phonetic similarity. Most similar to ours is work by [29], which combines phonetic and contextual information to revise NEs in ASR transcriptions. However, in contrast to our method, which is training-free and generalizable to different vocabularies, their approach requires training a masked language model on a fixed set of NEs to detect NE mistranscriptions.

3. PROPOSED METHOD: PHONETIC & CONTEXTUAL LLM REVISION

We propose a novel method of using an LLM's reasoning abilities to revise ASR predictions by harnessing *contextual* as well as *phonetic* information on named entities in both the speech and the available context. The method consists of several steps. First, (1) speech is transcribed using an ASR model (e.g., Whisper). Next, (2) NEs are extracted from both the ASR predictions and the context documents using an off-the-shelf NE recognition tool. The context can be any text document related to the speech. For instance, when transcribing lectures, the context might include slides or reading lists. Due to the large number of words in the context, (3) the NEs are selected from the context only if they share the same entity type (e.g., person, organization) and sound similar to the NEs in the ASR predictions. Finally (4), an LLM analyzes the ASR predictions and their NEs, as well as the NEs in the context and the sentences containing them. It uses this information and a detailed prompt of instructions (see Fig. 3) to produce a revised prediction.

4. DATASET

As existing datasets for contextual ASR are very limited and often tailored to specific industry settings (e.g., earnings calls), we collected our own dataset on topics of wider scientific and educational interest. In particular, we constructed a new dataset, called NER-MIT-OpenCourseWare, based on content from MIT OpenCourseWare. We chose this educational repository as a basis for our dataset because of the availability of detailed context documents along with high-quality transcriptions of the speech content.

For the test set, we used the lectures from an undergraduate course on animal behavior, offered in Fall 2013 from MIT OpenCourseWare, containing 25 lecture audio recordings totaling 17 hours of audio. The test set labels contain approximately 121K words, while the context consists of 46K words. The ground-truth transcriptions contain 1.2K NE words, and about 66% of these words appear in the slides. Examples of lecture slides are shown in Figure 2.

For the development set, we chose an undergraduate course about brain structure, offered in Spring 2014. The course has 35 lectures, but we only use the first 3K utterances to enable faster execution. The labels contain approximately 32K words, while the context includes 14K words from six lecture slides. There are 0.2K NE words in the development set, and around 60% of these words appear in the slides.

We used BeautifulSoup[2] to download the audio, video, and lecture content; pdfplumber[3] to convert the ground-truth transcripts and the slides into text files; and spacy (specifically "en_core_web_lg") to remove unwanted characters and split the transcripts into sentences. The slides contain images, math equations, and other elements, making them noisy. We used pydub[4] to extract audio (flac) from video (mp4) and convert the audio to mono with a sampling rate of 16KHz. Since each audio file has a duration of 30-60 min, we used fairseq [19] to segment each audio into utterances corresponding to the sentences identified by the spacy model.

5. EXPERIMENTS

Using NER-MIT-OpenCourseWare (Sec. 4), we conducted experiments to assess the benefits of the proposed method (Fig. 1) to improve ASR transcription accuracy of NEs, while hopefully keeping the transcription accuracy of non-named entities (NNEs) unchanged. As our method focuses on filtering relevant information in the context using contextual and phonetic cues before feeding it to the LLM, we compare against three strong control conditions: (1) no LLM, just phonetic matching of the predicted NE with a randomly chosen similar sounding word of the same entity type from the context; (2) giving the revision LLM the entire context document corresponding to a given utterance (not just the filtered relevant entities); and (3) first using an LLM to summarize the context, and then providing the summary to the revision LLM.

5.1 Implementation Details

For the first-stage ASR, we use Whisper large-v3. We choose Flair [1] ("ner-english-ontonotes-large"), for named entity recognition (NER) due to its speed and high accuracy on standard NER benchmarks. To detect whether two words sound similar to each other, we use Double Metaphone [21], which is a popular rule-based algorithm that converts words into phonetic codes that is useful for detecting similar sounding words and name searches [5]. Specifically, Double Meta-

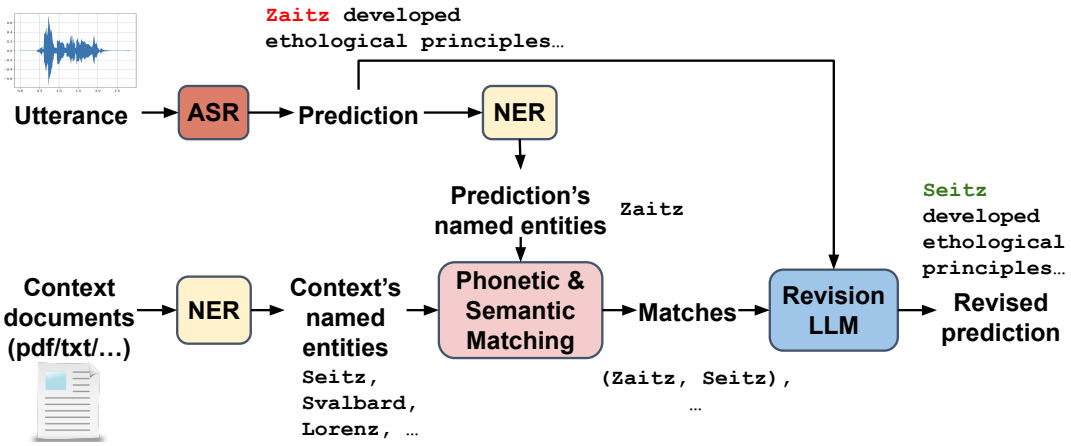

Figure 1: Proposed method of combining phonetic and contextual information to revise named entities in ASR predictions.

Table 1: Comparison of named entity (NE) word error rates (WER) (%) and non-named entity (NNE) WER (%) across methods using Whisper-large-v3 as the ASR.

Revision Method	LLM	NE	NNE
None	–	32.3	7.0
Phonetic matching	–	25.3	7.0
Full context	GPT-4o-mini	43.4	7.1
	GPT-4o	30.6	7.0
	Llama-3.1-70B	32.6	7.2
Context summary	GPT-4o-mini	38.6	7.1
	GPT-4o	54.2	7.1
	Llama-3.1-70B	47.4	8.2
Proposed method	GPT-4o-mini	22.7	7.0
	GPT-4o	22.9	7.0
	Llama-3.1-70B	24.8	7.2

phone outputs one primary and one alternative phonetic code (for names that may be pronounced in different ways). In our proposed method, we defined that two words sound "similar" to each other if either their primary phonetic codes or equivalent or their alternative phonetic codes are equivalent. We note that the use of Double Metaphone could conceivably be "swapped out" for another phonetic matching system (e.g., one based on multimodal LLMs with shared semantic and acoustic embeddings) to work for other languages. We leave this to future work.

Similar to prior contextual ASR research [12], we focus on eight specific NE types: PERSON, ORG, GPE, LOC, PRODUCT, EVENT, NORP, and FAC. We manually verify the NEs in 500 sentences from the test set and measure set-based evaluation recall, ignoring multiple occurrences of the same NE in a sentence, as the LLM replaces all instances of the same NE in the sentence. The precision of Flair is 96%, and the recall is 86%. Since manually labeling NEs in the dataset is expensive, and Flair's recall rate was reasonably high, we use Flair's detected NEs as a basis for computing WER.

Table 2: Comparison of named entity (NE) and non-named entity (NNE) WER (%) across speech recognition systems utilizing GPT-4o-mini in our proposed method.

ASR	Params	Before revision		After revision	
		NE	NNE	NE	NNE
Whisper-sm	244 M	39.3	9.4	29.5	9.4
Whisper-me	769 M	36.0	8.0	26.8	8.0
Whisper-la	1.54 B	32.3	7.0	22.7	7.0
Canary-1B	1B	36.6	8.3	26.8	8.3

For the revision LLM, we compare Llama3-70b-8192 (via Groq API), GPT-4o-mini API, GPT-4o API , and Meta-Llama-3.1-70B (using bitsandbytes quantization), running locally on a single A100 GPU (80GB) with vLLM [15]. We draw inspiration from [6] to design the prompt. Our prompt (see Fig. 3) is designed to ensure that the LLM revises NEs without altering other words and applies reasoning. The asr_confidence_threshold used in the prompt was optimized on the development set.

For the summarization task (in control condition 2), we use GPT-4o-mini with the prompt: "Summarize the following context concisely while ensuring all named entities are preserved. Include a sentence for each named entity, using only alphabets and digits. Context:{context}".

5.2 Results

As shown in Table 1, the proposed method demonstrates improved accuracy compared to the original Whisper predictions, regardless of which LLM was used. In particular, the proposed approach reduces the WER of NE to 22.7% (corresponding to a 30% relative WER reduction) while maintaining the NNE WER at 7%. Phonetic matching of NEs to the context (control condition 1) is also useful and decreases the WER to 25.3%. In contrast, when using an LLM with the full context (control condition 2) without any filtering, the WER actually increases from 32.3% to 43.4%. This could be due to the long prompt input, which causes the LLM to hallucinate: a follow-up analysis of the animal behavior course test set revealed that the full-context condition

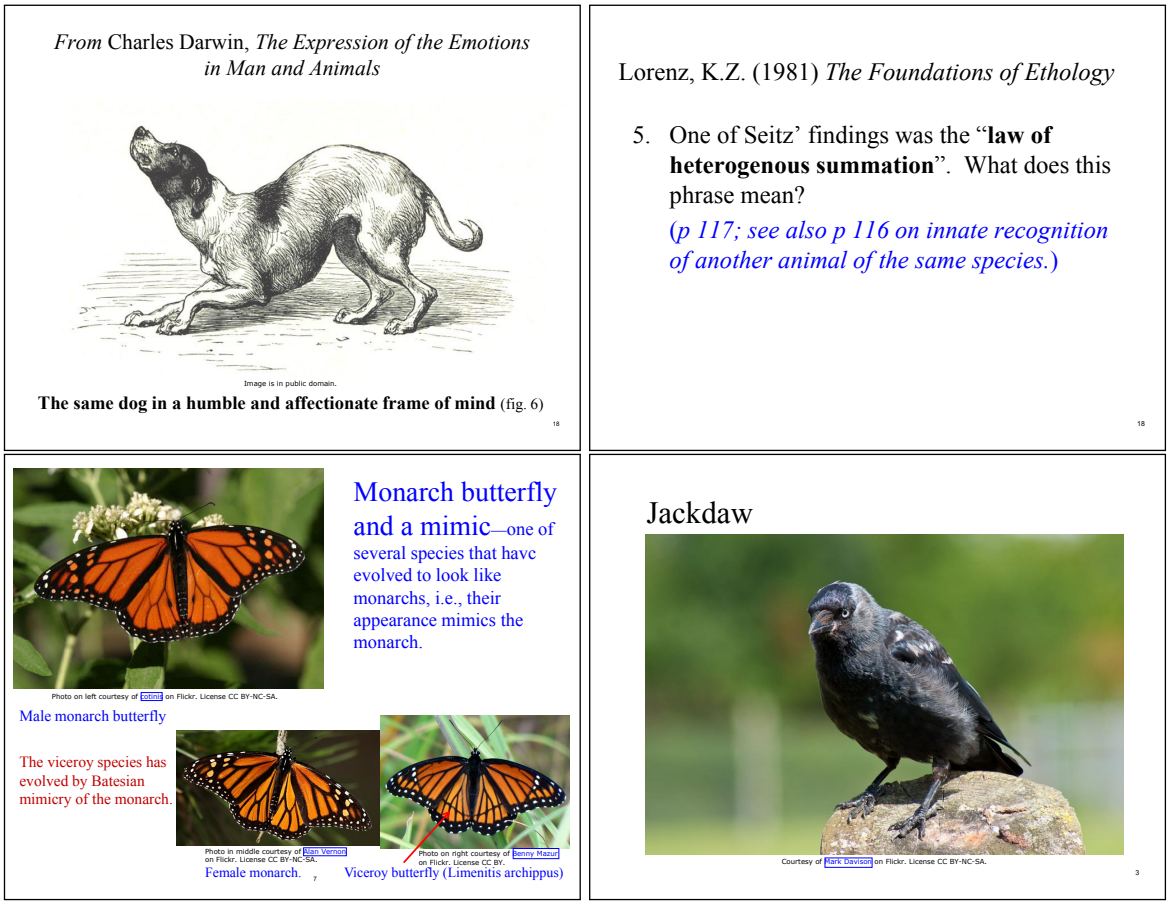

Figure 2: Examples of NER-MIT-OpenCourseWare slides.

using GPT-4o resulted in statistically significantly longer revisions, on average, compared to the proposed method ($t(9426) = 4.11, p < 0.0001$). Control condition 3, which uses a summary of the full context, is also ineffective, as the WER increases from 32.3% to 38.6%. Together these results indicate that, despite being trained on large amounts of text data, the LLM's world knowledge and linguistic reasoning are insufficient to improve the ASR accuracy of NEs. Instead, both a filtered context as well as explicit phonetic information are necessary to enable the LLM to improve NE transcription.

As a follow-up analysis, we also computed the WER of the proposed method (using GPT-4o-mini and Whisper) on named entities (NEs) not included in the context documents: it is 23.6%. This is only slightly higher than the overall WER on NEs (22.7%), and it is still substantially lower than the WER on NEs with just Whisper alone (32.3%). This suggests that the proposed method is unlikely to do harm, even if its benefits are more pronounced on NEs that are contained in the context.

Our proposed method also demonstrates its effectiveness across different LLM models, such as the large, state-of-the-art GPT-4o and the robust open-source Llama-3.1-70B, as shown in Table 1. For a powerful model like GPT-4o, utilizing the full context results in a slight WER reduction, from 32.3% to 30.6%, as indicated in Table 1. However, with our proposed method, the WER is significantly reduced to 22.9%.

To evaluate the effectiveness of the proposed approach over different ASR systems, we conducted experiments with Whisper (small, medium, or large-v3), and Nemo Canary-1B [14], another state-of-the-art ASR model. As shown in Table 2, our method generalizes well across different speech models: With Canary-1B, the NE WER is reduced from 36.6% to 26.8%. Similarly, the NE WER is reduced from 39.3% to 29.5% with Whisper small and from 36.0% to 26.8% with Whisper medium.

Finally, we also experiment with a simpler version of the prompt that omits the extra guidelines contained in the second, third, fourth, and fifth bullet points of Figure 3. This shortened prompt's results are reported in Table 3. As shown, both the full prompt and the short prompt perform well with GPT-4o-mini, while the open-source Llama-3.1-70B achieves better performance with the full prompt at 24.8% compared to the short prompt at 32.3%. This indicates that the paid API GPT-4o-mini may be more robust and have better reasoning capabilities than the open-source Llama-3.1-70B in this case. The open-source model appears to require more detailed instructions to achieve good results, whereas GPT-4o-mini can perform well without them.

Speech recognition may incorrectly capture named entities due to similar-sounding words or uncommon entities in training data. The named entities and their probabilities are provided below as "Named entities probability" in the format: entity : probability. Review the prediction's named entities. For each entity whose probability is below asr_confidence_threshold, or missing, please complete the following steps:

- Examine the context to determine what the similar-sounding entity refers to, and analyze the sentence to understand what the ASR-predicted entity refers to. Check if (1) both refer to the same thing, (2) the difference is likely due to an ASR transcription error, (3) the replacement improves accuracy, preserves the original sentence's meaning, and fits naturally within the sentence. If yes to those 3 criteria, then replace the ASR-predicted entity with the similar-sounding entity.
- Make sure to treat each named entity as a cohesive unit when evaluating or replacing. Do not modify individual words separately in a multi-word entity.
- If no suitable similar-sounding entity exists, leave the entity unchanged.
- Do not delete any words in the entity that are absent from the context.
- Keep all other words, punctuation, and formatting unchanged.

The context includes similar-sounding entities and sentences containing these named entities. The revised prediction should start with << @ and end with @ >>
Context: {context}
Speech recognition prediction: {preds}
Named entities probability: {ent_prob_dict }

Figure 3: ASR revision prompt given to the LLM. In an ablation analysis, we omit the second, third, fourth, and fifth bullets points.

5.3 Examples

The ground-truth transcript (converted to lower case) of one utterance is, "now this is a difficult concept but let me try to go through it anyway because seitz was very important in working out some of the principles of ethological investigation and the principles of ethology that lorenz was talking about". Canary 1B transcribed it as, "now this is a difficult concept ... zeitz ... lawrence ..." (where the ellipses indicate correctly transcribed words that we omit for brevity). Whisper transcribed it as, "now this is a difficult concept... zaitz ... lawrence ...". After LLM-based revision with the proposed method, both Canary and Whisper correctly transcribed it as, "now this is a difficult concept ... seitz ... lorenz ...".

In another utterance, the ground-truth transcript is, "one of those students became very well known margaret mead". With phonetic matching (control condition 1), the NE was replaced with a randomly chosen similar-sounding NE, resulting in "... margaret mit". With our proposed method (using GPT-4o-mini), however, the ASR transcript is correctly transcribed as, "... margaret mead".

5.4 Run-time Cost

Extracting NEs takes about 0.013sec per utterance (averaged over 9427 test utterances). Revising each ASR prediction using GPT-4o-mini takes about 1.2sec (averaged over 750 test utterances with NEs).

Table 3: Named entity WER (%) and non-named entity WER are evaluated using the full prompt or the short prompt.

Method	Revision LLM	NE (%)	NNE
Full prompt	GPT-4o-mini	22.7	7.0
Full prompt	Llama-3.1-70B	24.8	7.2
Short prompt	GPT-4o-mini	22.7	7.0
Short prompt	Llama-3.1-70B	32.3	7.0

6. CONCLUSIONS

We introduced a novel method to revise predictions from ASR using an LLM. Specifically, we employ a phonetic and contextual matching component to select NEs from the context that are most relevant to those in the ASR prediction. We compare our proposed method to strong LLM controls that use the full context or a context summary, as well as a phonetic matching baseline, and show that our method achieves superior performance – up to 30% relative WER reduction on a new and challenging test set based on MIT OpenCourseWare lecture series. We focused primarily on NEs since their definitions are standardized, and tools for NER are readily available. However, the method could be extended to revise rare words with the development of rare word detection models. Furthermore, the method could be expanded to integrate visual information, such as image captions or optical character recognition, so as to better harness available context.

Mining how curiosity spreads in student-led online discussions

Farhan Ali

Nanyang Technological University
farhan.ali@nie.edu.sg

ABSTRACT

Curiosity is central to learning and human development, yet it is typically studied as an individual psychological state. Using a social cognitive lens, this study examines whether and how curious behaviors are transmitted socially in student-led online discussions. We first constructed and validated a new large-scale dataset from a student-driven educational forum on Reddit (full dataset: ~55,000 users, ~39,000 posts; ~667,000 comments). Curiosity was operationalized as question-posing using a 2×2 question type taxonomy involving open/closed and possibility thinking dimensions. Generalized linear models revealed clear social transmission effects: question-posing in comments generally increased questioning in subsequent replies, regardless of question type. Parallel mediation analyses involving two categories of discussion features - cognitive and socio-affective - uncovered pathways of transmission of curiosity involving social endorsement, cognitive alignment, and selective mimicry. These findings advance the field by demonstrating that curiosity is socially transmitted, highlighting its contingent spread, and providing insights into how educators and platform developers can intervene and design features to steer discussion trajectories. Our research further contributes descriptively via a new taxonomy of question-posing and the dissemination of a new online discussion corpus useful for future research.

Keywords

adolescents, curiosity, online discussions, Singapore, Reddit, question-posing

1. INTRODUCTION & BACKGROUND

Curiosity is central to learning yet often treated as an internal state. There is a need to broaden our understanding in order to better foster curious learners. Drawing on social cognitive theory, we examine how curiosity, expressed through question-posing, spreads in peer online discussions where there are rich intersections of formal learning, informal learning, and community inquiry. Using large-scale data from an education-oriented Reddit community, data mining, and quantitative modeling, we investigate curiosity's transmission patterns and mechanisms in authentic student digital environments.

1.1 Social cognitive theory

Social learning theory conceptualizes learning as inherently social, shaped by observing others' behaviors and their consequences. Social cognitive theory further emphasizes cognitive and motivational processes that determine whether observed behaviors are adopted [3, 4]. A central process is the transmission, or diffusion, of thoughts and actions across individuals. The proposed mechanisms include imitation, modeling, and vicarious reinforcement, whereby behaviors perceived as rewarded are more likely to be replicated. Importantly, transmission is thought to be selective: individuals evaluate relevance and value before adopting the observed behaviors. In education, parallel theoretical traditions such as social constructivism highlight knowledge as co-constructed through dialogue and collaboration [20].

1.2 Curiosity

Curiosity - the desire for new information and knowledge [16] - is a foundational driver of learning and development and predicts important outcomes such as academic achievement, well-being, and longevity [22, 24, 27]. Yet contemporary schooling is often argued to dampen curiosity [7], with cross-cultural evidence indeed documenting systematic declines from elementary to secondary years [11]. Understanding how curiosity can be triggered and fostered is, therefore, an important educational challenge.

Most research conceptualizes curiosity as an intrapersonal state. However, curiosity is also expressed behaviorally in social contexts, most visibly through question-posing, a behavior widely studied in curiosity research in education [7, 13]. A question is not merely a private attempt to resolve an information gap; it signals to others what is worth asking, how to ask, and whether such behavior is socially valued. In this sense, curiosity becomes embedded within a social learning ecology, with potential to spread or dissipate depending on peer responses and contextual cues.

While question-posing is often used as an indicator of curiosity, questioning may not all reflect intrinsically motivated curiosity. Drawing on a goal-systems perspective, it is useful to distinguish between curiosity as a motive (ends) and curious behaviors that serve diverse goals (means) [23] such as performance-enhancement or tension-reduction. This distinction is especially relevant in large-scale online data, where inferring internal motivation is difficult without additional contextual or self-report measures. Accordingly, we follow framing by Szumowska & Kruglanski [23] to operationalize curious behaviors (as opposed to curious motivations) with question-posing. Importantly, in our context, questions are voluntary rather than teacher-prompted and non-evaluative with no immediate benefit, making them a meaningful indicator of momentary curious behaviors in authentic peer learning interactions.

Emerging evidence suggests that curiosity may indeed be socially transmissible from human to human in classroom settings [2], and even from robot to human in experimental settings [9]. However, the extent, mechanisms, and boundary conditions of curiosity transmission, particularly in authentic, peer-driven digital environments where many adolescents now regularly interact, remain

Farhan Ali. Mining how curiosity spreads in student-led online discussions. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) Proceedings of the 19th International Conference on Educational Data Mining, Seoul, Republic of Korea, June, 2026, pp. 500–507. International Educational Data Mining Society (2026).

insufficiently understood. An important question is the nature of the transmission. Transmission may be broad, where exposure increases questioning generally, or narrow, where specific question types are preferentially replicated. Distinguishing these forms clarifies whether curious behaviors spread as generalized activation or subtype-specific processes, informing strategies for interventions or nudging on online platforms or by instructors.

1.3 Educational context: Reddit online discussions

Digital communities such as Reddit provide a valuable setting for examining curiosity in authentic peer interaction. Reddit hosts sustained, community-driven discussions spanning personal, academic, and social topics, leaving behind rich textual traces suitable for large-scale educational research. Prior studies have used Reddit data to illuminate important educational issues, including impact of COVID-19 [26] and the emergence of ChatGPT [18] . The platform's affordances also align well with a social learning perspective: for instance, upvotes function as social reinforcement, threaded replies make interaction paths explicit, and norms such as quoting or referencing can signal uptake and engagement.

Within this Reddit context, curiosity can be operationalized through question-posing, a visible indicator that researchers have emphasized as being important [7, 13]. Building on prior educational research and recent frameworks distinguishing open/closed and possibility-oriented questions[1], we propose crossing these dimensions to derive four nuanced question types, enabling automated analysis of how curiosity is expressed and potentially transmitted in adolescent online discussions.

To understand how curiosity spreads, discussion patterns must be analyzed. Prior work integrating social learning and community-of-inquiry perspectives identified three interdependent features [10]: cognitive presence (collective meaning-making through discourse), social presence (interpersonal and affective expressions), and teaching presence (directed facilitation toward learning goals). In adolescent-driven communities with minimal adult moderation, cognitive and social presence are especially central. This framework highlights how epistemic contributions (e.g., explanations, meaning) and socio-affective signals (e.g., endorsement, emotional tone) may shape peer transmission processes.

Guided by this perspective, we identified an online community using three criteria: predominantly student-driven participation with little to no adult or bot or spam activity; high activity and diverse threads to support robust linguistic analyses; and a focus on schooling-related experiences, not general lifestyle or pop culture chatter. We identified r/SGExams as meeting these criteria. SGExams is Singapore's largest youth-oriented education forum, where students discuss academic subjects, examinations, study strategies, transitions, and peer issues. Its shared national context enhances the likelihood that expressions of curiosity are recognized and taken up by peers, making it well-suited for examining social transmission in authentic digital learning environments.

1.4 Current study

The current study investigated the extent of social transmission of curiosity in online educational discussions. To the extent that social transmission exists, we further asked about the nature of its transmission in terms of specificity and features that mediate these transmission effects. To this end, we analyzed our newly curated, large-scale dataset from an education-related Reddit community, SGExams. Curiosity was operationalized as question-posing using a new 2×2 taxonomy, crossing open/closed and possibility/non-possibility question forms. We analyzed transmission using generalized linear models and quantified mediating pathways using Monte Carlo-based counterfactual contrasts with ten cognitive and socio-affective discussion features modeled.

2. METHOD

2.1 Dataset construction and validation

Institutional Review Board (IRB) approval for retrieving and analyzing publicly-available deidentified data with a waiver of consent was obtained prior to the start of research. We built a custom data collection pipeline using Python Reddit API (PRAW v7) to retrieve posts and comments from SGExams. The dataset was compiled through an iterative, query-based procedure. This iteration was necessary as there are constraints in returns from a single API query. An initial word set (e.g., "exam," "teacher," common function words) was used to generate automated queries and returns. Unique terms were then incorporated to expand subsequent queries and returns. Retrieval continued until saturation, defined as no new returned posts or comments from additional queries (as identified by post/comment ID). The final dataset comprised 38,920 posts and 666,978 comments from January 2019 to October 2023, including metadata (timestamps, identifiers, flairs, etc.). For this paper, we applied two-step preprocessing based on post flairs (topic labels assigned to a discussion thread). Flairs with fewer than 4,000 comments or activity concentrated within a few months were excluded, retaining 12 flairs grouped into five broader topic categories. We also reconstructed the discussion hierarchy by pairing parent posts/comments with their child replies. Note that "parent-child" here refers to the discussion hierarchy for ease of communication, and not familial relationship. Because users generally do not reply to themselves, these parent-child links largely reflect between-user interactions.

To assess completeness, we conducted two validation procedures. First, we restricted automated queries to a one-month window and compared retrieved counts with manual tallies of posts and comments directly on SGExams subreddit website. Second, we cross-validated our dataset with a third-party aggregator of Reddit statistics (https://subredditstats.com/). To verify that contributors were adolescent students, we manually reviewed 200 highly active users (≥10 posts/comments). For each, up to 50 posts and comments were examined for explicit age disclosures (e.g., "I'm 16") and contextual indicators (e.g., references to secondary school levels, examinations, or post-secondary pathways). These checks assessed the dataset's coverage and demographic relevance to the target population.

2.2 Curiosity measures

Curiosity was operationalized as question-posing, aligned with past work on indicators of curiosity [7, 13]. Because questions typically start with question words, we used a rule-based classification at the sentence level. Table 1 presents the full categorization of question types based on the rules and their implied intent and stance. Each sentence was assigned to one and only one category based on the rules. Individual comments were often composed of multiple sentences and thus could contain more than one type of question. We performed a validation of our automated classification by manually labelling 1,807 randomly selected sentences.

2.3 Discussion mediators

We identified and engineered 10 literature-informed mediators capturing shared meaning-making and affective exchange in Reddit discussions. Cognitive mediators indexed epistemic alignment

between parent and child comments (e.g., lexical overlap, conceptual similarity, content uptake), whereas socio-affective mediators reflected social valuation, social referencing, and emotional alignment. Together, they operationalized potential mechanisms for the transmission of curiosity. The mediators were engineered using natural language processing, unsupervised learning as well as a hybrid lexical-semantic mining process that we developed. First, we started with a small dictionary of lexicons (e.g., "you're right,") and embedded them along with the full corpus' n-grams (up to 5) using a pretrained sentence transformer (all-MiniLM-L6-v2). An iterative algorithm identified semantically close and frequent n-grams, followed by manual screening for a final lexical list. This hybrid lexical-semantic mining thus incorporates both lexical, semantic information, and contextual information. This approach contrasts with more standard methods, such as LIWC which typically lacks incorporation of context and is not grounded in actual use frequencies. This method was applied to two mediators of agreement and social referencing. This automated mining was then validated against 1,000 human-labeled sentences. See Table 2 for a detailed exposition of the mediators, measurements, and sources.

Table 1. Question types: description, rule, and examples

Type	Implied intent/stance	Sentence starters	Examples
O-NP: Open, Non-possibility questions	Factual clarification; descriptive or explanatory intent; assumption of a knowable answer	('who', 'when', 'what', 'where', 'how', 'why') AND (NOT ('can', 'may', 'might', 'could', 'would', 'if', 'will'))	"what is the DAE process like" "where is my monohybrid dihybrid epistasis"
O-P: Open, possibility questions	Exploratory reasoning; hypothetical thinking; acknowledgment of multiple possible outcomes	('who', 'when', 'what', 'where', 'how', 'why') AND ('can', 'may', 'might', 'could', 'would', 'if', 'will')	"how might we interpret the data here" "how can i explain and link this to evaluation"
C-NP: Closed, non-possibility questions	Verification, or confirmation; primary expectation of a yes/no answer; settled knowledge assumption	'must', 'should', 'do', 'is', 'are', 'does', 'did', 'have', 'has'	"Is the form for your course only?" "should i go back to sec 2 algebra"
C-P: Closed, possibility questions	Feasibility checking; bounded outcomes	'can', 'may', 'might', 'could', 'would', 'will'	"could it be such that the seats are all full and some are left out" "can it explain your action"

Note. 'if' was not included as sentence starter in the possibility-closed category as we found that sentences starting with 'if' were almost all non-questions.

Table 2. Cognitive and socio-affective discussion mediators to assess pathways for transmission effect

	Description	Measurement	Source
Cognitive			
Target lexicon mimicry	Extent of target lexicon similarity, capturing specific surface-level interactional alignment	Proportion of parent target lexicons in children's target lexicons. Target lexicons refer to the list of words used to classify question types (Table 1)	Combined from parent and child comments
General mimicry	Extent of overall lexicon similarity, indicating general surface-level interactional alignment	Jaccard similarity of content words (i.e., excluding stop words)	Combined from parent and child comments
Semantic similarity	Level of conceptual alignment beyond specific word use, indicating shared meaning and focus	Cosine distance between parent and child comments in the embedding space of a pre-trained sentence transformer model (all-MiniLM-L6-v2, 384 dimensions)	Combined from parent and child comments
Local referencing	Degree of uptake of specific content, reflecting focused engagement	Counts of '>' in children. '>' is the community markdown norm for replying to specific statements/sentences made by the parent comment	Child comments
Agreement	Extent of public concurrence or endorsement, signaling public alignment	Counts of any of the following lexicons as mined by our hybrid lexical-semantic approach: 'me too', 'sameeee','i agree','you're right', 'ur right', 'you right', 'you make sense', 'u make sense'	Child comments
Socio-affective			
Popularity	Level of community endorsement, reflecting a comment's perceived importance and value	Number of upvotes; similar to likes on other social media platforms	Parent comments
Social referencing	Extent of relational references, signaling interpersonal links	Counts of any of the following lexicons as mined by our hybrid lexical-semantic approach: 'you say that', 'u mentioned', 'u say', 'what you say', 'you mentioned', 'you explain', 'youve mentioned', 'saying you', 'you mention'	Child comments
Sentiment - Parent	Affective valence, capturing overall emotional tone	Sentiment analysis using a transformer model fine-tuned for social media sentiment classification into three classes [17]: positive, negative, neutral	Parent comments

	Description	Measurement	Source
Sentiment - Child	Affective valence, capturing overall emotional tone	Same as Sentiment - Parent but for child comments	Child comments
Sentiment mimicry	Degree of affective valence matching, indicating emotional alignment	Whether the parent and child sentiments match	Combined from parent and child comments

2.4 Quantitative modeling

We first fitted generalized linear models (GLMs), specifically negative binomial regressions. Alternatives such as linear models were not appropriate given the zero-bounded, count data with substantially larger variance than means. Each GLM model predicted one child question type count from all four parent question types. Thus, four separate GLM models were run as there were four question type outcomes. Wald tests compared regression coefficients to assess narrow versus broad transmission. To strengthen inference, we conducted 1,000 randomization tests within a discussion thread that preserved marginal count distributions while breaking parent-child links. This allowed us to evaluate whether observed effects exceeded chance while taking into account discussion threads and topics. We also fitted GLMs for non-examination topics to probe boundary conditions. A total of 40 Wald tests were performed. We used Šidák multiple-testing correction, a less conservative procedure compared to Bonferron correction. As a robustness check, we also implemented logistic regression (binarizing outcomes). GLMs were implemented in MATLAB (2025b).

To examine transmission mechanisms, we applied Monte Carlo g-computation, a flexible and rigorous approach to mediation originating from causal inference framework [12, 21]. It estimates how an outcome would change under hypothetical (counterfactual) manipulations of predictors and mediators. Intuitively, the method uses fitted models to simulate what would happen if the parent comment had different levels of a predictor, while allowing mediators to respond accordingly.

For each parent predictor-child outcome pair, we fitted a negative binomial model for the outcome and separate models for ten candidate mediators (Table 2), all included simultaneously in a parallel mediation framework. Let A denote the parent predictor, M the vector of mediators, and Y the child outcome. Using 1,000 Monte Carlo draws from the estimated parameter distributions, we simulated counterfactual expectations under contrasting predictor levels a_1 and a_0.

Effects were decomposed into indirect and direct components using the potential outcomes framework. The indirect effect (IE) is defined as:

$$IE = \mathbb{E}[Y_{a,M(a_1)}] - \mathbb{E}[Y_{a,M(a_0)}],$$

which captures the change in the outcome due to changes in mediators induced by the predictor, holding the predictor fixed. The direct effect (DE) is defined as:

$$DE = \mathbb{E}[Y_{a_1,M(a_0)}] - \mathbb{E}[Y_{a_0,M(a_0)}],$$

which captures the change in the outcome due to the predictor, holding mediators fixed at levels corresponding to a_0. The total effect satisfies:

$$TE = IE + DE = \mathbb{E}[Y_{a_1}] - \mathbb{E}[Y_{a_0}].$$

Mediator-specific indirect effects were evaluated using 95% confidence intervals, with the proportion mediated computed as $IE/(IE + DE)$. Given the observational nature of the data, these effects are interpreted descriptively rather than causally as key assumptions such as temporal ordering and sequential ignorability (e.g., no unmeasured confounders) are not fully satisfied. Analyses were conducted in R (MASS and related packages).

3. RESULTS

3.1 SGExams: Descriptive statistics and validation

Table 3 presents comment distributions across consolidated SGExams topics. Original post flairs were grouped based on shared themes, educational stages, and temporal trends into five categories: Exam Preparation, Exam Outcomes, Pre-university, University, and Others. Exam Preparation includes study strategies, content questions, and challenges surrounding high-stakes national examinations held annually. Exam Outcomes centers on exam results and admissions. Pre-university covers broader secondary and post-secondary experiences beyond exams (e.g., relationships, school activities, internships). University focuses on college admissions and courses. The heterogeneous "Others" category (e.g., jobs, scholarships, rants) was excluded from further analysis. Our primary analyses focused on Exam Preparation, which constituted the majority of activity and was theoretically most conducive to transmission effects due to its high-stakes context; results for the other topics are reported in Appendix Table 1.

We conducted extensive validation before analysis. Retrieval completeness was assessed in two ways: comparison with manual counts over a one-month window (99.8% retrieval) and cross-checking with third-party statistics from https://subredditstats.com/ (97.8%). Although third-party methodologies are not fully transparent, converging evidence suggests near-complete retrieval, lending confidence to complete conversational hierarchy.

Demographic validation of 200 randomly sampled users showed that 174 provided age-indicative statements; of these, 93.7% appeared to be adolescents broadly defined as students between secondary school and college. Finally, automated question classification was validated against 1,804 human-labeled sentences (κ = 0.97 for double-coded subset), yielding a weighted F1 of 0.90. Together, these extensive validation procedures support the dataset's completeness and validity. The code and dataset are publicly available at our institutional data repository (*https://doi.org/10.25340/R4/SYASFR*). We have removed Reddit usernames as the dataset is made up of discussions by minors in order to afford some level of privacy. Linked data is available upon request.

3.2 Social transmission of curiosity

Four GLMs were estimated, each predicting the count of a specific child question type from the four parent question types. As hypothesized, we uncovered strong and reliable transmission effects of curiosity as measured by question-posing. Results for Exam Preparation consolidated topic specifically are presented in Table 4 (N = 136,010 filtered parent-child pair). A parent question type strongly predicted the same question type in the child comments. For example, a one unit increase in parent open, non-possibility question type was associated with a 205% increase in expected count of child open, non-possibility question type. Evidence for narrow transmission where the same parent question type

Table 3. Consolidated discussion topics, original post flairs, and their distribution

Consolidated topics	Original Flair Title	Count (% of Total)
Exam Preparation (50.3%)	Exam Megathread	119608 (20.9%)
	O Levels	108271 (19.0%)
	A Levels	47347 (8.3%)
	N Levels	12070 (2.1%)
Exam Outcomes (4.4%)	Results Megathread	24966 (4.4%)
Pre-University (17.1%)	Junior Colleges	48726 (8.5%)
	JC vs Poly	3878 (0.7%)
	Polytechnic	45126 (7.9%)
University (17.0%)	University	97016 (17.0%)
Others (11.2%)	Rant	54005 (9.5%)
	Jobs	4493 (0.8%)
	Scholarships	5585 (1.0%)

Note. Data shown is post-filtering (see Methods). "O Levels" and "N levels" are Singapore's national exam for secondary school while "A levels" is the national exam for high school. "Junior Colleges" or "JC" are senior high schools, while "Polytechnic" or "Poly" post-secondary vocational institutions.

preferentially predicted its own type in child comments was tested using pairwise Wald test. Each GLM, superscript [a] in Table 4 indicates whether the bolded parent question type similar to child question type predicted the child question type significantly better than the other parent question types. For example, parent O-NP predicted child O-NP significantly more strongly than other parent question types, as indicated by superscripts [a] for O-P, C-NP, C-P. A narrow transmission effect will produce superscripts for all other parent types. Narrow transmission was observed for open type questions, both non-possibility and possibility (though with one non-significant result) types. However, closed question types still statistically significantly predicted open question types, though with smaller effect sizes. Our randomization procedure identified 5.2% of GLMs coefficients that were statistically significant, in line with a Type 1 error of 5%, suggesting that our results cannot be explained simply by chance or thread clustering. In the Appendix, we performed the same GLM analyses for the remaining three consolidated topics that do not directly relate to the Exam Preparation topic. We found transmission effects though not as strongly and statistically reliably as Exam Preparation. Interestingly, Exam Outcome discussions were more likely to exhibit suppression effects, the opposite of transmission (Appendix Table 1), indicating that the nature and goals of discussions play important roles in social transmission. In summary, curiosity as measured by question-posing in student discussions strongly exhibits social transmission in high-stakes exam-oriented student discussions, though with more limited evidence for specificity in its transmission.

Table 4. GLM results predicting the outcome variable of child question type from parent question type

	Beta	SE	z	Corrected p	Relative ratio
O-NP (outcome variable)					
Intercept	-2.51	0.01	-176.95	<0.01	0.08
O-NP	1.11	0.04	31.13	<0.01	3.05
O-P[a]	0.19	0.15	1.31	0.99	1.21
C-NP[a]	0.36	0.04	9.61	<0.01	1.43
C-P[a]	0.27	0.06	4.28	<0.01	1.32
O-P (outcome variable)					
Intercept	-5.43	0.05	-119.77	<0.01	0.00
O-NP[a]	0.57	0.09	6.23	<0.01	1.77
O-P	1.22	0.29	4.21	<0.01	3.39
C-NP[a]	0.16	0.11	1.42	0.99	1.17
C-P	0.46	0.17	2.65	0.26	1.58
C-NP (outcome variable)					
Intercept	-2.64	0.01	-188.12	<0.01	0.07
O-NP[a]	0.84	0.03	24.36	<0.01	2.31
O-P	0.46	0.14	3.33	<0.01	1.58
C-NP	0.45	0.04	12.82	<0.01	1.57
C-P	0.35	0.06	5.65	<0.01	1.41
C-P (outcome variable)					
Intercept	-3.36	0.02	-179.49	<0.01	0.03
O-NP	0.57	0.04	13.12	<0.01	1.77
O-P[a]	-0.12	0.22	-0.54	0.99	0.89
C-NP[a]	0.36	0.05	7.69	<0.01	1.43
C-P	0.67	0.08	8.90	<0.01	1.95

Note. Four GLMs were used to predict each dependent variable of child question type from the four parent question types (+ intercept). For each GLM, Beta: GLM regression coefficient estimate (log scale). SE: standard error of the coefficient. z: Wald test statistic (Beta/SE). p: p-value for the Wald test. Relative ratio: exponentiated coefficient, exp(Beta), indicating multiplicative change in expected count of outcome variable for a one-unit increase in the predictor. The number minus 1 times 100% indicates the percentage change. For example, a unit increase in the count of parent O-NP was linked to a 205% increase in the expected count of child O-NP.
For each GLM, superscript [a] indicates whether the bolded parent question type predicts the same question type in the child comment significantly better than the other parent question types (based on pairwise Wald test). For example, in the GLM to predict O-NP, parent O-NP predicted child O-NP significantly more strongly than other parent question types, as indicated by superscript [a] for O-P, C-NP, C-P. A narrow transmission effect will produce superscripts for all other parent types. Such an effect was observed only for parent O-NP and O-P question types.
O-NP: open, non-possibility questions; O-P: open, possibility questions; C-NP: closed, non-possibility questions; C-P: closed, possibility questions. * Corrected p-values: *p < 0.05; ** p < 0.01; *** p < 0.001

3.3 Mediating pathways

To examine pathways mediating transmission, we applied a Monte Carlo simulation-based g-computation approach. Ten discussion features, five each in cognitive and socio-affective categories were tested as potential parallel mediators. Table 5 presents the results. Numbers are the percentage of total effects of the predictor on the outcome mediated by the respective mediator, i.e., indirect effects. The vast majority of indirect effects were statistically significant, suggesting reliable mediations that were, however, generally small on the order of ~5-15%. Bolded estimates represent the top 3 mediators for each of the question types. Popularity, as measured by upvotes, was frequently amongst the top mediators. This result indicates that the popularity of parent comment functions as a marker of social endorsement, increasing the likelihood that subsequent child replies reproduce curiosity. Agreement, as measured by public concurrence and endorsement, also played an important mediating role for all question types, suggesting follow-up comments were more likely to display curiosity when students were more aligned in their views and opinions.

Interestingly, target lexicon mimicry also significantly mediated the social transmission of curiosity, indicating that adolescent students are prone to question word re-use in their curiosity expressions. However, this question word re-use contrasted with negative mediation by general mimicry, which measures overall lexical re-use. This pattern of results highlights the selective epistemic uptake, and not merely broad language imitation. We also observed that the percentage of indirect effects tended to be quite similar for the different question types. Indeed, formal quantification revealed very high correlation in indirect effects estimates for all question types (Spearman's r = 0.79). This provides a plausible explanation for the general finding of broad curiosity transmission:

similar mediating mechanisms appear to operate across different question types, suggesting shared cognitive and socio-affective pathways rather than type-specific processes.

Table 5. Proportion of total effects of the parent question type on child question type mediated by 10 conversational features.

	O-NP ↓ Media-tor ↓ O-NP	O-P ↓ Media-tor ↓ O-P	C-NP ↓ Media-tor ↓ C-NP	C-P ↓ Media-tor ↓ C-P
Mediator: Cognitive				
Target lexicon mimicry	**7.27***	2.54	**5.64***	**12.24***
General mimicry	**-7.44***	-2.34	-1.50	**-6.06***
Semantic similarity	0.19*	-0.27	1.06*	-0.21
Local referencing	3.07*	2.40*	4.04*	2.98*
Agreement	6.05*	**6.05***	**6.97***	**6.00***
Mediator: Socio-affective				
Popularity	**15.20***	**11.32***	**10.05***	3.28*
Social referencing	0.79*	-1.96	0.27	0.92*
Sentiment - Parent	0.35*	**-3.25***	0.21*	1.09*
Sentiment - Child	1.64*	2.12	-1.38*	1.06*
Sentiment mimicry	-0.26	0.86	0.51	0.26

Note. Numbers are estimated percentages of the total effects of predictor on outcome mediated by the respective mediator. Bolded percentages are the top 3 mediators for each predictor-outcome relationship. * indicates statistically significant indirect effects ($p < 0.05$).
O-NP: open, non-possibility questions; O-P: open, possibility questions; C-NP: closed, non-possibility questions; C-P: closed, possibility questions.

4. DISCUSSION

Our study analyzed a new dataset of online educational discussions led by adolescent students. Leveraging a newly created large-scale and topic-rich nature of the dataset, we mined for intricate signals of curiosity transmission and its potential pathways using advanced regression models followed by more flexible Monte Carlo g-computation to further quantify mediation. We found strong social transmission of curiosity: parent question-posing robustly predicted child question-posing, in agreement with past studies suggesting social transmission of curiosity [2, 9]. There was limited evidence of narrow transmission, though broader cross-type effects emerged as strongly. Social transmission was especially strongest in exam discussions. Monte Carlo g-computation identified statistically reliable though modest mediating pathways. We found that popularity (upvotes) and agreement consistently mediated social transmission.

The finding that comment popularity plays one of the most important roles in socially transmitting curiosity is supported by previous findings. Participants indicated greater curiosity about the answers to scientific questions when the questions were presented with experimentally manipulated high vs. a low number of up-votes [6], highlighting the importance of social cues in promoting curiosity. Our study further extends this finding by demonstrating that popularity not only heightens individual curiosity toward content, but also shapes subsequent behavioral expression of curiosity in peer interaction. Specifically, highly upvoted parent questions were more likely to elicit follow-up questions from others, indicating that social endorsement functions as a diffusion mechanism of question-posing. Cognitive alignment, as operationalized by our agreement conversational feature, is also an important mediator of social transmission. Students were more likely to be curious when they agreed with the stance or perspective expressed in the prior comment. One possible explanation is that cognitive alignment creates a psychologically safe and supportive space in which extending the discussion through further questions becomes more likely, thereby facilitating the social propagation of curiosity.

We also found a dissociation between question word mimicry and general lexical mimicry, in which the former increases, but the latter decreases, curiosity propagation. This pattern can be interpreted through a social cognitive lens. Social cognitive theory posits that observational learning is selective: individuals attend to, encode, and reproduce behaviors perceived as meaningful, functional, or socially valued, not merely any behavior. The positive mediation by target lexicon mimicry suggests that adolescents selectively model epistemically relevant features (e.g., interrogative structures signaling curiosity), rather than broadly imitating surface language features. An experimental study lends support to this idea: children and adults re-use or novelly re-combine previously exposed questions, especially when they are informative, likely in the service of efficient inquiry and effective learning [15]. Our work also links to prior work on linguistic style matching in discourse analysis [8, 19], though our results provide more nuances, such as what linguistic aspects are being matched by adolescent students.

Our study extends past online discussion analyses in educational data mining/learning analytics. These studies have fruitfully applied computational linguistics methods with a focus on better understanding and predicting course participation and performance [e.g., 25]. We extend these studies to focus more on social transmission, particularly its mediating mechanisms, applying it to curiosity expressions by way of questioning.

Our study makes further contributions to research by introducing a scalable, multidimensional taxonomy of question-posing and applying it to a large, naturalistic dataset. Existing taxonomies often dichotomize questions into lower- versus higher-order types or rely on domain-specific distinctions (e.g., causal vs. descriptive in science), which can be overly reductive or limited in generalizability or scalability. By crossing openness (open vs. closed) with possibility thinking based on a previous framework [1], our extension captures variation in information-seeking intent while remaining adaptable across domains. Moreover, its reliance on identifiable linguistic markers enables highly reliable automated classification at scale. Coupled with a large corpus of peer-driven discussions that we have curated and continue to build on, this approach advances methodological tools for studying many aspects of educational discussions, including curiosity, as they unfold dynamically in authentic digital environments. While discussions in the context of formal settings (group work in a classroom or online course discussions) are relatively well studied, the dynamics of informal, peer-driven learning communities remain underexplored.

Our study has implications for educators as discussion facilitators and for designers of social learning platforms, though with important caveats. For educators, the findings suggest that curiosity can be socially amplified through visible endorsement and constructive alignment. Publicly recognizing thoughtful questions and modeling how to extend peers' inquiries can help cultivate inquiry-oriented norms [2]. However, overemphasis on popularity could privilege confident or dominant students; highlighting alignment might limit epistemic diversity. Educators, therefore, need to balance public reinforcement with inclusive facilitation strategies that invite diverse voices and stances. For platform designers, features such as upvotes, threading, and content highlighting can shape epistemic behavior by signaling what is valued. Yet, simple popularity metrics may also distort attention toward socially appealing rather than substantively rich questioning. Designing

systems that surface high-quality questions, such as via rotating visibility or algorithmic weighting, may better support equitable and sustained discussions.

We acknowledge limitations in the study. First, while our dataset is grounded in general educational discussions (unlike other general adolescent-based Reddit communities which can be dominated by pop culture and general lifestyle), it is nonetheless limited to one particular national educational context. Second, our modeling of mediation based on g-computation which originates from a causal inference framework. However, failing to meet strict causal assumptions such as sequential ignobility (e.g., no unmeasured confounding) and temporal ordering limits strong causal statements. For instance, due to the limitations of the Reddit API, upvote counts were returned as a single total with no temporal information. Another limitation is that the data has a hierarchical and networked structure. As such, observations are not fully independent, and standard errors from our GLMs may be underestimated. While our analyses partially controlled for discussion context by analyzing consolidated topic categories separately and performing within-thread randomization tests, we did not explicitly model all forms of clustering such as users and higher-order sequences (e.g., subheads within threads) operating at different scales [5, 14].

Considering these limitations, future studies can be extended in several ways. One interesting question is whether social networks play a role. While Reddit discussions are largely anonymous, repeated interactions create recognizable usernames and emergent micro-communities. An important next step is to examine whether curiosity transmission is influenced by network position or prior interaction history between users. Another promising direction is to investigate temporal dynamics: e.g., does repeated engagement with curious peers increase an individual's baseline propensity to ask questions over time, suggesting longer-term socialization effects beyond immediate momentary exchanges? We believe addressing these questions can illuminate fine-grained processes of how students learn digitally socially beyond the classroom.

5. CONCLUSION

This study demonstrates that curiosity, operationalized as volitional question-posing, is not merely an individual disposition but a socially transmitted behavior in peer-driven online discussions. Using large-scale data and computational modeling, we show that questioning propagates across interactions, with both broad and selective patterns shaped by cognitive alignment and social endorsement. By framing curiosity at the behavioral level, our findings highlight how learning-related inquiry emerges and spreads in authentic digital collaborative environments, offering insights for designing educational contexts that cultivate sustained, self- and peer-driven questioning.

ABSTRACT
Learner disengagement has been widely studied and modeled in math learning environments to enable timely supports and promote engagement. Recent advances in multimodal large language models (MLLMs) offer new opportunities for building such detectors. This study investigates the potential of an MLLM-based approach to detect disengagement from the task goal (DTG) in screen-recording videos of students solving math problems in CueThink. DTG is operationalized as actions unrelated to the intended learning task. We develop and validate a DTG detector using LLaVA-Video-7B-Qwen2(Large Language and Vision Assistant) using various prompting strategies, and analyze themes across the few model errors. We also examine associations between DTG behavior and learning gains, as well as students' math beliefs, anxiety, and metacognition. Results indicate that the model, using role assignment and chain-of-thought prompting, identifies DTG behavior with good performance ($\kappa = 0.71$, precision = 77.6%, recall = 76.4%). Performance limitations that emerged related to low-fidelity data, limited contextual knowledge, and following instructions. DTG behavior was marginally negatively correlated with normalized learning gains later in the academic year (winter to spring), but not during the earlier fall-to-winter period. There were no significant correlations to beliefs or anxiety.

Multimodal LLM, LLaVA, disengagement, math, problem-solving, detector, video-analysis.

1. INTRODUCTION
The field of Educational Data Mining (EDM) has long-standing interest in various types of disengagement within and across learning platforms [34, 21]. Student disengagement is a multifaceted meta-construct [43] that includes behavioral (e.g. gaming the system), emotional (e.g. boredom), and cognitive components (e.g. mind wandering) [19]. Identifying and understanding student disengagement is important to efforts to reduce it [1], as engagement is a necessary condition for learning and a key indicator of long-term achievement and academic success [36, 39]. Students can only benefit from the virtual learning environments if they are engaged with the system [10]. Engagement also plays a role in students' academic resilience and the development of resources for coping adaptively with stressors, which in turn may affect the development of long-term academic mindsets [37].

Within online learning contexts, disengagement has been modeled using various Machine Learning (ML) models. Specific examples of disengaged behavior include DTG (Disengaged from Task-Goal) [22], gaming the system [5], off-task behavior [4], and mind wandering [32]. There has been increased interest in identifying the various ways students can deviate from expected patterns while using educational software, including not using features of the platform and failure to engage with content [21]. Detection of these behaviors has helped researchers better understand them, allowing researchers and teachers to develop interventions that can remediate them and reduce their negative impacts on user outcomes [2].

For this paper, we focus specifically on Disengagement from Task Goal (DTG). This behavior has been observed in online learning but given a variety of names in the published literature [22, 35, 8, 42]. Examples include students who, instead of plotting points from a mathematical function in a learning platform for high school mathematics, plotted a smiley face [42]. In other learning systems, learners have avoided diagnosing virtual patients and instead placed virtual unrelated objects on them [35], tinkered with science simulations in ways unrelated to the stated learning goals [8], or otherwise engaged in actions that appear to have no relationship to the intended learning task [42]. To date, the majority of studies of DTG have been in science learning environments [22, 35, 42], with very limited work in math contexts.

In the context of math problem solving, DTG may take several forms, including using math tools and text to draw silly drawings, making smiley faces when plotting points, creating repetitive designs and patterns, typing curse words instead of answers, or writing funny terms for friends. It is worth noting that DTG differs from off-task behavior as that is typically understood: off-task behavior typically involves disengaging completely from the learning task, whereas in DTG, the student is engaging with the task, but in a fashion unrelated to the learning task's design goals or incentive structure.

Disengagement detectors have often been built using classical machine learning (ML). However, ML-based models are time and resource-intensive, requiring extensive feature engineering and labeled datasets. With the advancements in generative AI and large

language and multimodal models, new opportunities have emerged for building detectors. Large language models like ChatGPT have shown potential in facilitating education research through supporting qualitative data analysis tasks such as coding transcripts and analyzing open-ended responses [45, 48, 30]. Recent advances in multimodal large language models (MLLMs) have extended these capabilities to process both visual and textual information [47]. MLLMs have demonstrated promising results in tasks such as image captioning, video understanding, and visual question answering [44, 48].

One potential application of MLLMs in educational research is facilitating qualitative video analysis, which has yielded important results about students' learning processes, but previously required time-intensive coding of behavioral patterns and interactions [16, 33]. Emerging educational research has explored Machine Learning classification to detect teaching and learning moves [18], but these efforts also relied on manually coded data for training. Early work with MLLMs in online learning has been promising [51], demonstrating their potential for streamlining this process by supporting video selection and behavior coding—tasks that traditionally require significant manual effort from researchers. To date, however, their use for modeling DTG has not yet been studied.

Accordingly, the focus of this paper is to build and validate a DTG detector based on the multimodal LLM, LLaVA (Large Language and Vision Assistant) [27], and to systematically analyze its errors. Additionally, we examine how DTG behavior correlates with learning gains and measures of math beliefs, anxiety, and metacognition in math problem-solving—constructs that research has shown are increasingly important for math learning [3, 13, 15].

2. METHODS

2.1 Learning Platform and Data Collected

CueThink (2022) is a digital learning application designed to enhance middle-school students' mathematics problem-solving skills by encouraging self-regulated learning (SRL) and supporting students in sharing their problem-solving processes. The platform asks students both to solve a mathematics problem and to create a shareable screencast video that presents their solution and demonstrates their reasoning. CueThink structures each problem into a Thinklet, which consists of four phases—Explore, Plan, Solve, and Review—that closely align with Winne and Hadwin's [41] SRL model. A full description of the CueThink phases is provided in Zhang et al. [49].

The study included 180 students in Grades 6–8 from suburban schools in the Southwestern United States who used CueThink during the 2021–2022 school year. Self-reported gender demographics were collected (66 boys, 98 girls, 1 non-binary, 3 chose not to report, and 12 had missing values). Across the year, students completed 746 Thinklets (4.09 Thinklets per student, on average). Pre- and post-test surveys were administered at the beginning and end of the school year; the survey scales are described in detail below (section 2.4).

This study primarily makes use of data from the Solve phase. During this phase, CueThink collects fine-grained interaction log and trace data capturing students' whiteboard actions, including position coordinates for each pen stroke (e.g., initiating a path and rendering it point-by-point). Students can use a variety of mathematical tools and objects on the whiteboard—such as number lines, protractors, tables, highlighters, and text/equation entry (Figure 1). These interaction traces can be rendered into a screen-recording that visualizes students' step-by-step work as they solve the problem. These videos were used both as inputs to the model and to establish ground truth labels (see section 2.2).

All data were collected and analyzed under a protocol approved by the University of Pennsylvania Institutional Review Board (IRB protocol number 856358). The LLaVA model was run locally on our lab server for analysis, so no data was transmitted to any external server, minimizing data privacy risks.

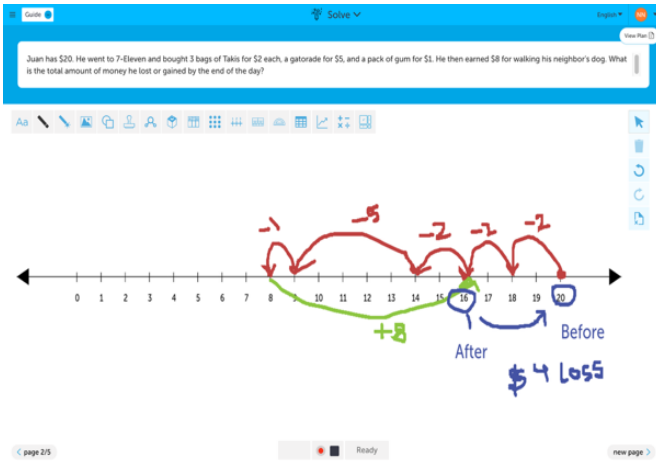

Figure 1. Solve Phase in CueThink

2.2 Operationalizing DTG

DTG (Disengaged from Task Goal) was operationalized as actions that have no relation to the intended learning task. The intended learning task here is to use system-internal tools to write and solve an equation on the digital whiteboard, and tools included a number line, table, protractor, ruler, or mathematical symbols. Each video was binary coded for DTG behavior by 2 researchers to establish the ground truth. Each researcher watched the full video, which showed all the students' actions in chronological order as they solved the math problem in the context of the learning environment, to then make a decision about whether DTG behavior was ever observed or not.

The operationalization was developed through an iterative process to ensure that the behaviors classified as DTG aligned with previous conceptualizations [22] and were salient in the dataset. Through this process, indicators of engagement (non-DGT behavior) were readily agreed upon, including using a number line to add or subtract or organizing given values in the problem statement into a table to solve the problem, or any written text or images drawn for finding a solution. Meanwhile, several specific criteria for DGT were identified, including: (1) text unrelated to given math problems, (2) usage of given math tools for purposes other than solving the math problem, and (3) other task-unrelated actions (silly drawings, smileys).

Some clarifications were made to the DGT criteria. For example, behaviors that might have indicated DTG were ignored if they occurred after the problem was completed. As such, if the video included a student who finished solving the problem on the whiteboard with a solution before creating an unrelated drawing, the video was not labeled as DTG. If the video is blank and no actions take place on the whiteboard, it is also not treated as DTG because there was no action.

Using this operationalization, two coders first independently coded 120 videos from a separate dataset from another year on the same learning system to establish interrater reliability ($\kappa = 0.79$). Once consensus was reached, the coders proceeded to code a total of 746 videos from 180 students. These coded videos constituted our "ground truth" that was used to compare against model labels to validate the model's performance. Of these 746 videos, 546 videos from 129 students were designated as the development set and used for iterative prompt refinement and evaluating strategies, while the remaining 200 videos from 51 students (none of whom appeared in the development set) served as a held-out test set for evaluating the final model's performance and further analysis.

2.3 LLaVA as a DTG detector

2.3.1 LLaVA Model Details

We used LLaVA-Video-7B-Qwen2 [50], a state-of-the-art video MLLM was selected because it reflects recent technological advances in video MLLMs, is open source, and has demonstrated suitable performance on video understanding benchmarks [20,50] and in educational applications [51]. We used the pre-trained model with temperature set to 0 to ensure reproducibility. We did not fine-tune the model because our aim was to assess the potential of existing pre-trained models for detecting disengagement behaviors, and fine-tuning requires substantial computational resources and large annotated datasets.

2.3.2 Video Analysis and Script Setup

To process the video data, we selected sampling and segmentation settings that balance temporal coverage and processing capacity. Each video was first decomposed into individual frames. These frames, together with the text prompts—were tokenized as inputs to the model. Because the MLLM has a fixed context window that limits the total number of tokens it can process at once, analyzing longer videos involves a trade-off between the number of tokens allocated per frame (increasing visual detail) and the total number of frames included (increasing temporal coverage).

Each video was segmented into 10-second clips and sampled at three frames per clip. This conservative choice was derived empirically by testing multiple segmentation lengths (i.e., 10, 5, and 1-second clips) and sampling values (3 vs. 5 frames per clip), in order to capture sufficient student actions and visual context to support DTG coding while remaining within token limits. Different segment lengths and sampling rates showed no meaningful differences in output quality, and therefore, we adopted a 10-second segmentation with three frames per clip (approximately one frame every 3.3 seconds, or ~0.3 fps) to maintain computational efficiency. All clips were then processed through LLaVA using the refined prompt. To obtain a single video-level prediction per student, clip-level predictions were aggregated using an inclusive decision rule, such that, if DTG behavior was identified in one or more clips within a video, the student was labeled as exhibiting DTG behavior for that problem.

2.3.3 Prompting strategies

We employed an iterative approach to refine the text prompts given to LLaVA using the development set (546 videos), focusing on maximizing the accuracy of labeling for DTG behavior. Once prompt development was complete, we evaluated the final prompt configuration on a held-out test set of 200 videos to assess the model's performance on unseen data. Given that LLaVA—like other generative models—is known to be sensitive to prompt framing and task specification [40, 29], we tested several prompting strategies, including (1) a baseline prompt, (2) a role-assignment strategy (which assigns a specific role or perspective to the model in order to facilitate a more contextualized interpretation e.g., Liu et al. [29]), (3) a chain-of-thought strategy (which facilitates step-by-step reasoning processes), (4) a combination of both approaches. These prompting strategies were selected based on prior work showing that prompting choice can affect multimodal LLM output. Chain-of-thought prompting has been shown to improve visual reasoning in multimodal LLMs, including LLaVA [48], while role-assignment has produced mixed results across settings [29]. We tested both techniques and their combination to identify the configuration best suited to DTG behavior labeling for our data. We also tested variations by changing key instructional verbs (e.g., "analyze" vs. "examine") while maintaining the role assignment component. Additionally, we provided contextual knowledge about math problem-solving in the prompt to help the model identify regular math-solving actions (task-related actions), such as strikethroughs to numbers and text that indicate problem-solving processes.

Baseline Prompt. The baseline prompt was as follows:

"Assign a binary code for DTG (disengagement from task goal) behavior defined as 'actions that have no relation to the math problem."

Role assignment and chain-of-thought strategy. The baseline combined-approach prompt was as follows:

"You are a [role assignment: qualitative coding expert] and your task is to [analyze/examine] and assign a binary coding for the construct of DTG (disengagement from task goal), which is defined as 'actions that have no relation to the math problem'. The videos show the whiteboard with student actions. The intended learning task for students was to solve math problems using the given tools (like a number line, table, protractor, or ruler, and other mathematical symbols). [chain-of-thought reasoning: insert step-by-step rules for operationalization criteria]."

Throughout this iterative process, we maintained concise prompts to optimize token allocation, as longer prompts can lead to attention dilution [23, 28] and degrade model performance even before reaching technical token limits [26].

2.3.4 Validation of LLaVA's DTG labels

During the prompt-refinement process, prompts given to LLaVA used a development set (546 videos), focusing on maximizing the performance of the model for correctly labeling DTG behavior. Once prompt development was complete, we evaluated the final prompt configuration on a held-out test set of 200 videos to assess the model's performance on unseen data across three metrics—kappa, precision, and recall.

2.3.5 Error Analysis

After finalizing the prompt, the test dataset was sent to the model for binary coding the videos for DTG behavior. For any clips where the MLLM label contradicted the human ground-truth label, further analyses were conducted. Namely, the 1st and 3rd authors re-watched the associated videos and analyzed these clips to identify potential causes of disagreement and possible instances of model hallucinations. We then conducted a thematic analysis [7] to distill recurring patterns across these errors, iteratively grouping these observations into broader categories.

2.4 External Survey Measures

Validated external measures were used to assess students' content knowledge [14], math anxiety [9], metacognitive awareness [38], and beliefs on problem-solving [25]. Each of these measures was

used first as a pre-test and then as a post-test. Once the pre-test was complete, students were provided with access to the learning platform. Their interaction with the platform was integrated into their regular classroom instruction, with their teacher assigning problems for them to complete.

Content Knowledge. Partnering districts administered i-Ready diagnostic assessments [14] as a proxy for mathematics content knowledge. The i-Ready [14] instrument is an adaptive assessment tool used to identify math topics students are struggling with; it examines students' understanding of mathematical sub-domains, including numbers and operations, algebra, geometry, and measurement. This assessment was administered three times, once each at the beginning (September), middle (December to January), and end (May) of the academic year.

Normalized learning gains [31] were calculated for those periods for the i-Ready tests from Fall to Winter; and Winter to Spring as NormLG_F-W and Norm_LG_W-S, respectively:

$$\text{NormLG} = \begin{cases} (\text{post} - \text{pre})/(\text{max} - \text{pre}) & \text{if post} \geq \text{pre} \\ (\text{post} - \text{pre})/\text{pre} & \text{if post} < \text{pre} \end{cases}$$

The normalized gains for two semesters were used for correlation analysis, and not the raw i-Ready scores.

The Junior Metacognitive Awareness Inventory (JrMAI) is a measure of metacognitive and cognitive strategies applied by learners [38] that was developed for students in grades 6 through 12. The current study uses a 9-item abbreviated version of the JrMAI that was validated with students in grades 6 -8 [24]. The measure includes 5 items identified as regulation of cognition and 4 items identified as knowledge of cognition.

The modified Abbreviated Math Anxiety Scale (mAMAS; [9]) uses a two-factor structure, which results in two subscales learning math anxiety (Learning subscale), and math evaluation anxiety (Evaluation subscale) [9]. The scale has shown good internal consistency, with an overall Cronbach's α of 0.85, a Cronbach's α of 0.77 for the Learning subscale and a Cronbach's α of 0.79 for the Evaluation subscale [9, 11]. The scale was developed for math learners between 8 and 13 years old (i.e., overlapping our research sample) and includes a 9-item self-report of math anxiety that are averaged to produce one final scale for analysis. The mAMAS was slightly modified to change adapted words to American English (e.g., "maths" to "math").

The Indiana Mathematics Belief Scales (IMBS; [25]) prompts students regarding their beliefs about mathematics and mathematical problem-solving over a 36-item survey. The measure is divided into six subscales. In this work, we used 2 of the 6 subscales (1 and 6). Specifically, we administered shortened versions of three subscales, which measure (a) student beliefs that they can solve time-consuming math problems (5 items), and (b) student beliefs on useful of math in their real lives, respectively (3 items). The shortened versions were validated using middle school students.

2.4.1 Analysis

In addition to the analysis of LLaVA's performance to accurately label DTG behaviors, we also examined the association between DTG labels and the external measures in this study. For analysis, first we aggregated DTG behavior at the student level by averaging DTG across each student's Thinklets. Then, for calculating correlations with survey measures, we used Spearman rank correlation because the variables were non-normally distributed. Afterwards, we applied Benjamini–Hochberg post-hoc corrections to control the false discovery rate for multiple comparisons [6].

3. RESULTS

3.1 Performance across prompts

Several metrics were used for evaluation including Cohen's kappa (κ), which was calculated for how well specific prompts produced outputs in agreement with human labels. Precision indicated the proportion of positive predictions that were correct. Recall measured the proportion of actual positive instances that the model successfully identified.

Table 1 reports the 3 metrics across the baseline prompt and prompt variations that introduced role assignment, chain-of-thought–inspired prompting, and their combination, evaluated under two phrasings ("analyze and assign" vs. "examine and assign").

Table 1. Kappa (κ), precision, and recall across prompts

Prompt Strategy	Analyze and Assign			Examine and Assign		
	κ	Prec.	Recall	κ	Prec.	Recall
Baseline	0.40	50.4%	59.0%	0.34	48.7%	59.2%
Role-assignment only	0.68	75.0%	78.3%	0.57	62.7%	75.5%
CoT only	0.60	66.7%	74.5%	0.53	59.2%	71.0%
Role-assignment + CoT	0.71	77.6%	76.4%	0.65	71.4%	75.3%

Across different prompting strategies, the 'role-assignment and chain-of-thought (CoT)' prompt with 'analyze and assign' achieved the highest kappa (κ = 0.71) and precision (77.6%), though role-assignment only had marginally higher recall (78.3% vs. 76.4%). This was followed by 'role-assignment only' with 'analyze and assign' (κ = 0.68, precision = 75%, and recall = 78.3%). Overall, 'analyze and assign' had higher values across all metrics and prompting strategies in comparison to 'examine and assign'. The baseline prompt, without any context or role, had the lowest scores for both 'analyze and assign' (κ = 0.40, precision = 50.4%, recall = 59%) and 'examine and assign' (κ = 0.34, precision = 48.7%, recall = 59.2%). We selected 'role-assignment and CoT' with 'analyze and assign' as the final prompting strategy due to higher metrics overall, and also balanced precision and recall, This prompt was used by the model to code the test set that was used for further analyses.

3.2 DTG Rates

The descriptive statistics of Disengaged-from-Task-Goal (DTG) behavior coded by the LLaVA model show that, across all Thinklets (N = 746), 79 were coded as DTG (10.59%), consistent with prior reports of DTG rates (e.g., Gobert et al., 2015; Sabourin et al., 2013). At the student level (N = 180), 67 students (37.22%) exhibited DTG behavior at least once across Thinklets. For each student, the DTG average was computed as the proportion of that student's Thinklets coded as DTG (DTG-coded Thinklets ÷ total Thinklets), with a score ranging from 0 (no DTG behavior) to 1 (DTG behavior on all Thinklets completed by that student). By self-identified gender, 32 of 66 boys (48.5%) and 33 of 98 girls (33.7%) exhibited DTG behavior. One non-binary student showed no DTG; among the three students who chose not to report gender, one showed DTG. A small number of students had missing gender values and were excluded from gender-specific percentages.

3.3 Error Analysis

The model showed good performance, comparable to or better than previous ML-based approaches for DTG behavior [22, 35].

However, to understand the few cases where it failed and enable future improvements, we conducted an analysis of cases incorrectly labeled as DTG behavior by the LLaVA model. We identified distinctive themes that can be categorized as follows:

3.3.1 Visual processing difficulties (low-fidelity data)

The LLaVA model exhibited systematic mislabeling stemming from low-fidelity visual interpretation challenges. Small-scale features posed particular difficulties: miniature smiley faces were incorrectly flagged as DTG when they were constructed from text characters like semicolons and parentheses (e.g., ";)" or ":)"), and small font sizes substantially increased OCR (optical character recognition) error rates. When handwritten objects appeared visually similar to numeric values, the model struggled to distinguish between task-relevant content and off-task elements—a differentiation that proved especially challenging given the handwritten nature of student work.

The model demonstrated poor recognition of cursive script and unclear handwriting. Pen scratches used by students to correct or cross out content were systematically mislabeled as DTG behaviors, as were unclear handwriting, numerical scribbles, and ambiguous pen-drawn elements that human annotators identified as legitimate task-related work. Additionally, when small objects overlaid background elements, human raters easily recognized the highlighted foreground from its color contrast, but the model often did not, indicating limitations in using color and spatial reasoning for labeling by the model. LLaVA connects a vision encoder (e.g., CLIP ViT) to a language model via visual instruction tuning [27], and not a conventional OCR pipeline, which might explain its sensitivity to tiny/cursive text and overlaps.

3.3.2 Lack of contextual knowledge

The model demonstrated insufficient understanding of mathematical tools, their appropriate usage contexts, and math problem-solving conventions. It mislabeled legitimate mathematical notation and work-in-progress indicators as DTG. For instance, tally marks, which human annotators recognized as counting tools based on their implicit contextual knowledge, were incorrectly flagged as disengagement. Similarly, incomplete solutions where students had drawn circles or shown intermediate steps without final answers were coded as DTG, whereas humans interpreted these as unfinished work rather than disengagement.

The model also struggled with distinguishing purposeful tool use from disjointed, unrelated behavior. Cases involving overlays of multiple mathematical objects (e.g., protractors, circles of different radii, rows of circles, colorful blocks, empty tables) were sometimes coded as 'not DTG' by the model when they clearly represented disengagement rather than actual problem-solving. Similarly, the rapid use of multiple mathematical tools to create unrelated imagery (e.g., multiple consecutive circles and lines forming an eye shape) was sometimes also difficult for LLaVA to recognize as DTG. Furthermore, the model did not interpret the written text correctly in the math problem-solving context. When students wrote text clearly unrelated to the problem, human annotators could read and infer the DTG behavior of the content, but LLaVA lacked this interpretive capability.

3.3.3 Instruction-following limitations

Consistent with previous findings [51], LLaVA model sometimes was unable to follow all of the instructions it was given, particularly in following conditional rules specified in the prompt. For example, it was unsuccessful at following instructions stating that activities that occurred after the student had completed the problem should not be classified as DTG.. Such errors are instructive about the limitations of LLaVA, which nonetheless achieved an overall model performance high enough to justify its use in aggregate correlational analyses.

3.4 Correlating DTG and Survey Measures

After applying the Benjamini–Hochberg post-hoc correction [6], none of the results of the Spearman correlations between students' disengagement from task goal (DTG) behavior and various outcome measures. However, marginally significant results (defined as $p < 2 \times$ adjusted α) were observed for one measure: normalized learning gains from winter to spring ($\rho = -0.278$, $p = 0.02$, adjusted $\alpha = 0.013$). In other words, students who more frequently engaged in DTG behavior demonstrated lower learning gains during this period. However, the relationship did not hold for normalized learning gains as calculated from fall to winter ($\rho = -0.155$, $p = 0.118$, adjusted $\alpha = 0.02$), suggesting that the negative effects of DTG may become more pronounced in the later part of the academic year.

The positive correlation between DTG behavior and post-test scores on the Indiana Mathematics Belief Scale (IMBS) subscale measuring beliefs about solving time-consuming math problem was not significant after post-hoc correction ($\rho = 0.157$, $p = 0.009$, bh-adjusted $\alpha = 0.004$), as the p-value was not below the critical (adjusted α) value. This correlation was also absent at pre-test ($\rho = -0.031$, $p = 0.687$, bh-adjusted $\alpha = 0.038$). No significant correlations were observed for the belief subscale on the usefulness of mathematics at either of the tests.

The negative correlation between DTG behavior and pre-test scores on the Math Anxiety Scale learning subscale was not significant after the Benjamini–Hochberg post-hoc correction ($\rho = -0.146$, $p = 0.018$, bh-adjusted $\alpha = 0.008$), as it did not meet the critical value criterion. This relationship was not significant at post-test ($\rho = -0.026$, $p = 0.736$, bh-adjusted $\alpha = 0.042$). The evaluation subscale of mathematics anxiety showed no significant correlations at either time point, which may reflect the fact that students were engaged in regular mathematics instruction rather than high-stakes testing contexts.

No other significant correlations were observed between DTG behavior and the metacognitive awareness scale.

4. DISCUSSION & CONCLUSION

4.1 Main Findings

This study demonstrates the potential of using LLaVA (Large Language and Vision Assistant), a multimodal large language model (MLLM) for automated detection of disengagement from task goal (DTG) behavior in screen recordings of virtual educational software. The pre-trained LLaVA model achieved acceptable performance ($\kappa = 0.71$, precision of 77.6%, and recall of 76.4%) in detecting DTG behavior during math problem-solving tasks. This shows that the model had high agreement with human raters while effectively minimizing both false positives and false negatives, and maintained balanced performance across the two metrics, suggesting robust and reliable detection capability across different types of DTG instances.

Rates of DTG labels by LLaVA model were consistent with prior reports of rates of this behavior across learning platform [22, 35]. Different prompting strategies were evaluated to improve the model performance, since the models are known to be sensitive to prompts. The results showed that framing the task to "analyze and

assign" and including assigning a role and chain-of-thought reasoning produced the highest kappa scores for coding DTG.

Analyzing the few error cases, the visual processing issues align with known weaknesses in vision-language models that rely on visual instruction tuning rather than dedicated OCR pipelines, particularly when processing low-resolution or visually ambiguous inputs [27]. Such challenges can be harder in educational settings where student-generated content is inherently messy, handwritten, and varies in quality. A lack of in-depth contextual knowledge of math, specifically understanding the tools and problem-solving processes required for particular tasks, represented another category with instances of incorrect DTG labels. A similar effect has been documented previously by Huang et al. [23], where they show that when multimodal LLMs lack sufficient contextual grounding, they can move toward speculative interpretation rather than evidence-based analysis. Lastly, the instruction-following limitations, including failures to apply conditional logic, are consistent with past findings [51], suggesting that sometimes gaps in sequential reasoning exist for the model.

While no correlations were statistically significant after the B&H correction, the marginally significant negative correlation between DTG behavior and normalized learning gains from winter to spring reflects an interesting relationship between DTG behavior and learning outcomes that warrants further investigation with larger samples. Notably, this association was absent in the fall-to-winter period, which may indicate that the cumulative effects of DTG behavior can become more harmful as the academic year progresses and mathematical content increases in complexity, consistent with prior research linking off-task behavior to reduced learning over time [12].

4.2 Future Work

This work has demonstrated the ability of MLLMs to considerably speed the labeling of DTG behaviors. Future research should investigate the individual differences and situational factors that lead students to engage in DTG behavior. For example, it is possible that students who engage in DTG are exhibiting a work avoidance goal orientation [17]. If researchers could distinguish between students who engage in DTG because they lack the necessary knowledge or skills and students who engage in DTG because the task is too easy, for example, we might be able to develop stronger scaffolding and adaptivity.

One approach to exploring this would be to examine DTG behavior using a broader range of survey metrics, including those that might be used for studies of students across learning domains (i.e., to determine if the same kinds of behaviors that emerge in a students' math classes also show up in science). However, additional qualitative data might also be informative. For example, now that there are functional DTG detectors for CueThink, it would be possible to use them to trigger classroom interviews, which allow researchers to approach, observe, and interview students at the moment a construct of interest occurs. In the context of DGTs, this could lead to a deeper understanding of this behavior and the needs of the students who exhibit it.

In addition to deeper investigations of DTG behaviors, future work should also explore ways to improve model performance and to validate it across different learning domains and student populations. These approaches should likely include:

Improving data size and quality: Researchers should provide high-fidelity data when using MLLMs for automated coding. Since large language models cannot reliably predict uncertainty or provide confidence intervals for their labeling [46], they cannot effectively mark boundary cases where human judgment would naturally acknowledge ambiguity.

Domain knowledge integration: The model would benefit from a lightweight domain ontology for common math tools and their typical usage patterns (e.g., protractor → angle labels; tally marks → counting). Additionally, implementing consistency checks to ensure tool presence co-occurs with task-relevant structure (labels, measurements, aligned marks), enhancing text understanding for semantic relevance to flag unrelated content as DTG, and training with negative examples showing decorative or purposeless tool use would improve contextual understanding.

Experimenting with fine-tuning: OCR capabilities can be enhanced through fine-tuning via visual instruction tuning specifically for handwritten mathematical content [27]. This targeted fine-tuning could address the model's current sensitivity to cursive text, small-scale features, and overlapping elements. However, this would require a much larger dataset, and is computationally expensive.

4.3 Conclusion

This study developed and validated a multimodal large language model (MLLM)–based detector for Disengagement from Task Goal (DTG) behavior using LLaVA (Large Language and Vision Assistant) on screen recordings of middle school students solving math problems on the CueThink platform. Among the prompting strategies evaluated, the combination of role assignment and chain-of-thought reasoning with an "analyze and assign" framing achieved the highest performance ($\kappa = 0.71$, precision = 77.6%, recall = 76.4%). These results suggest that an off-the-shelf, pretrained MLLM can detect DTG behavior in visual data with acceptable performance, without the extensive feature engineering and large annotated datasets traditionally required by classical machine learning approaches.

Analysis of the misclassified instances helped us identify key model limitations and inform areas for future improvement. DTG was negatively correlated with learning gains from winter to spring, with a marginally significant association, suggesting that the negative effects of DTG may become more apparent later in the academic year.

Overall, the ability to detect DTG in screen recordings of learners' interactions with a math platform opens new possibilities for analyzing behavior and delivering timely support in digital learning environments. This could help ensure that students engage meaningfully with assigned tasks and ultimately achieve better learning outcomes. As MLLMs continue to improve, they hold considerable potential to make large-scale educational video analysis more reliable and scalable.

5. ACKNOWLEDGMENTS

The authors would like to thank the CueThink team for their partnership and collaboration on this work. The authors also acknowledge Yiqiu Zhou and Maciej Pankiewicz for their support in setting up the model.

ABSTRACT

AAT-based programming practice often relies on log outcomes that obscure learners' underlying cognitive difficulties, behavioral workflows, and regulation dynamics. This study synchronizes submission logs, eye tracking, and wearable physiology to examine how these processes unfold during authentic AAT-based programming and how they differ by prior knowledge. Twenty-two university students completed a 35-minute session with four beginner Python questions while wearing a Pupil Core eye tracker and an EmbracePlus wristband. We coded attempt-level syntactic, conceptual, and strategic difficulties, annotated seven task-relevant behavioral states from screen–gaze recordings, and analyzed physiological signals across preparation and programming stages. Results showed that low prior-knowledge learners produced more syntactic and conceptual difficulty attempts, cycled more often between learning materials, feedback, and code revision, and showed larger reductions in physiological regulation during programming. These findings demonstrate how temporally aligned multimodal evidence can move AAT analytics beyond outcome tracking toward process-sensitive learner models that adapt support to cognitive difficulty, behavioral transition patterns, and regulation states.

Introductory programming, automated assessment tools, learning analytics, eye-tracking, physiological regulation

1. INTRODUCTION

Learning to program involves progressing from mastering language features, to forming domain concepts, and ultimately to solving novel problems [34, 28, 21]. In large programming courses, scaling such formative practice increasingly relies on automated assessment tools (AATs) embedded in learning management systems. AATs execute submissions against predefined test cases and return error messages, failing test indicators, and scores [22], that making practice frequent, measurable, and comparable across students.

Huiyong Li, and Boxuan Ma. Multimodal Learning Analytics for Programming: Cognitive Difficulties, Attention Dynamics, and Physiological Regulation. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) This fast feedback has enabled a growing body of computing education and educational data mining research on engagement, persistence, and performance in AAT-based settings [8]. However, the same observable trace can be produced by fundamentally different cognitive states: a student may repeatedly fail due to a minor syntax slip, a fragile misconception, or an unproductive strategy (e.g., trial-and-error), yet these processes can appear similar in logs. In this sense, log traces primarily capture what learners did and whether it worked, offering limited evidence about how and why those behaviors unfold. Complementary evidence streams point to this missing process layer. Prior work suggests that programming success and failure are associated with distinct visual attention strategies [35], and physiological sensing can index variations in cognitive and affective effort during code comprehension [7]. However, in AAT-based problem solving, explaining why superficially similar log traces arise often requires linking observable actions to learners' attention allocation and regulation dynamics at a fine temporal granularity. Multimodal learning analytics (MMLA) provides a methodological basis for synchronizing and triangulating these heterogeneous streams [27]. Yet such synchronized, fine-grained integration remains uncommon in authentic AAT task solving, where behavioral traces, attention dynamics, and regulation signals must be aligned to reveal process mechanisms rather than outcomes alone.

Despite the data richness of AAT-based programming learning, three gaps remain. First, prior work typically analyzes a single modality in isolation, limiting explanatory power because each stream is ambiguous on its own [36, 18]. Second, process-level differentiation of learners remains underspecified: we still lack sequence-sensitive characterizations of behavioral states, which cognitive difficulties emerge and how they co-occur with strategy-relevant behaviors across problem-solving episodes [16, 14]. Third, physiological regulation dynamics are rarely examined alongside fine-grained programming behaviors in authentic AAT task solving, leaving unclear whether and how physiological regulation signals difficulty, supports recovery, or differentiates effective versus ineffective strategy shifts.

To address these gaps, we integrate log-based cognitive difficulty coding, eye-tracking attention dynamics, and physiological regulation measures to characterize programming processes and contrast high and low prior-knowledge learners. We address the following research questions:

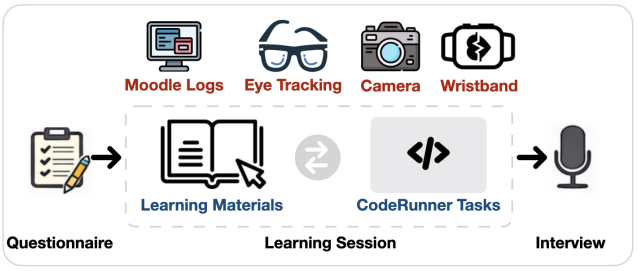

Figure 1: Overview of the study procedure.

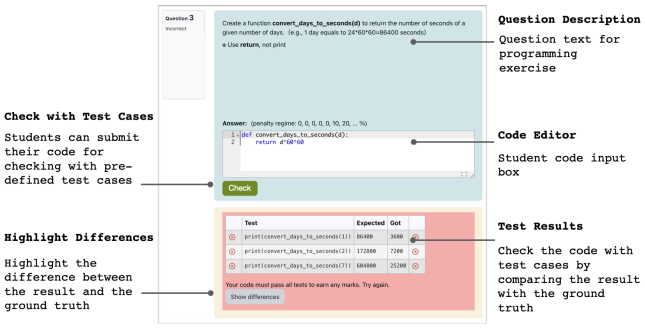

Figure 2: CodeRunner interface in Moodle.

RQ1: What cognitive difficulties (syntactic, conceptual, and strategic) emerge in programming tasks, and how do they differ between high and low prior-knowledge learners?

RQ2: What visual attention and behavioral transitions across task-relevant states emerge, and how do they differ between high and low prior-knowledge learners?

RQ3: What physiological regulation patterns/indices emerge, and how do they differ between high and low prior-knowledge learners?

2. RELATED WORK

Automated assessment tools are widely used in introductory programming because executable submissions enable scalable, consistent evaluation and rapid feedback [2, 13]. In the EDM and LA field, AAT logs (e.g., attempts, compiler outcomes, timestamps, and pass or fail test results) have been mined to model performance, persistence, and iterative behaviors in problem-level analyses [20, 1, 16, 15]. However, similar log traces can reflect different underlying processes, motivating process-oriented modeling beyond outcome indicators.

To interpret these ambiguous traces, computing education research commonly adopts a multi-layer knowledge framework with syntactic knowledge of language features, conceptual understanding of execution and constructs, and strategic knowledge for problem solving and debugging [21, 28, 34]. Large-scale analyses of submission corpora further show that student errors span additional categories (e.g., misinterpretation or carelessness), cautioning that code-only evidence may under-specify underlying causes [3]. Recent work operationalizes closely related difficulty categories (syntactic, conceptual, strategic) with explicit definitions and expert labeling [12], while semi-automated approaches such as code-embedding-based clustering have been proposed to discover problem-specific misconceptions from incorrect submissions at scale [31]. These lines of work support interpretable difficulty characterization, but typically do not connect difficulties to concurrent attention allocation and regulation dynamics.

To bridge this gap, complementary modalities provide process evidence that logs alone cannot. Eye-tracking studies in programming report systematic differences in attention strategies across skill levels and performance, motivating transition-based analyses over task-relevant regions and representations [25, 11, 5]. Physiological sensing has also been used to estimate cognitive effort and affect during programming and code comprehension (e.g., via EDA and heart-rate-related measures), with validation work supporting wearable instrumentation for more naturalistic settings [7, 23, 10]. Methodologically, multimodal learning analytics provides frameworks for synchronizing and fusing heterogeneous streams, highlighting the role of fusion design choices for validity and interpretability and showing benefits over single-modality models [26, 4, 24, 9, 33, 27].

While prior multimodal work demonstrates feasibility in programming education [19], relatively few studies jointly link AAT log-derived cognitive difficulties, attention transitions, and physiological regulation in authentic AAT-based programming task solving. Building on these strands, our study synchronizes AAT logs, eye movements, and wearable physiology to examine how these process indicators co-occur and differ by prior knowledge.

3. METHOD

3.1 Participants

Twenty-two university students voluntarily participated in this study (14 males and 8 females, with an average age of 24). Participants were recruited through campus announcements at a national university in Japan and included both undergraduate and graduate students from diverse academic disciplines. Programming experience ranged from no prior experience to nine years, covering both novice and experienced learners. The study protocol was reviewed and approved by the authors' university Research Ethics Committee and conducted in accordance with institutional guidelines for human-participant research. Participants provided written informed consent and could withdraw at any time.

3.2 Study Design and Learning Tasks

The overview of the study procedure is shown in Figure 1. This study was conducted in a controlled laboratory environment. Firstly, the students completed a pre-test and pre-questionnaire after a brief experimental introduction. Then the students were asked to access an introductory programming course in the Moodle learning management system (LMS). They were asked to read the lecture's introductory materials, which covered fundamental concepts in Python programming (e.g., basic functions) and solve four beginner-level programming questions using CodeRunner, an open-source Moodle plugin automated assessment tool [17]. Students were given the flexibility to complete the task at their

Table 1: Coding scheme for student cognitive difficulties, descriptions, and examples.

Difficulty	Description	Example
Syntactic	Misunderstanding of syntactic facts related to a particular programming language or failure on applying rules of syntax.	(1) Missing colon in `def` function header: `def print_morning print("")` (2) Non-standard symbols (fullwidth parentheses in function) (3) Wrong newline escape (uses /n instead of \n)

Conceptual	Misunderstanding of programming constructs or execution semantics.	(1) `return` vs. `print` confusion (prints but should return):
		`def convert_days_to_seconds(d): print(d*86400)`
		(2) Identifier misuse (uses undeclared name):
		`def repeat_five_times(s): print(sssss)`
		(3) Misunderstanding "repeat 5 times" (single call / one line):
		`def repeat_five_times(s): print(s,s,s,s,s)`

Strategic	Difficulties applying programming to solve novel problems by design, coding, and test.	(1) Task confusion (wrong function name than specified) `def print_morning(): print("...") ...` (2) Output-format planning issue (unwanted newlines): `for i in range(5): print(s)` (*missing* `end=""`)

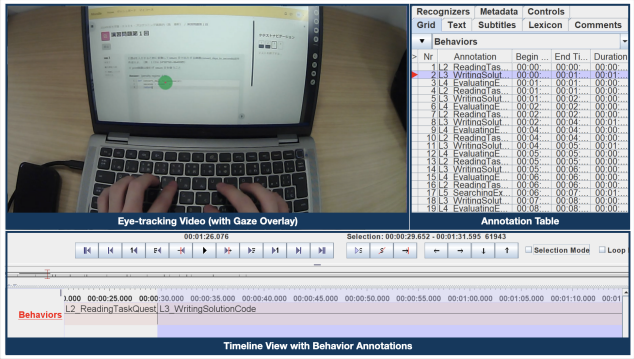

Figure 3: ELAN software used to annotate learning behaviors from eye-tracking videos.

own pace within a 35-minute learning session. An example CodeRunner question is shown in Figure 2. They could read the problem statement, input their code, and submit their solutions to be automatically checked against pre-defined test cases.

Students wore a 200-Hz Pupil Core eye tracker while solving programming tasks. Pupil Core (Pupil Labs GmbH, Berlin, Germany) is a pair of eye-tracking glasses endowed with two infrared real-time eye cameras and an environmental camera focused straight ahead of the screen. The eye-tracking screen data was recorded from the cameras and processed via the Pupil Player software later. Students also wore an EmbracePlus wristband before and during the learning session. They spent approximately 20 minutes in the preparation stage before they started 35-minute programming tasks. EmbracePlus wristband is a medical-grade wearable device that offers real-time physiological data collection [6]. The wristband embeds 3-axis accelerometer, electrodermal activity, temperature, and gyroscope sensors. It is a non-invasive device worn like a wristwatch, minimizing any discomfort during usage.

After completing the learning session, all participants took part in semi-structured, face-to-face interviews. The interviews probed students' learning experiences, focusing on perceived successes as well as aspects of the learning process that required improvement.

3.3 Data Collection and Analysis

Students' prior knowledge of Python programming was assessed using a 10-item pre-test covering core concepts, including data types, control flow, functions, and basic syntax in Python. Based on their pre-test scores, students were classified into two prior-knowledge groups: high prior-knowledge who scored 8 or higher out of 10 ($n = 10$), and low prior-knowledge who scored 6 or lower ($n = 12$). The cut-off leverages a natural gap in the distribution (no student scored 7), producing clearly separated groups for subsequent multimodal comparisons.

A pre-questionnaire was administered to collect participants' demographic information, including gender, age, and academic major.

All student interactions with the Moodle platform were logged automatically. CodeRunner problem-solving behavior was captured in learning logs, including assessment logs, submitted codes, and system feedback. The raw logs contained question-level information, including question contents, question access timestamps, and question start times, as well as attempt-level step histories for each learner and question. Each step record included the step number, timestamp, action type, submitted answer, correctness state, score, and CodeRunner feedback such as error messages. These learning logs were classified into cognitive difficulties including syntactic, conceptual, and strategic types, adopted a prior conceptual framework [28]. The coding scheme is summarized in Table 1.

Students' behaviors during programming tasks were captured using eye-tracking video recordings. The raw eye-tracking data consisted of time-stamped gaze recordings collected with the Pupil Core eye tracker and synchronized screen recordings of students' interactions with the Moodle-based CodeRunner environment. Fixations were automati-

Table 2: Coding scheme of student learning behaviors during programming tasks.

Code	Behavior	Description
Lecture	Watching Lecture Material	Students viewed the instructional materials provided in the Moodle course.
Question	Reading Task Question	Students read and examined the programming task statement.
Code	Writing Solution Code	Students wrote program code in the coding box to solve the task.
Fail	Execution Results Fail	Students submitted their code for automated assessment, but it failed one or more test cases or returned an execution error.
Pass	Execution Results Pass	Students submitted their code for automated assessment, and it successfully passed all test cases.
Search	Searching External Resources	Students searched the internet for task-related information, programming concepts, or error explanations. Use of generative AI tools like ChatGPT was not allowed.
Note	Taking Notes	Students wrote notes or sketched ideas on paper during the learning session.

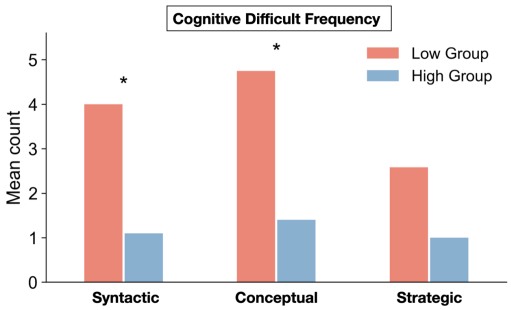

Figure 4: The distribution of cognitive difficulties faced by learners with high and low prior-knowledge.

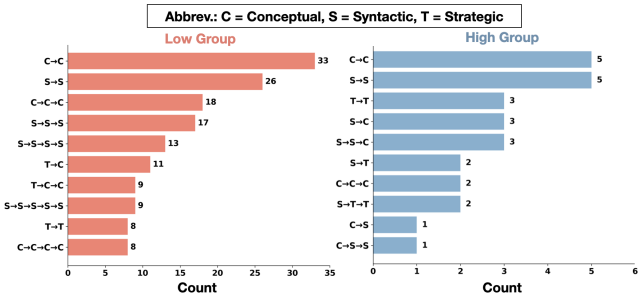

Figure 5: Top 10 most frequent cognitive transition sequences by group.

cally extracted in Pupil Player using the dispersion-threshold identification (I-DT) algorithm, with a dispersion threshold of 1.5° visual angle and a minimum fixation duration of 100 ms [29]. The synchronized screen and gaze videos were manually annotated to extract observable programming behaviors as shown in Figure 3. Following prior research on SRL in programming [32], seven programming behaviors were coded as summarized in Table 2. These behaviors captured how students engaged with lecture materials, understood problem requirements, created and evaluated solutions, sought external information, and noted their thinking processes. The annotated behaviors were used to compute behavioral frequency, duration, and transitions, enabling comparison of behavioral dynamics across different task contexts. Specifically, temporal behavioral sequences were extracted at the programming question level, with each programming question treated as an independent learning episode.

To compare programming behaviors between groups, we analyzed both overall activity and temporal dynamics. For frequency and duration measures, we used independent-samples t-tests or Wilcoxon rank-sum tests after a normality check. To model behavioral dynamics, we applied Transition Network Analysis (TNA) [30], representing each learner's question-level sequence as a weighted directed network (nodes = behavioral states; edges = transition probabilities). Transition probabilities were aggregated within each group. Between-group differences in transition probabilities were tested using Fisher's exact test.

Students' physiological signals were collected using the EmbracePlus wristband during the learning session. The raw data consisted of time-stamped electrodermal activity (EDA) and blood volume pulse (BVP) streams synchronized with the task timeline. Because wrist-based physiological data are sensitive to movement artifacts and physiological responses can appear with a delay after cognitive or affective events, we used a window-based analysis. Specifically, signals were segmented into non-overlapping 1-minute windows and aligned with two task stages: preparation and programming. We derived four features: (1) tonic EDA as log-transformed skin conductance level (log(SCL)); (2) phasic activity as log1p-transformed skin conductance response rate (log1p(SCR/min)); (3) heart rate as mean beats per minute (BPM); and (4) heart-rate variability as log-transformed RMSSD (log(RMSSD)). To reduce between-person baseline differences, we computed within-person z-scored composites: (5) an *Arousal Index* as the mean of z-scored log(SCL) and log1p(SCR/min), and (6) a *Regulation Index* as z-scored log(RMSSD). We tested main effects and interactions of *Group* (low vs. high prior knowledge) and *Stage* (preparation vs. programming) on each feature and index using mixed-effects models.

4. RESULTS

4.1 Log-based Cognitive Difficulties (RQ1)

Figure 4 shows the distribution of cognitive difficulties in the syntactic, conceptual and strategic types faced by learners with high and low prior-knowledge. Low prior-knowledge students produced significantly more *Syntactic* (U = 97.0, p = .037, r = 0.62) and *Conceptual* (U = 96.5, p = .037, r = 0.61) difficulty attempts than high prior-knowledge stu-

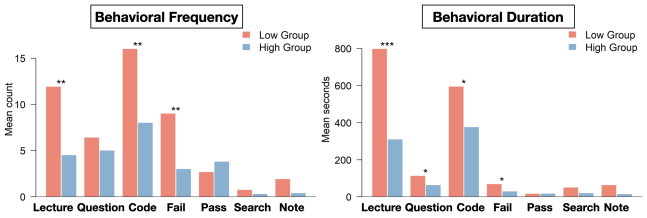

Figure 6: Programming behavioral differences in frequency and duration between high and low prior-knowledge learners.

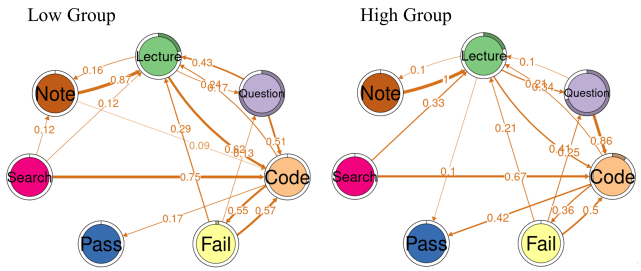

Figure 7: Transition network of programming behaviors between high and low prior-knowledge learners. Nodes represent each coded behavior. Edges represent transition probabilities between nodes.

dents. *Strategic* differences trend higher for low prior-knowledge students but were not significant (U = 83.5, p = .119).

We further analyzed sequence patterns by extracting learner's attempt-level contiguous subsequences. Mann–Whitney U tests show no subsequence differences that remained significant ($p_{\text{Holm}} = 1.0$ for all). Low prior-knowledge learners exhibited more persistence of conceptual difficulty, more longer repeated syntactic failures, and more strategic-to-conceptual shifts, whereas high prior-knowledge learners show fewer failure episodes overall and fewer transitions. Figure 5 shows top 10 most frequent cognitive transition sequences for low (left) and high (right) prior-knowledge groups.

4.2 Eye-tracking Attention Dynamics (RQ2)

Figure 6 shows the programming behavioral differences in frequency and duration between high and low prior-knowledge learners. Results show that low prior-knowledge learners spent significantly more time on Lecture viewing (M = 797s vs. 310s, p < .001), Question reading (M = 113s vs. 63s, p = .017), Code writing (M = 594s vs. 376s, p = .033), and examining Fail results (M = 69s vs. 29s, p = .012). Notably, Lecture duration showed the largest effect size (d = 1.81), indicating that low-group learners spent more than double the time revisiting lecture materials.

Figure 7 shows the transition network of programming behaviors between high and low prior-knowledge learners. Seven significant transition differences were found between low and high prior-knowledge learners using Fisher's exact test. The high prior-knowledge group followed a more execution-oriented path, with higher *Question*→*Code* (86.0% vs. 50.6%; $p = 5.1 \times 10^{-5}$) and *Code*→*Pass* (42.5% vs. 16.8%; $p = 1.9 \times 10^{-5}$), and fewer *Code*→*Fail* transitions (36.2% vs. 55.5%; $p = 5.0 \times 10^{-3}$). In contrast, the low prior-knowledge group relied more on materials, showing higher *Question*→*Lecture* (42.9% vs. 10.0%; $p = 5.9 \times 10^{-5}$) and *Lecture*→*Code* (62.2% vs. 41.5%; $p = 3.0 \times 10^{-2}$). Lecture use also differed in integration: high prior-knowledge learners more often returned to refine task understanding (*Lecture*→*Question*: 34.1% vs. 17.0%; $p = 2.8 \times 10^{-2}$) and were more likely to reach success after consulting materials (*Lecture*→*Pass*: 9.8% vs. 0.0%; $p = 2.6 \times 10^{-3}$). Overall, high prior-knowledge learners progressed more directly from problem understanding to coding and success, whereas low prior-knowledge learners showed a lecture-mediated and more failure-prone workflow.

4.3 Physiological Regulation Signals (RQ3)

Figure 8 presents minute-level physiological trajectories (panels a–d) and Group × Stage comparisons (panels e–h) for low and high prior-knowledge learners. Panels (a)–(d) show GAM-smoothed group trajectories with ±1 SEM bands for tonic EDA [log(SCL)], phasic SCR rate [log1p(SCR/min)], heart rate (BPM), and RMSSD [log(RMSSD)], respectively. Mixed-effects models controlling for MET indicated a robust main effect of stage for three features: tonic EDA increased from Preparation to Programming ($b = 0.33$, $p < .001$), phasic SCR rate increased ($b = 0.24$, $p < .001$), and RMSSD decreased ($b = -0.36$, $p < .001$), whereas heart rate showed no stage shift ($b = -0.12$, $p = .859$). A significant Group x Stage interaction was observed for phasic SCR rate (b = -0.21, p = .006; panel f), indicating a larger Programming-related increase for low prior-knowledge learners than for high prior-knowledge learners. No Group × Stage interactions were found for tonic EDA ($p = .680$), heart rate ($p = .260$), or RMSSD ($p = .095$).

Figure 9 summarizes the physiological results using within-person standardized, minute-level composite indices. Panels (a–b) show GAM-smoothed trajectories (±1 SEM) for the Arousal Index, combining tonic SCL and phasic SCR activity, and the Regulation Index, based on RMSSD. These smoothed trajectories indicate relative changes in physiological activation and regulation across the preparation and programming stages. Panels (c–d) show the mixed-effects model estimates for Group × Stage effects. Arousal increased from Preparation to Programming ($b = 0.59$, $p < .001$), with no Group × Stage interaction ($b < 0.01$, $p = .992$), suggesting comparable increases in sympathetic activation for both prior-knowledge groups. Regulation decreased from Preparation to Programming ($b = -0.52$, $p < .001$), indicating lower RMSSD-based regulation during active programming. This decrease was qualified by a significant Group × Stage interaction ($b = 0.40$, $p < .001$): low prior-knowledge learners showed a larger programming-related reduction in the Regulation Index than high prior-knowledge learners.

5. DISCUSSION

In this study, we conduct a multimodal study that synchronizes submission logs, eye tracking, and wearable physiology to characterize how cognitive difficulties, visual attention transitions, and physiological regulation unfold during an AAT-based programming learning environment and how they differ by prior knowledge. Across learning log, attention-based behavior, and physiological signal, the re-

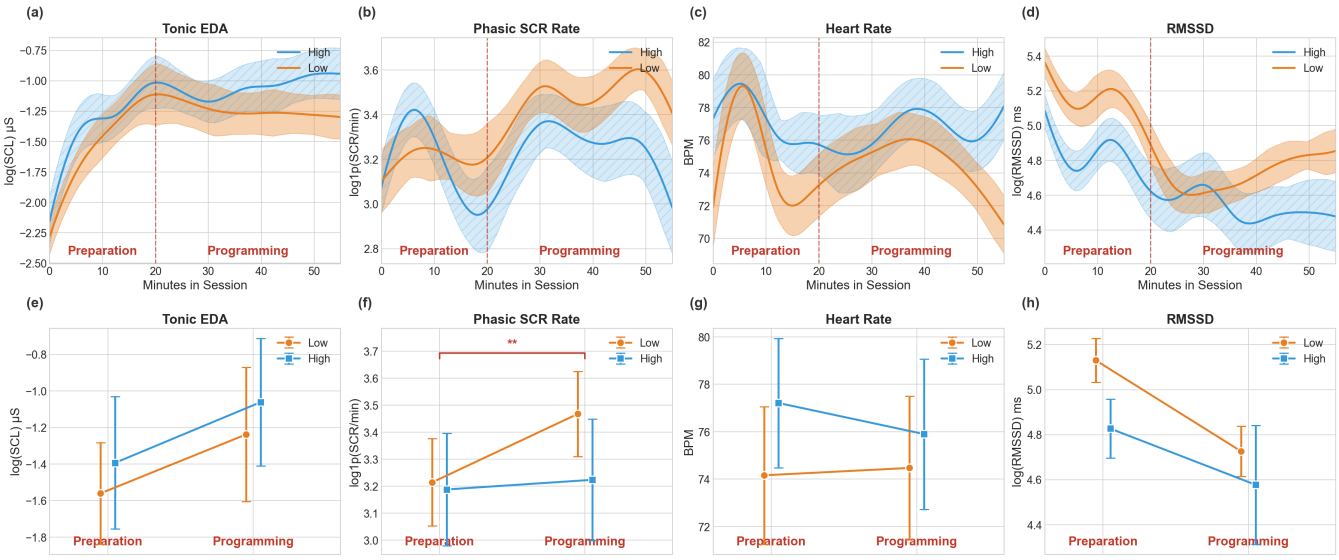

Figure 8: Physiological trajectories and Group × Stage effects for low and high prior-knowledge learners.

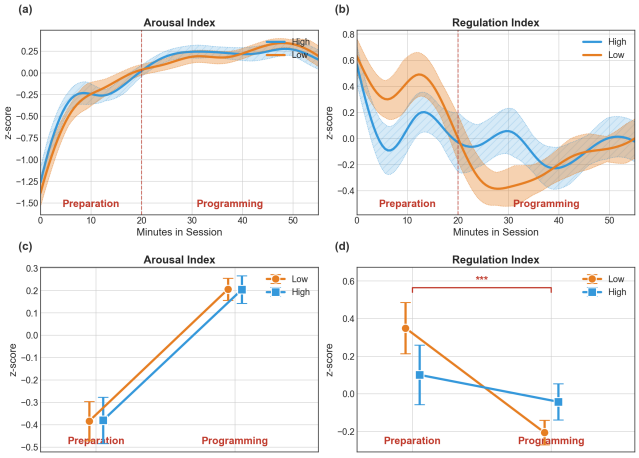

Figure 9: Higher-order physiological indices (within-person z-scored) and Group × Stage effects for low and high prior-knowledge learners.

sults consistently indicate that prior knowledge shapes how learners allocate resources and regulate effort during AAT-based programming.

Syntactic and conceptual difficulties. Low prior-knowledge learners exhibited more frequent difficulty episodes, particularly in *syntactic* and *conceptual* categories, whereas strategic differences were weaker. Sequence-level analyses suggested that low prior-knowledge learners experienced more extended failure episodes (e.g., repeated syntactic failures) and sustained conceptual difficulty, while high prior-knowledge learners showed fewer difficulty episodes and less complex difficulty transitions overall.

Lecture-mediated cycle vs. execution-oriented workflow. Eye-tracking measures revealed that low prior-knowledge learners spent substantially more time consulting learning materials and feedback, including longer lecture viewing, more question rereading, longer code-writing time, and more time inspecting failing outcomes. Transition Network Analysis further showed distinct workflows: high prior-knowledge learners followed a more execution-oriented pathway. Lecture use also differed qualitatively: high prior-knowledge learners more often returned from lecture to the question and were more likely to succeed after lecture consultation.

Increased arousal and reduced regulation during programming. The shift from Preparation to Programming elicited a clear physiological change in both groups: sympathetic arousal increased (higher tonic and phasic EDA) and parasympathetic regulation decreased (lower RMSSD), while heart rate remained comparatively stable. Importantly, group differences emerged in *dynamic regulation* rather than average arousal: low prior-knowledge learners showed a larger programming-related increase in phasic SCR and a larger decrease in the Regulation Index, indicating stronger moment-to-moment arousal reactivity and weaker regulation during programming.

Multimodal analytics based learner model. Taken together, the multimodal results suggest a coherent pattern: low prior-knowledge learners encountered more basic (syntax/concept) breakdowns, engaged in more material- and feedback-driven cycles, and showed heightened physiological reactivity with larger reductions in regulation during programming. In contrast, high prior-knowledge learners progressed more directly from problem understanding to code execution and success, and their lecture use appeared more selective and integrative. These findings motivate learner models and supports that adapt not only to error types but also to workflow dynamics and regulation states during feedback-intensive programming.

Implications for adaptive support and learning design. Our findings may have implications for adaptive support and learning design in programming education. For low prior-

knowledge learners, supports should prioritize (a) syntax-concept remediation (common error patterns, execution semantics checks), and (b) workflow guidance that helps convert lecture consultation into progress (e.g., prompts that connect a specific lecture snippet to a concrete code revision, or structured question rereading before coding). For high prior-knowledge learners, lighter supports that preserve autonomy may suffice (e.g., optional checks for edge cases or output formatting). Physiological findings suggest that regulation signals can complement logs/gaze to flag moments where learners may benefit from brief metacognitive prompts (e.g., pause–plan–test routines) or reduced cognitive load (e.g., simplified feedback, stepwise hints) rather than repeated automatical feedback.

Limitations. Several limitations should be noted. First, the sample was relatively small and drawn from a single university, which may limit the generalizability of the findings. Thus, our results should be interpreted as exploratory, process-level evidence from multimodal triangulation in AAT-based programming. Second, categorizing learners into low and high prior knowledge enabled interpretable contrasts but may obscure graded relationships between prior knowledge and multimodal processes. Third, wrist-worn physiological signals can be noisy, highly individualized, and may lag behind task events and therefore our minute-level aggregation and stage-level comparisons may miss event-locked regulation changes.

6. CONCLUSION

This work contributes temporally aligned evidence linking difficulty types, attention transitions, and regulation dynamics in an authentic AAT setting. It demonstrates the value of synchronizing AAT logs, eye tracking, and wearable physiology to model programming task solving beyond outcome-based indicators. Our findings motivate process- and regulation-aware learner models and targeted supports (e.g., difficulty-specific scaffolds and workflow guidance) to better assist learners who struggle in AAT-based programming environments.

ABSTRACT

Intelligent Tutoring Systems often grant learners shared control over skill and problem selection. This choice brings motivational and metacognitive benefits. At the same time, past literature suggests that learners exhibit diverse preferences and strategies in selecting tasks, for instance, by avoiding challenge. Although underexplored, differences in learner task-selection strategies may interact with mastery learning systems that optimize task-selection based on estimated knowledge, potentially leading to undesirable student-level differences in learning outcomes. Algorithmic constraints on problem selection may help mitigate this issue. However, this possibility has not been comprehensively explored in prior work, in part because testing such constraints in real-world classrooms is costly. We propose a simulation-based framework to observe how varying learner task-selection strategies combined with system constraints shape mastery learning efficiency. Using interaction data from 261 students across two mathematical domains with different problem structures (equation solving, graph interpretation), we simulate common task-selection strategies such as Weakness Targeting and Interleaving, grounded in prior literature. We then evaluate how these strategies affect overpractice as a common measure of mastery learning efficiency. Results show substantial variability in efficiency across strategies, with risk-averse strategies producing higher levels of overpractice, especially for more complex multi-step problems. Targeted system constraints significantly reduce these inefficiencies for maladaptive strategies while having minimal impact on already efficient strategies. Together, these findings demonstrate how simulation grounded in real student data can support data-driven redesign of shared-control tutoring systems by identifying when and where constraints are most beneficial prior to classroom deployment.

1. INTRODUCTION

Mastery-based learning is widely adopted in Intelligent Tutoring Systems (ITS) to personalize instruction and ensure learners demonstrate proficiency in prerequisite skills before advancing [14, 19]. Although ITS typically do not involve learners in the adaptive task-selection process, prior work has shown that involving learners by allowing them to express or act on task-selection preferences can yield motivational and metacognitive benefits, including increased engagement, perceived autonomy, and reflection on learning progress [5, 8, 17, 20]. However, differences in learner task-selection strategies can introduce substantial inefficiencies in mastery-based learning, particularly when learners choose problems that involve skills they have already mastered or avoid challenging ones [19, 23]. Prior research has shown that learners adopt diverse task-selection strategies such as Strength Targeting, Weakness Targeting, Interleaving, or Blocking [6, 10, 17]. While some strategies align well with mastery-based learning objectives, others can result in excessive overpractice and delayed progression, particularly in domains with multi-step problem structures where mastered skills frequently reappear.

Studying how different learner strategies paired with task-selection constraints through classroom experiments is costly, time-consuming, and may expose learners to suboptimal learning experiences. Alternatively, simulation studies with real learner interaction data enable systematic and efficient comparison of learner strategies and instructional design choices before deployment [16, 19, 23]. By modeling how different forms of learner control and system guidance shape learning trajectories, simulation offers a scalable method for identifying inefficiencies and testing corrective mechanisms before they affect real students.

We present a simulation-based framework for analyzing how learner task-selection strategies interact with system constraints to shape mastery-based learning efficiency in ITS. Using interaction data from two mathematical domains (equation solving and graph interpretation), we simulate common learner strategies and evaluate their effects using measures of overpractice. This approach enables controlled comparison of learning control and system-control configurations, providing insights into when targeted scaffolding is necessary

to mitigate inefficiencies while preserving learner choice. In sum, our research question is as follows:

RQ. How do different learner task-selection strategies, combined with system constraints, affect the efficiency of mastery-based learning in ITS?

2. RELATED WORK

2.1 Task-Selection Strategies in ITS

Mastery learning frameworks advance students only after demonstrating mastery of prerequisite skills, using criteria based on performance [19]. This ensures competence but can create inefficiencies, as some skills become overpracticed while others are neglected [23]. In many modern ITS, learners are increasingly involved in selecting which skills or problems to practice, often supported by learning analytics and open learner models (OLMs) that make progress and mastery visible [5, 17]. Allowing learners to make such choices is motivated by self-determination theory, which emphasizes autonomy as a key driver of intrinsic motivation, engagement, and persistence in learning [22]. Prior work in educational data mining and ITS shows that learners adopt diverse task-selection strategies [6]. Studies show that when learners freely select skills or problems, they pursue strategies of uneven effectiveness, indicating that control alone rarely improves outcomes and can even hinder them if left unsupported [20]. Some choose familiar tasks, others target weaknesses [6]; some interleave across skills, while others block practice within a single skill, often shaped by confidence and goals [10]. These strategies can nurture persistence and reflection, but also cause inefficiencies, such as overpractice of mastered skills or avoidance of challenges. Understanding how learners naturally manage practice is therefore essential, both to amplify productive strategies and to counter maladaptive ones. Despite this, little research has systematically examined how such strategies interact with system-level supports like constraints, guidance, or explanations.

2.2 System Constraints and Simulation

To address variability in learner behavior, ITS increasingly combines learner choice with system-level constraints that guide task-selection while preserving agency, a paradigm often described as shared student-system control over task-selection. Prior work shows that constrained problem-selection and guided choice can reduce overpractice and improve efficiency without fully removing learner control [17, 23, 24]. However, evaluating how different learner strategies interact with such constraints through classroom studies is costly and risks exposing students to suboptimal learning conditions.

Simulation studies have therefore become increasingly valuable in education research, especially where in vivo experimentation is infeasible or cost-prohibitive [18]. In addition, deploying poor algorithms can be harmful to participants. Simulation enables systematic exploration of both learner strategies and shared-control mechanisms, such as weightings, recommendations, and explanation styles, in a controlled environment. Prior research demonstrates that simulated learners can reproduce realistic learning trajectories and support the development of novel optimization techniques for tutoring systems [23]. Rather than aiming to predict individual learning outcomes, simulation enables comparative analysis of alternative design configurations under consistent assumptions [16, 19]. In this work, we build on this line of research by using simulation to examine when shared-control constraints are necessary to mitigate inefficiencies arising from specific learner task-selection strategies.

3. METHODS AND MATERIALS

3.1 Datasets

We used two datasets to specify model parameters and enhance validity. Following [23], we defined the most common solution pathways in the data and based the simulations on them [13]. The first dataset is on equation-solving and used an open-source dataset available on PSLC DataShop (datasets #5549 and #5604), collected from IRB-approved middle school studies using the APTA ITS for linear equation solving [1, 15]. The dataset includes students in grades 6–8 attending two public schools in the eastern United States and contains over 10,000 step-level interactions with multi-step equation problems [14]. To model authentic first-attempt problem solving, only initial responses were retained, and steps involving hints were treated as incorrect [14]. The step-level structure and repeated use of skills enable reconstruction of typical solution paths, which form the basis for simulating learning trajectories and task-selection strategies. This dataset contains 58 problems and 10 skills. The average number of skills that appeared in a problem was 5.67 ± 2.47.

We additionally used another DataShop dataset based on graph interpretation (#5360) [15]. This dataset consisted of classroom transaction data from the Mathtutor ITS, collected through IRB-approved studies with 97 ninth-grade students in a U.S. high school. Students alternated between paper practice and Mathtutor across three units on linear graphs, with the problem decomposed into step-level interactions (though we only used data from the ITS condition). The dataset represents another domain of multi-step problem solving where students may engage in overpractice to improve generalizability beyond the equation-solving data. This dataset contains 31 problems and 13 skills. The average number of skills that appeared in a problem was 8.57 ± 8.41.

The datasets differ in problem length and problem-skill composition: graph interpretation involves more skills and steps per problem than equation solving. Because these factors affect overpractice [23], this enables evaluation of skill and problem-selection strategies across varied problem types.

3.2 Learner Simulation Methods

We use a simulation-based approach to model student learning under different task-selection strategies in a mastery-based ITS. We specifically use two widely used student modeling approaches in educational data mining research. We use the Additive Factors Model (AFM; [7]) to simulate step-level performance and Bayesian Knowledge Tracing (BKT; [9]) to model knowledge evolution over time. The simulation framework is built on real student interaction data using open-source learner simulation libraries described in Xia et al. [23].

To estimate skill difficulty and learning parameters for our two datasets, we fit both AFM and BKT to the PSLC

DataShop and MathTutor ITS data collections and use the learned parameters to drive the student simulations. Each problem is associated with a typical solution path derived from the most frequent skill-application sequences in the data [21]. During simulation, student responses are sampled at each step according to the AFM-predicted probability of correctness, and both AFM and BKT states are updated after each interaction. The resulting BKT mastery estimates are then used to guide subsequent problem-selection. Our simulation and analysis code is open-source.[1].

AFM models the probability of a correct response as a logistic function of a global intercept, a student ability term, and additive skill-specific difficulty and practice effects. Specifically, calculations are made using information such as the set of skills associated with a problem step, the difficulty of these skills, and the attempts the student has previously made for these skills. BKT models student learning as a hidden Markov process in which each skill has a binary latent state: either learned or unlearned. The model updates mastery using observed responses and four parameters: Prior knowledge estimates (p_{init}), learning rate (p_{learn}), guess rate (p_{guess}), and slip rate (p_{slip}).

Upon receiving a student response, BKT updates the estimated mastery level using Bayes' rule. A correct answer increases the mastery probability, which adjusts the potential for guessing, while an incorrect answer decreases the probability, accounting for possible slips. A skill is considered mastered once the posterior probability surpasses a predefined mastery threshold, in our case 95%, consistent with prior ITS research [2]. The initial values of the BKT parameters are based on the following default values in TutorShop: $p_{\text{init}} = 0.25$, $p_{\text{learn}} = 0.22$, $p_{\text{guess}} = 0.2$, and $p_{\text{slip}} = 0.1$.

3.3 Simulation Overview

Each simulation allows 1,000 learners to progress through a set of skills until mastery is achieved. The simulation is designed to support controlled comparison of learner strategies and system constraints under standardized conditions. The simulation models mastery learning as a repeated problem-level decision cycle. The iterative cycle of task-selection, problem-solving, and mastery updating defines a learning path for each simulated learner. Specifically, a learning path is represented as the sequence of skills selected and problems attempted over time in combination with the changing mastery estimates. As task-selection decisions are made based on the learner's current knowledge state and updated after each simulated problem attempt, the resulting trajectories reflect the learner's emergent path through an adaptive task sequence. Between problems, a simulated learner selects a skill to practice based on a predefined task-selection strategy, optionally shaped by system-imposed constraints on the available skill choices. Once a skill is selected, the system chooses a problem that uses that skill, potentially applying additional problem-selection constraints. This modeling choice reflects a common shared-control setup in mastery-based ITS, where learners select skills, and the system selects corresponding problems, but does not capture all possible forms of task-selection [2, 12].

[1] `https://github.com/conradborchers/sim-skill-selection`

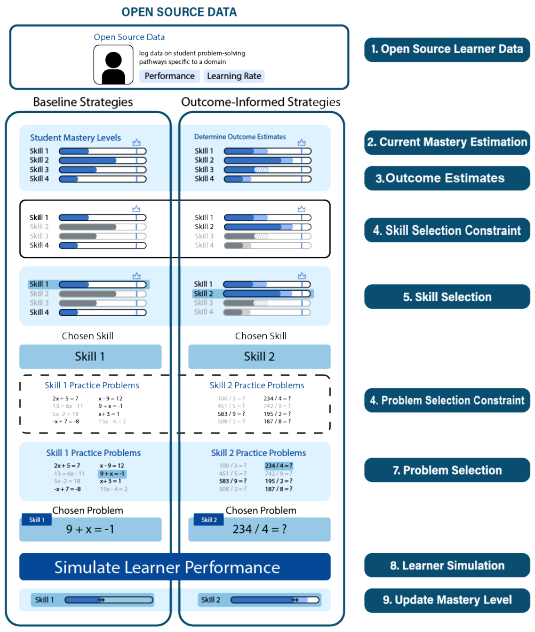

Figure 1: Simulation Methodology Summary.

The simulated learner then attempts the selected problem, which may consist of multiple steps, each mapping to at least one skill. The steps are simulated sequentially, with performance generated probabilistically based on the learner's current knowledge state and step difficulty. Mastery estimates are updated after each step, but the learner does not make additional choices until the entire problem has been completed. After the problem attempt concludes and mastery estimates are updated, the learner again selects a skill for the next problem based on their updated skill mastery estimates, and the cycle repeats.

This structure mirrors the way that learners can select tasks when interacting with shared-control mastery-based ITS, where strategic decisions are made between problems rather than within them [2, 17]. By grounding step-level performance and mastery updates in parameters estimated from real student data, the simulation produces realistic learning trajectories while enabling controlled comparison of how different learner task-selection strategies and system constraints affect mastery learning efficiency. Figure 1 summarizes this iterative problem-selection-practice loop.

Below, we elaborate on the individual components of the simulation framework:

1. **Open Source Learner Data** We begin by using open-source log data from both middle school and high school math ITS, which contains detailed records of student interactions and performance across a range of equation-solving and graph-interpretation skills, respectively (see Section 1).

2. **Current Mastery Estimation** The estimated mastery levels for each skill present in the dataset are calculated after every practice opportunity.

3. **Outcome Estimates** For strategies that specifically rely on outcome-estimations, we compute the projected mastery outcomes under three scenarios: best case, usual case, and worst case.

4. **Task-Selection Guidance** Front-end task-selection guidance simulates UI cues by restricting the pool of selectable skills to those closer or further from the mastery threshold, shaping learner decisions without altering algorithms.

5. **Task-Selection** A skill is selected using either a general strategy (e.g., Strength Targeting, Interleaving) or an Outcome-informed strategy (e.g., Maximize Usual Case, Minimize Worst Case Loss), simulating different learner decision-making behaviors.

6. **Problem-Selection Constraint** Once a skill is selected, a system control constraint introduces bias in the subsequent problem-selection process based on problem difficulty, modeling how backend design influences the learning path.

7. **Problem-Selection** A specific problem is randomly drawn from the available pool associated with the selected skill, either randomly or following any imposed system control constraints.

8. **Learner Simulation** The simulated student attempts the selected problem step, and performance is determined probabilistically using AFM, based on current skill mastery and step difficulty.

9. **Update Mastery Level** Following the simulated attempt, mastery estimates are updated using BKT, and the simulation loop repeats until all skills reach mastery or a stopping condition is met.

3.4 Task-Selection Strategies

We model learner task-selection using predefined decision rules that determine which skill a simulated learner chooses to practice at each step. The eight selected strategies are designed to reflect commonly observed patterns of learner behavior in mastery-based tutoring systems and are applied consistently across all simulation conditions.

3.4.1 Baseline Task-Selection Strategies

We implement four baseline strategies drawn from prior work on learner practice behavior. **Strength Targeting** prioritizes skills that are close to mastery, while **Weakness Targeting** prioritizes skills with the lowest estimated mastery. **Interleaving** alternates practice across multiple skills, whereas **Blocking** concentrates practice on a single skill until mastery is achieved. These strategies capture a range of common learner approaches to managing practice and have been widely studied in educational psychology and ITS research. Finally, a **Random** strategy selects skills at random and serves as a control condition.

3.4.2 Outcome-Informed Strategies

In addition to baseline strategies, we model decision rules that select skills based on projected mastery outcomes under different assumptions about performance. **Maximize Usual Case Improvement** selects the skill with the greatest expected mastery gain, while **Maximize Usual Case Outcome** selects the skill with the highest projected post-practice mastery. **Minimize Worst Case Loss** represents a risk-averse strategy that selects the skill with the smallest potential decrease in mastery under unfavorable performance. This strategy is risk-averse because it prioritizes minimizing potential negative mastery outcomes over maximizing expected gains.

Together, these strategies enable systematic comparison of how different decision-making behaviors interact with system-level constraints to influence learning efficiency in mastery-based tutoring systems.

3.5 System Constraints

To examine how system design interacts with task-selection strategies, we introduce two system constraints that shape learning while preserving learner control over skill prioritization.

3.5.1 Task-Selection Constraints

Task-selection constraints limit the set of skills available for selection at each decision point based on current mastery estimates. We implement two variants. The *closer-to-mastery* constraint restricts selection to skills with proficiency levels nearest to, but below, the mastery threshold. The *further-from-mastery* constraint restricts selection to skills with lower proficiency levels, representing a weaker understanding. These constraints reduce learners' choice set without prescribing a specific selection strategy, allowing learners to retain control within a bounded decision space. We also simulate learners' interactions under unconstrained task-selection to provide a baseline for comparison.

3.5.2 Problem-Selection Constraints

Problem-selection constraints influence which problem is delivered after learners select a skill. Rather than selecting problems uniformly at random, the system applies biased sampling within the chosen skill. Problem difficulties are determined using a weighted average of the learners' past performance with skills present in problem steps. Under the *prefer-easier constraint*, problems associated with lower difficulty skills are assigned higher weight, while under the *prefer-harder constraint*, problems associated with higher difficulty skills are given higher weight. Once all the problem difficulty scores are assigned, they are normalized to form a multinomial distribution from which weighted random sampling is used to select a problem. These constraints operate independently of task-selection and affect only the execution of practice within a chosen skill.

3.6 Metric: Overpractice

We evaluate the impact of system constraints in ITS using **overpractice** as the primary outcome. Overpractice refers to continued practice of skills that have already reached mastery, a phenomenon that commonly arises in mastery-based tutoring systems [19, 23]. This particularly occurs when problems involve multiple skills or steps, as problems primarily based on already proficient skills may be chosen for including an unmastered component [14]. Overpractice has been studied as an inefficiency in mastery-based ITS, as it increases time on task without proportional learning benefits and can slow progression through the learning process

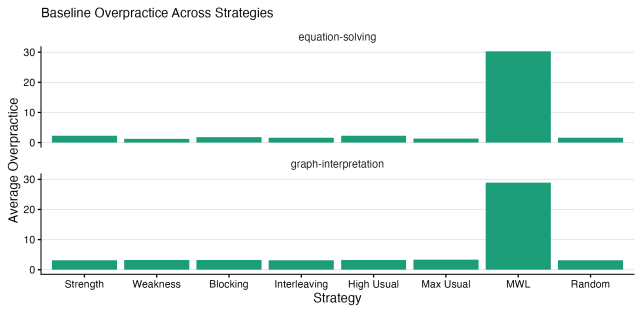

Figure 2: Baseline Average Overpractice Across Strategies for Both Datasets. MWL denotes the Minimize Worst Case Loss strategy.

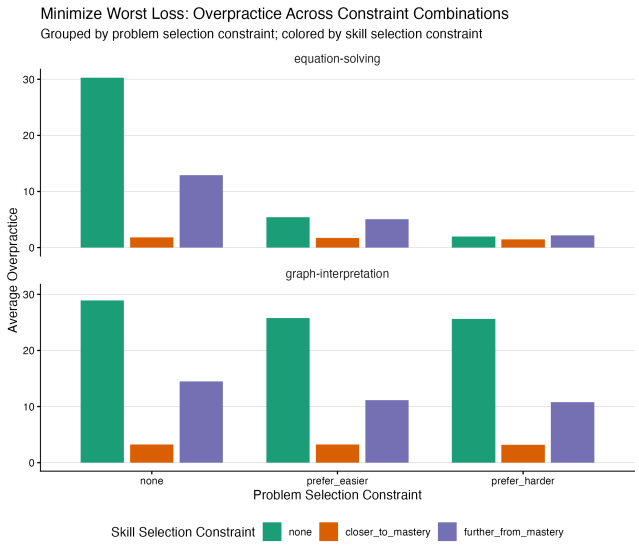

Figure 3: Average Overpractice for the Minimize Worst Case Loss Strategy with Task-Selection and Problem-Selection Constraints.

[16, 19, 23]. For each strategy-constraint condition, simulation runs produced data on the overpractice aggregated across all skills present in the dataset, yielding descriptive statistics, including mean and standard deviation. In addition to comparing means and effect sizes using Cohen's d, the analysis focused on determining which strategies and constraints resulted in the most efficient mastery learning, indicated by reduced overpractice. The findings helped identify optimal combinations of strategies and constraints that minimized unnecessary practice while maintaining mastery.

4. RESULTS

The results presented in Figures 2 and 3 summarize the average overpractice observed under different task-selection strategies and system constraint conditions. These values are computed by aggregating overpractice across all simulated learners and skills. This allows for direct comparison of learning efficiency across strategies and datasets.

4.1 Performance Across Strategies

Figure 2 compares baseline overpractice levels across all task-selection strategies without system constraints. Across both datasets, minimizing worst case loss was a clear outlier in terms of its average amount of overpractice. Without system constraints, using the Minimize Worst Case Loss strategy produced overpractice levels of 30.28 times in equation-solving and 28.93 times on average in graph-interpretation (Figure 2). In contrast, the average of the other seven strategies' overpractice amounts were 1.733 ± 0.383 and 3.223 ± 0.050 for the equation-solving and the graph-interpretation data sets, respectively. Additionally, the second-worst performing strategy for the equation-solving dataset was the Strength Targeting strategy. This indicates that informed risk-averse strategies are substantially less efficient than other strategies in self-guided systems.

On the other hand, in the equation-solving dataset, Weakness Targeting and Maximize Usual Case Improvement performed slightly better than other strategies, yielding the lowest overpractice of 1.26 and 1.29 average practice opportunities, respectively (Figure 2). This suggests that prioritizing less-mastered skills is a comparatively efficient approach.

4.2 Incorporating System Constraints

Figure 3 illustrates how task-selection and problem-selection constraints affect overpractice for the Minimize Worst Case Loss strategy. Introducing task-selection constraints significantly moderated outcomes for otherwise inefficient strategies. Most notably, when the risk-averse strategy (Minimize Worst Case Loss) was guided toward skills closer to mastery, the excess overpractice was sharply reduced from 30.28 to 1.83 times in equation-solving and 28.93 to 3.22 times in graph-interpretation relative to the unconstrained baseline, with large respective Cohen's d effect sizes of 1.87 and 1.86 (Figure 3). Task-selection constraints that prioritized skills further from mastery also improved efficiency, reducing overpractice to 12.88 and 14.46, respectively. By contrast, most other strategies were relatively unaffected by these constraints. Blocking, Interleaving, Strength Targeting, and Weakness Targeting all maintained stable levels of overpractice across conditions. Overall, the results indicate that specific forms of system control exert their strongest effects on risk-averse learners, while already efficient strategies show minimal change.

Problem-selection constraints also had a considerable effect on reducing inefficiencies in simulated learning. When paired with the Prefer Harder constraint, Minimize Worst Case Loss showed a greatly reduced overpractice value from 30.28 to 1.98 times in the equation-solving dataset, a large Cohen's d effect size value of 1.86, leveling the other strategies without the constraint (Figure 3). This suggests that system control constraints can help counterbalance risk-averse tendencies by increasing exposure to more challenging problems. The equation-solving dataset, where multi-step structures magnified redundancy, produced a stronger corrective effect when paired with the Prefer Harder constraint compared to graph-interpretation.

5. DISCUSSION

As learner control becomes increasingly common in ITS and other adaptive learning environments [4, 8, 20], understanding how differences in task-selection behavior affect learn-

ing efficiency is critical. Rather than assuming that learner choice uniformly benefits all students, our results demonstrate substantial variability in outcomes across task-selection strategies. Using a simulation derived from real student interaction data, this study shows how certain learner decisions can systematically hinder mastery learning, while others align well with learning objectives.

5.1 Strategy Variability and Validation

Across both datasets, weakness-targeting strategies consistently produced efficient learning paths with minimal overpractice. In contrast, the risk-averse strategy that minimizes worst case loss, which tends to prioritize skills with already high estimated mastery, emerged as a clear outlier and resulted in substantially higher levels of overpractice. This pattern may be explained by the fact that stronger skills are closer to mastery and involve lower expected errors and mastery loss, leading the risk-averse strategy to favor already well-practiced skills and thereby induce redundant practice. Notably, this form of risk aversion has been documented in real learners and is therefore likely to generate meaningful differences in learning efficacy across students, depending on whether they exhibit this behavior [2]. Next we discuss how constraints on task-selection can mitigate these differences.

5.2 System Constraints Mitigate Inefficiencies

Our findings show that system constraints on task-selection are more effective when applied selectively. Task-selection and problem-selection constraints substantially reduced inefficiencies for the risk-averse strategy, bringing its performance to levels similar to those of other, more efficient strategies overall. At the same time, these constraints had little to no effect on strategies that were already efficient, such as Weakness Targeting or Interleaving. This asymmetry suggests that applying the same constraints to all learner types is unnecessary (and that student preferences for specific skills can be honored for some students more than others without sacrificing mastery efficiency). Instead, simulation enables identification of which learner behaviors warrant targeted system constraints, allowing system designers to intervene only where inefficiencies are likely to arise. Such selective constraint application aligns with common practice in ITS [12, 19], where system constraint is routinely adapted based on learner state rather than applied uniformly. An open question for future work is whether students would be able to recognize different levels of system constraints on task-selection (some being invisible to them but potentially felt during problem completion). Overly prominent system constraints may undermine student autonomy perceptions and thereby lower motivation, ultimately hindering learning [3]. However, because our constraints are designed to preserve shared control by bounding rather than removing learner choice, they are intended to mitigate inefficiencies while maintaining the motivational benefits associated with autonomy.

5.3 Equity and Shared Control

Prior work based on large-scale evidence has shown that students exhibit large differences in their level of engagement and persistence in various adaptive learning systems [11, 16]. Here, we turn to another, underinvestigated aspect of student outcomes in mastery learning: the impact of decision-making strategies when choosing tasks. While our findings suggest that constraining control may lead to more equitable benefits of mastery learning, it is also worth highlighting that there are benefits to student control, particularly with regards to the aforementioned persistence differences highlighted in prior work [11, 16]. In particular, past research notes motivational benefits of control related to engagement, motivation, and metacognitive development. By contrast, targeted system constraints offer a middle ground where preserving learner choice while mitigating extreme inefficiencies that disproportionately affect certain learners [8, 17, 20].

5.4 Simulation to Close the Loop

More broadly, this work contributes a novel framework and evidence of how simulations can support close-the-loop experimentation in educational data mining by serving as a bridge between data analysis and learning system redesign [12]. Grounded in real student interaction data and using standard EDM models such as AFM and BKT, our simulation enables systematic evaluation of how alternative design choices, specifically different levels of learner control and system constraints, shape learning efficiency prior to classroom deployment. This aligns with prior work on design-loop adaptivity, which emphasizes using data-driven analyses to inform and prioritize redesign decisions that can later be validated through in vivo experimentation [12]. We treat simulation as a complementary pre-deployment tool that reduces risk and helps identify which learner behaviors and system interventions warrant targeted classroom evaluation.

Additionally, the simulation was reproducible across datasets of student interaction data spanning different problem domains. Common anticipated trends—such as inefficiencies arising from risk-averse strategies—were consistently observed across both datasets. Notably, overpractice outcomes for equation-solving tasks exhibited greater variability than those observed in other domains. This finding aligns with the notion that equation-solving problems often admit multiple solution paths involving distinct underlying skills, in contrast to graph-interpretation tasks. Moreover, equation-solving problems frequently exhibit highly recursive structures with greater skill repetition, which may further contribute to the observed variability [23].

5.5 Limitation and Future Work

This study models a limited set of learner task-selection strategies and system constraints grounded in prior empirical work, and does not capture the full range of motivational, metacognitive, or affective factors that may influence learner behavior. Our simulation focuses on a task-selection-first setup and does not model alternative task-selection paradigms (e.g., direct problem-selection, multi-task-selection, or fully system-driven sequencing), though the framework could be extended to support these regimes. Learner strategies are modeled as static, whereas real learners adapt their strategies over time in response to feedback or outcomes. We leave the investigation of dynamic combinations of strategies to future work. Future work could also extend our framework by incorporating models of motivation and self-regulated learning to examine how different forms of shared control affect engagement and metacognitive processes. Finally, the simulation-based approach can inform iterative, close-the-loop system redesign by identifying promising constraint strategies prior to classroom de-

ployment and refining models using additional learner data across domains [12].

6. CONCLUSION

This study contributes a novel simulation-based educational data mining framework for examining how learner task-selection strategies and system constraints jointly shape mastery learning efficiency in ITS. Grounded in real student data and implemented using standard EDM models, our simulations reveal substantial variability in the efficiency of different learner task-selection strategies. In particular, while some strategies align with mastery learning objectives, others can lead to extreme inefficiencies in practice. Our results show that targeted system constraints can mitigate these inefficiencies without removing learner control, while having minimal impact on strategies that are already effective. This highlights the value of selectively deploying scaffolding mechanisms rather than adopting uniform control policies, and underscores the importance of accounting for learner strategy diversity in the design of adaptive learning systems. Broadly speaking, this study demonstrates how simulation can support close-the-loop data-driven redesign in educational data mining. By enabling systematic evaluation of alternative design choices prior to classroom deployment, simulation helps reduce risk, accelerate iteration, and prioritize which interventions merit further classroom testing. As learner-controlled systems become more widespread, these methods will be increasingly important for ensuring that the benefits of educational technology are distributed equitably without amplifying disparities in learning outcomes. Practically, this work suggests that ITS designers seeking to implement shared control should move toward selectively or adaptively applying constraints that target inefficient learner task-selection strategies. Our findings highlight the value of simulation as a low-cost and scalable tool for evaluating ITS design choices, enabling researchers to test and refine potentially inequitable or suboptimal interventions before deploying them in real learning environments.

ABSTRACT

Understanding student errors in the programming is a cornerstone of programming education, yet obtaining a representative set of student errors for any newly designed task remains slow and costly, since authentic submissions only accumulate after extensive classroom deployment. This paper explores whether large language models (LLMs) can serve as scalable proxies for students by simulating realistic logical errors in code submissions. Using the CodeWorkout dataset of 74,000+ unique student Java submissions across 37 problems, we evaluate five LLMs under three mainstream prompting strategies: Input-Output (IO), Chain-of-Thought (CoT), and iterative Self-Refine. We assess performance along two key dimensions: diversity (the range of distinct error patterns) and alignment (alignment with authentic student mistakes), and examine how these vary by struggling level of programming tasks. Our quantitative findings reveal that while all models generate diverse errors, their alignment to human submissions diverges: *Claude Sonnet 4* achieves the most balanced performance. In addition, we conducted a blinded expert annotation study ($N = 401$) comparing synthetic and authentic errors. This qualitative analysis confirms that the generated errors are functionally indistinguishable from authentic student errors. Moreover, higher-struggling-level problems elicit more diverse but less student-like errors. These results highlight trade-offs in using LLMs to simulate human learners and suggest design considerations for integrating synthetic errors into teachable agents, intelligent tutoring systems, and large-scale learning analytics.

1. INTRODUCTION

Programming education plays a foundational role in modern STEM curricula. Throughout this learning process, students inevitably make errors. Such errors not only expose students' weaknesses but also reveal their underlying cognitive processes—especially logical errors, which trace how learners reason about a problem. Unlike syntactic mistakes, logical errors are more subtle: they reflect learners' incomplete understandings, misconceptions, and flawed problem-solving strategies. For decades, capturing such errors has been a cornerstone of learner modeling, personalized feedback, and adaptive instructional support in computer science education [4, 25]. When teachers can foresee likely student errors, they can proactively design targeted scaffolds and address common pitfalls before they hinder student progress. Furthermore, integrating realistic error patterns into teachable agents can prompt learners to recognize and learn from these errors [19]. Yet, anticipating the full spectrum of plausible student solutions and their corresponding failure modes for different tasks remains difficult, especially for novice educators or system designer.

Recent advances in Large Language Models (LLMs) suggest a promising path forward. LLMs can serve as scalable proxies for learners[8, 32, 5, 9], generating realistic error datasets that can power personalized feedback systems, intelligent tutoring environments, and deeper investigations into novice cognitive processes [18]. More broadly, LLMs are increasingly positioned as versatile tools for simulating students in learning analytics. This includes modeling learning behaviors [23], enriching classroom analytics with simulated reasoning [32], and reflecting the collaborative and motivational dynamics of online learning environments [13].

Despite these advancements, the specific challenge of simulating *logical* errors in programming education remains largely underexplored [16], and current approaches sit at two unsatisfying extremes. On one end, general prompting of LLMs typically yields correct or near-perfect solutions, entirely missing the characteristic flaws inherent to novice code [29, 26]. On the other, random corruption strategies (e.g., inserting arbitrary bugs) produce artificial mistakes that lack the pedagogical value of errors emerging from genuine, flawed reasoning. The challenge is thus one of indistinguishability a generated error must be wrong in ways a real student

would be wrong—reflecting partial understandings, misconceptions, and incomplete problem-solving strategies rather than surface-level noise [21, 27]. Yet existing evaluation infrastructure offers little traction here. Programming benchmarks such as HumanEval, MBPP, and CodeContests are designed around absolute correctness, and recent work exploring synthetic buggy code has treated such code primarily as a vehicle for data augmentation [14] or focused on overall error distribution [16] rather than logical errors

To evaluate whether LLMs can simulate students' logical errors, two properties must hold simultaneously: the generated errors need (i) span a sufficiently diverse space of failure modes, and (ii) exhibit high alignment by aligning with the actual errors students produce. Moreover, both properties may depend significantly on the intrinsic difficulty of the programming task. Problems that elicit numerous repeated attempts likely surface qualitatively different, and more varied, patterns of novice reasoning than those solved on the first try. We therefore operationalize the *struggling level* of a problem using the total volume of student submissions as a behavioral proxy for empirical learning difficulty. Building on this perspective, we investigate how different combinations of models and prompting strategies influence the ability of LLMs to simulate student-like logical errors in programming. Specifically, we aim to answer the following research questions:

- **RQ1 (Diversity):** How do different LLMs and prompting techniques vary in generating a diverse and expansive set of erroneous code?
- **RQ2 (Alignment):** To what extent does LLM-generated erroneous code align with real student logical errors?
- **RQ3 (Struggling Level as a Moderator):** How does the struggling level of problems affect LLMs' performance in simulating student-like logical errors?

2. RELATED WORK

2.1 Student Errors in Programming

Errors are the most common byproduct of the students' learning process and serve as valuable learning resources. Teachers can analyze student errors to provide feedback and adjust their instructional plans, while students can engage in self-regulated learning through analyzing their own mistakes [34] or vicarious learning through erroneous examples [20]. In programming education, student errors have different types. Albrecht et al [2], examined 12,371 submissions from 280 students and identified six error categories: syntactic, conceptual, strategic, sloppiness, misinterpretation, and domain knowledge errors. According to other researchers, logic errors represent the primary challenge that programming education must address [25, 15]. Logic errors also encompass various subcategories. For instance, [7] analyzed 15,000 code fragments containing logic errors and classified them into algorithmic errors, misinterpretations of the problem, and fundamental misconceptions, finding that misconceptions are the most frequent source of logic errors. Other researchers have identified additional logic error types, such as loop condition errors and logical operator misuse [12]. By summarizing and analyzing these typical errors, valuable guidance can be provided for teachers' instruction, or as the error proxy for students when they interact with teachable agent.

2.2 LLM-Based Student Simulation

Researchers have begun designing specific prompts to enable LLMs to assume particular roles or generate content that aligns with role-specific characteristics, leading to the emergence of student simulation research [32, 24, 31, 5]. These studies encompass three main approaches: (1) direct agent simulation where LLMs embody virtual personas for flexible interactions, such as [33] trained models to simulate students' cognitive abilities using transaction data from tutoring systems, and [24] introduced TutorUp, a GPT-4-based platform enabling novice educators to practice engagement strategies through scenario-based interactions with simulated students; (2) teacher-student dialogue simulation, exemplified by [11] utilized GPT-4 and Claude-3.5 to enhance teaching plan quality by simulating teacher-student interactions and generating teaching reflections; (3) mimicking students' responses and behaviors, such as [31] build the students agent to respond to responsive teaching in teacher training. In the programming education domain, [16] conducted a comparative study examining bug distributions generated by GPT-4 versus those produced by students, finding that while unguided LLMs do not generate plausible error distributions, they can be guided to produce realistic error patterns when provided with descriptions of common errors and typical frequencies. However, despite this preliminary exploration of LLM-based student programming error simulation, several gaps remain: the study lacks comparison across different LLMs, does not focus specifically on logical errors, and fails to examine the diversity of generated errors.

3. METHODOLOGY

To investigate to what extent LLMs can simulate logical errors in programming, we designed and executed a multi-stage methodology, leveraging the CodeWorkout dataset and a suite of prompting strategies across several LLMs, which is summarized in Figure 1. The process begins with (1) Data Preparation phase, where we scrape, merge, and filter the CodeWorkout dataset to create a clean set of Java programming problems. Next, in the (2) LLM Error Simulation phase, each problem is presented to a suite of LLMs using three distinct, parallel prompting strategies: an IO Prompting, a CoT Prompting, and an iterative Self-Refine loop.

3.1 Dataset

We constructed our dataset from *CodeWorkout*, which provides detailed logs of students' programming submissions for introductory Java exercises. These data were collected from 410 undergraduate students in an introductory Java course at Virginia Tech during the Spring and Fall 2019 semesters [6]. The raw data includes problem descriptions, code snapshots, and error-labeled submissions et al. To prepare it for analysis, we developed a preprocessing pipeline (Figure 1) that transformed the raw logs into a clean, Java-focused corpus. Because large-scale CodeWorkout logs can contain abnormal or non-representative submissions (e.g., empty, duplicated, or otherwise anomalous traces), we follow prior work on detecting abnormal CodeWorkout submissions when considering data quality and filtering decisions

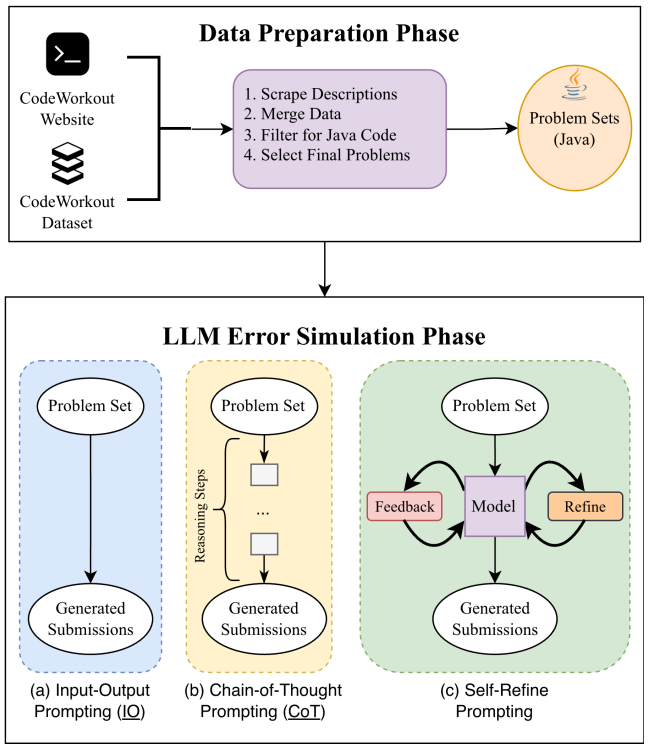

Figure 1: An overview of the experimental pipeline.

[10]. In addition, since the logs contained multiple programming languages, we applied a heuristic classifier based on regular expressions to identify Java submissions. Finally, to focus specifically on logical errors, we filtered out submissions that contained syntax errors (which fail to compile) and those that contained completely correct code. Consequently, the retained submissions consist exclusively of compilable yet incorrect code, ensuring the presence of logical errors. From the filtered corpus, we extracted the unique function names students were required to implement and aligned them with the scraped descriptions, ensuring all tasks used in our study were authentic CodeWorkout problems. The final dataset comprised 37 distinct Java problems. To capture variation in student struggle, we categorized them into three levels: Low (avg. 1,187 submissions), Medium (avg. 2,049) and High (avg. 4,125) based on the total number of student submissions per problem. Problems were sorted by submission count and evenly divided across levels (See detail in the Digital Appendix[1] D, Table 5).

3.2 Prompting Strategies

We compared three prompting strategies: Input-Output (IO), Chain-of-Thought (CoT), and iterative Self-Refine. *Input–Output prompting* is the standard direct-instruction baseline in which the model is given the task description and produces the final output in a single step, without articulating intermediate reasoning; it serves as the reference against which more elaborate strategies are compared [28]. *Chain-of-Thought prompting* [28] instructs the model to articulate intermediate reasoning before emitting the final answer; in our setting, the model first writes a one- to three-sentence rationale describing the intended logical slip and then produces the buggy code. *Self-Refine* [17] is an iterative framework in which the model generates an initial output, a critic instance produces structured feedback against a rubric, and a refiner instance rewrites items flagged for revision; this loop repeats for up to four iterations or terminates early when the critic judges the entire set compliant. Each strategy was implemented as a distinct prompting pathway in our pipeline (Figure 1), but all share the same experimental goal: generate multiple compilable Java submissions per problem, each containing exactly one non-trivial logical error and reflecting a plausible student attempt. The exact strategy instantiations, related prompts, and examples are documented in Digital Appendix A.

4. EXPERIMENTS

4.1 Experimental Setup

Our experiment was designed to compare the performance of different LLMs and prompting strategies in generating plausible, student-like programming errors for the 37 problems in our finalized dataset. As noted in the "LLM Error Simulation" phase of Figure 1, we employed a diverse set of LLMs, including `google/gemini-2.5-pro`, `openai/gpt-5`, `openai/gpt-4o`, `anthropic/claude-sonnet-4`, and `x-ai/grok-code-fast-1`. These models were selected based on their performance on programming and code generation tasks at the time of this study, as indicated by leading industry benchmarks including the Vellum AI LLM Leaderboard [2], LiveBench [3], and OpenRouter [4]. All code generation tasks were performed with a sampling temperature of 0.0 to minimize output variance. An exception to this temperature setting was the feedback step in the Self-Refine strategy, which used a temperature of 0.3 to encourage more descriptive critiques.

4.2 Data Analysis

4.2.1 Automated Metrics

For RQ1, we constructed abstract syntax trees (ASTs) for the generated erroneous code and computed pairwise edit distances using the Zhang–Shasha (ZSS) algorithm for each experimental condition [30]. Specifically, for each problem, we calculated the mean edit distance across the erroneous code samples, and then averaged these values across all problems. Larger distances indicate greater diversity in the generated erroneous code, meaning that within a given programming task, the more dissimilar the erroneous code samples are, the less consistent their error patterns become, thereby reflecting higher diversity.

For RQ2, to evaluate the alignment between LLM-generated and human erroneous code (fidelity), we first deduplicated student submissions, yielding 74,080 unique codes across 37 programming problems. Each LLM-generated erroneous code was then compared against human submissions for the

[1] `https://github.com/ErrorSimulEDM/Digital-Appendix/blob/main/DigitalAppendix_ErrorSimul.pdf`

[2] `https://www.vellum.ai/llm-leaderboard`

[3] `https://livebench.ai/`

[4] `https://openrouter.ai/rankings`

corresponding problems. Since exhaustive all-pairs comparison was computationally infeasible (on average 2,002 human codes per task), we employed a two-stage matching strategy. In Stage 1, we represented each code as a bag of tokens and used Jaccard similarity to retrieve the top-K most similar human codes for each LLM-generated submission ($K = 100$, i.e., Recall@100 retrieval). In Stage 2, we applied the Zhang–Shasha tree edit distance within this candidate set to identify the nearest human match for each LLM-generated code. We use the ZSS distance to the nearest human match as our structural alignment metric (lower values indicate closer alignment with authentic student errors).

For RQ3, to investigate the effect of the struggling level of a problem, we compared edit distances across three struggling levels to analyze how the struggling level of a problem moderates both the diversity of LLM-generated erroneous code and their alignment with authentic student erroneous code.

4.2.2 Qualitative Evaluation

While automated metrics provide a scalable measure of structural similarity, they do not fully capture the pedagogical utility of the generated errors. To address this limitation and to support construct validity, we conducted a qualitative study designed to assess whether the errors generated by the LLM are indistinguishable from authentic student errors to an expert instructor.

Study Design and Protocol. We employed a stratified sampling strategy to construct a balanced dataset of $N = 444$ code submissions across all 37 problems [3, 1]. For each problem we sampled 12 submissions (6 authentic from the CodeWorkout logs and 6 synthetic generated by our best-performing model, *Claude Sonnet 4* with Self-Refine), yielding $37 \times 12 = 444$ items. All submissions were stripped of source-identifying metadata before annotation.

Pilot Study and Codebook Development. Two authors first conducted a pilot study on a random subset of $N = 43$ submissions, double-coding each item independently. Through an iterative collaborative process, the annotators reconciled disagreements and established a consensus codebook [22] covering (i) eight logic-error categories with operational definitions and disambiguation rules (e.g., distinguishing Boundary errors from Condition Logic errors), and (ii) anchor descriptions for each level of the five-point plausibility scale, and (iii) whether the code was written by a Human Student or an LLM. The eight categories used in the final analysis (Table 4) were: *Condition Logic* (faulty boolean expressions in `if`/`while` conditions); *Boundary* (off-by-one and edge-case handling); *Concept* (misunderstanding of the problem requirements or intended algorithm); *Method* (incorrect use of library or built-in methods); *Infinite Loop* (non-terminating control flow); *Scope* (variable-scope or lifetime errors); *Type* (type-related faults, e.g., `==` vs `.equals`); and *Other* (a residual bucket for logical errors that did not map cleanly to a single named category, including strategy- or algorithm-level faults where the chosen approach itself is wrong, and, for authentic submissions, multi-fault or structurally awkward but compilable attempts).

Annotation Phase. The remaining $N = 401$ submissions (205 authentic, 196 synthetic) were divided between the two annotators, who each single-coded their assigned items under the finalized codebook with submissions blinded to source. Cases that the assigned annotator found ambiguous were brought to joint review and resolved by discussion. We did not compute a formal inter-rater reliability statistic on the main set because items were single-coded; the pilot phase served as the calibration step, after which the codebook was held fixed. The annotation criteria were:

(1). Source Attribution (Turing Test): A binary judgment on whether the code was written by a Human Student or an LLM. **(2). Plausibility Score:** A five-point Likert rating (1 = Highly Artificial, 5 = Highly Authentic) assessing whether the error reflects a genuine novice misconception. **(3). Logic Error Taxonomy:** Categorization of the primary functional fault into one of the eight categories above.

5. RESULTS

5.1 RQ1: Diversity

LLMs can generate diverse erroneous code, but vary on different models and prompt strategies. Overall, the results in Table 1 indicate that LLMs (across five models) are capable of producing diverse erroneous code, as reflected in the non-trivial mean edit distances observed across all models and prompting techniques. This suggests that, when prompted for multiple outputs on the same programming task, the generated code samples are not identical but vary in structure and content, thereby enabling the study of model-driven error diversity. However, some differences emerged both across models and across prompting strategies. At the model level, Gemini 2.5 Pro and Claude Sonnet 4 exhibited the largest average edit distance diversity, consistently exceeding 60 under most prompting techniques, indicating that they tend to generate more heterogeneous erroneous solutions. In contrast, GPT-4o demonstrated the smallest diversity, with mean edit distances around 25–40 depending on the prompt, suggesting more conservative or repetitive error patterns. GPT-5 and Grok Code Fast 1 occupied an intermediate position, with mean edit distances in the 40–60 range. Prompting strategies also modulated the diversity of erroneous outputs, though the effect was less uniform across models. For instance, in Claude Sonnet 4, the Self-Refine prompt reduced the mean edit distance compared to IO and CoT, suggesting more constrained revisions. By contrast, for Gemini 2.5 Pro, the CoT prompting increased variability, yielding the highest distance (72.55) observed in the dataset. Meanwhile, in models such as GPT-4o and Grok Code Fast 1, IO and Self-Refine performed comparably, with CoT prompting producing slightly higher diversity in some cases.

5.2 RQ2: Alignment

LLMs can simulate student erroneous code, but vary on different models and prompt strategies. We evaluated the alignment between LLM-generated erroneous code and human submissions by computing the mean of the nearest edit distance between each simulated code and its most similar human counterpart. Smaller distances indicate greater similarity to authentic student errors.

5.2.1 Structural Alignment (AST Analysis)

Table 1: Mean Edit Distance by Prompting Method and Model (values are mean ± SE).

	Models				
Method	*Claude Sonnet 4*	*GPT-4o*	*GPT-5*	*Gemini 2.5 Pro*	*Grok Code Fast 1*
IO	**63.33**±1.56	25.26±1.17	52.54±1.37	63.03±2.16	43.42±1.47
CoT	61.34±1.92	**39.93**±1.96	**60.28**±1.59	**72.55**±2.61	**54.94**±2.41
Self-Refine	46.89±2.02	25.97±1.33	59.97±2.10	59.28±1.83	44.43±2.18

As shown in Table 2, the results show that LLMs are capable of generating erroneous code that resembles student submissions (the nearest edit distance is 16.35), but the alignment of this simulation depends on the choice of model and prompting strategy. The distances are never negligible, meaning the simulation is not perfect, yet some models produce errors strikingly close to those made by students. Claude Sonnet 4 provides the most consistent alignment: across all prompting strategies, its distances remain relatively low, with the best case (16.35 under Self-refine) being the closest match to real student code among all conditions. Grok Code Fast 1 also demonstrates strong potential, achieving the absolute minimum distance (16.22) with Self-Refine. However, its performance fluctuates more across prompts (rising above 30 under IO and CoT), showing that while Grok can mimic student errors well, this depends more on the prompting technique. By contrast, GPT-5 and Gemini 2.5 Pro exhibit much larger distances, often exceeding 80, suggesting that although they generate erroneous code, the errors diverge considerably from authentic student patterns. GPT-4o lies in between: sometimes close to students (20.41 with CoT) but inconsistent, particularly when Self-Refine is used. Prompting strategies influence these outcomes. CoT generally improves alignment, especially for Claude and GPT-4o. Self-Refine has mixed effects: it delivers Grok's best result but worsens GPT-4o's alignment.

5.2.2 Human Evaluation

(1). Source attribution. For source attribution, we report the deception rate: the proportion of LLM-generated submission that annotators misclassified as human-written. By construction, this metric is defined only on the 196 synthetic items. Annotators misclassified 164/196 (**83.7**%) of LLM-generated submissions as human-written, indicating a low level of distinguishability.

(2). Plausibility score: Contrary to the expectation that synthetic errors might be noisier or less coherent, the LLM-generated submissions received a significantly higher mean plausibility score ($M = 4.27, SD = 1.07$) than authentic student errors ($M = 3.78, SD = 1.11$). A Mann-Whitney U test confirmed this difference is statistically significant ($p < 0.001$).

This counterintuitive pattern is explained by the differences in shape between the two error distributions (Table 4). LLM-generated submissions concentrate on clean, single-purpose logical bugs, Condition Logic (46.4%) and Boundary (21.9%) faults dominate, which annotators read as canonical, textbook-style misconceptions. Authentic student code, although pre-filtered for compilability, exhibits a broader and more diffuse distribution: a residual 28.3% of submissions fell into the *Other* category, which captured logical errors that did not map cleanly to a single named type, including strategy- or algorithm-level faults and multi-fault attempts where several slips co-occurred in the same submission. Because the plausibility scale rewarded errors that read as a single, identifiable misconception, the LLM's narrower, well-formed bug distribution scored higher than the more diffuse one in authentic submissions. In practice, the LLM behaves like an idealized novice, valuable for isolating individual misconceptions when training intelligent tutoring systems, but a less faithful proxy for the full messiness of authentic student work.

5.3 RQ3: Struggling Level as a Moderator

LLMs simulate better in low-level questions but have higher diversity in high-level questions. As shown in Figure 2, mean edit distances among LLM submissions increased substantially from low- to medium-struggling problems, and remained high at high-struggling problems for most models. This indicates that harder problems elicited more heterogeneous erroneous outputs, consistent with the expectation that higher-struggling problems open up more possible failure paths. For example, Gemini 2.5 Pro (CoT) rose from 62.34 (low) to 82.89 (medium) and stayed high at 74.59 (high). To probe the diversity of simulated errors, we conducted a case-level analysis using the best-performing setting (Gemini 2.5 Pro with CoT). For each coding problem, we measured the mean pairwise edit distance among all generated erroneous submissions. The results reveal strong problem-specific variation. For example, for problem "sortasum" (mean distance = 8.00), the model repeatedly produced nearly identical error patterns, with minimal structural variation. By contrast, in "fix45" (mean distance = 211.17), the generated errors were far more heterogeneous, with edit distances ranging from near zero to above 250. Heatmaps (Figure 3) illustrate these two representative cases. Additional code examples for both problems are provided in Digital Appendix H.

Alignment of LLM-generated code (simulated–human). Figure 4 illustrates how the struggling level of coding problems affects the similarity between LLM-generated erroneous code and authentic student submissions. Overall, we observe a clear trend: as the level of struggle increases, the mean nearest edit distance also increases, indicating that LLMs find it harder to reproduce student-like logical errors on higher-struggle problems. Across models, Claude Sonnet 4 demonstrates the most stable performance, maintaining relatively low distances across all levels, but still has a slightly longer distance as the struggling level increases. Moreover, other models, such as GPT-5 and Gemini 2.5 Pro, show substantial increases in distance at medium and high levels, indicating that their simulated errors diverge further from authentic student behavior as the struggling level rises.

Table 2: Mean Nearest Edit Distance by Method and Model (values are mean ± SE).

Method	Models				
	Claude Sonnet 4	*GPT-4o*	*GPT-5*	*Gemini 2.5 Pro*	*Grok Code Fast 1*
IO	22.48±1.80	34.30±2.70	93.75±2.46	**56.66**±3.85	39.66±3.06
CoT	24.94±2.22	**20.41**±2.15	100.56±2.47	87.44±3.48	33.54±3.07
Self-Refine	**16.35**±1.80	49.85±3.08	**80.59**±3.47	82.01±3.16	**16.22**±1.78

6. DISCUSSION AND CONCLUSION

This study investigated whether LLMs can simulate student-like logical errors in programming tasks and under what conditions. We identified two key dimensions, diversity and alignment, as central to their usefulness as proxies for authentic errors. On diversity, all models produced varied erroneous code, though to different extents: Gemini 2.5 Pro and Claude Sonnet 4 showed the broadest diversity (especially with CoT prompting), whereas GPT-4o generated more homogeneous patterns. On alignment (fidelity), i.e., resemblance to authentic erroneous code, Claude Sonnet 4, GPT-4o, and Grok Code Fast 1 aligned most closely with real submissions (notably with Self-Refine prompting), while GPT-5 and Gemini 2.5 Pro diverged more substantially. These trade-offs are illustrated in Figure 5: models strong in diversity (e.g., Gemini) often exhibit weaker alignment, and vice versa, with Claude Sonnet 4 standing out as the most balanced option. Yet even Claude's performance varied across tasks and prompts, underscoring that no single LLM is universally optimal. These findings suggest that model choice should be guided by analytic goals: diversity-oriented models can help explore the breadth of potential misconceptions, while alignment-oriented models are better suited for approximating authentic error distributions.

In addition, our results suggest that the coding problem-struggling level plays a dual role (also see Figure 5): while a higher struggling level increases diversity of simulated errors, expanding the coverage of potential failure modes, it simultaneously reduces alignment between simulated and authentic code, suggesting that while models generate a wide variety of errors, these may diverge from the authentic patterns observed in learners. This duality highlights the importance of considering both diversity and fidelity when utilizing LLMs as proxies for student error data generation and analysis: models may excel at producing diverse erroneous code for higher-struggling tasks, but not all of those errors are truly representative of human misconceptions. Beyond the immediate evaluation of LLMs as error simulators, our findings intersect with ongoing discussions in learning analytics. In practical deployments, these diversity–fidelity trade-offs can be used to tune synthetic error generation toward either broad misconception coverage or closer approximation of observed classroom error distributions. The capacity of LLMs to generate diverse yet realistic errors offers a potential avenue for augmenting student data, particularly in contexts where authentic data is scarce, sensitive, or difficult to collect.

Finally, simulating students' programming errors using LLMs holds significant pedagogical value, particularly in address-

Table 4: Distribution of Error Types: Human students vs. LLM-generated.

Source	Condition	Boundary	Concept	Method	Infinite	Scope	Type	Other
Human students	**24.9%**	12.2%	14.6%	9.3%	1.5%	5.4%	3.9%	28.3%
LLM-generated	**46.4%**	**21.9%**	16.8%	5.6%	0.5%	0.0%	0.5%	7.1%

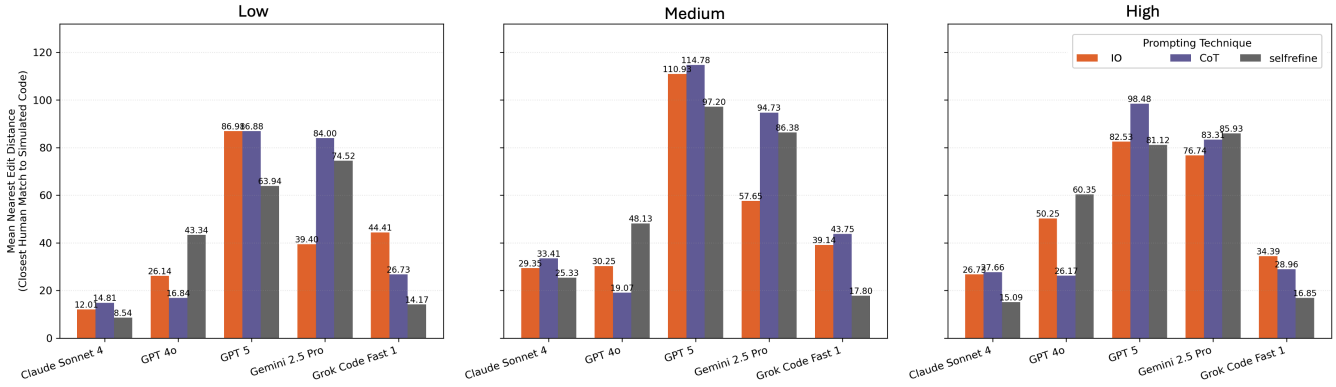

Figure 4: Mean Nearest Edit Distance Between LLM-Generated and Human Code Errors Across Tasks of Different Struggling Levels

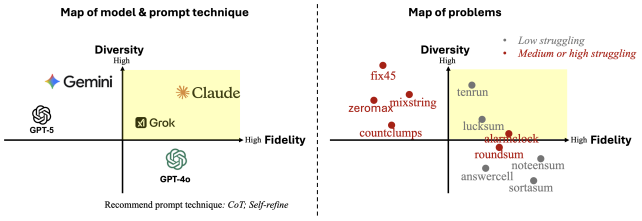

Figure 5: Trade-offs Between Alignment (fidelity) and Diversity in LLM-Simulated Student Errors

ing the challenge of data scarcity in educational technology. First and foremost, large-scale synthetic error datasets can be leveraged to train and evaluate automated tutoring systems (AI Tutors). This allows intelligent systems to better diagnose and provide feedback on diverse, realistic student misconceptions without being constrained by the limited availability of human-generated data. Second, from a student-centric perspective, these generated errors can be integrated into "teachable agent" environments. By tasking learners with diagnosing and correcting mistakes made by an AI proxy, the system fosters vicarious learning and deepens students' metacognitive debugging skills. Lastly, while it is impractical for educators to manually review thousands of synthetic code snippets, curated subsets of these LLM-generated errors can still serve as valuable resources for teacher professional development [31]. Exposure to a concentrated variety of anticipated misconceptions allows teachers to practice formulating effective pedagogical responses and design more targeted instructional strategies prior to actual instruction [11].

Despite these promising results, several limitations should be considered when interpreting our findings. Our experiments are grounded in CodeWorkout and a curated set of 37 introductory Java problems, so the observed diversity-alignment = trade-offs may not generalize to other institutions, curricula, assessment formats, or programming languages. We operationalized struggling level as the total number of submissions per problem, which is a scalable proxy but may conflate difficulty with other factors (e.g., assignment placement, popularity, or course policies); alternative measures, such as error rates, time-to-correct, or concept difficulty models, could yield different patterns. Furthermore, our generation constraints (compilable code with exactly one non-trivial logical error) intentionally reduce syntactic noise and multi-fault behaviors common in authentic novice submissions, potentially producing an "idealized learner" distribution that is useful for isolating misconceptions but less representative of messy real-world student work; future studies should extend evaluation across broader datasets, richer difficulty measures, and semantic metrics. Finally, while the AST edit distance serves as a robust quantitative proxy for measuring structural variation, we acknowledge its inherent limitations. First, raw numerical distances can lack direct interpretability context across different programming tasks. Second, as a purely structural metric, it fails to fully capture semantic diversity; functionally equivalent codes may exhibit distinct AST structures, and vice versa. Future research should consider employing normalized metrics alongside execution-based semantic evaluations (e.g., test-case execution traces) to provide a more holistic assessment of error diversity.

ABSTRACT

Social learning networks (SLNs) are graphical representations that capture student interactions within educational settings (e.g., a classroom), with nodes representing students and edges denoting interactions. Accurately predicting future interactions in these networks (i.e., link prediction) is crucial for enabling effective collaborative learning, supporting timely instructional interventions, and informing the design of effective group-based learning activities. However, traditional link prediction approaches are typically tuned to general online social networks (OSNs), often overlooking the complex, non-Euclidean, and dynamically evolving structure of SLNs, thus limiting their effectiveness in educational settings. In this work, we propose a graph neural network (GNN) framework that jointly considers the temporal evolution within classrooms and spatial aggregation across classrooms to perform link prediction in SLNs. Specifically, we analyze link prediction performance of GNNs over the SLNs of four distinct classrooms across their (i) temporal evolutions (varying time instances), (ii) spatial aggregations (joint SLN analysis), and (iii) varying spatial aggregations at varying temporal evolutions throughout the course. Our results indicate statistically significant performance improvements in the prediction of future links as the courses progress temporally. Aggregating SLNs from multiple classrooms generally enhances model performance as well, especially in sparser datasets. Moreover, we find that jointly leveraging both the temporal evolution and spatial aggregation of SLNs significantly outperforms conventional baseline approaches that analyze classrooms in isolation. Our findings demonstrate the efficacy of educationally meaningful link predictions, with direct implications for early-course decision-making and scalable learning analytics in and across classroom settings.

1. INTRODUCTION

Collaborative learning is a major pillar of modern education, shaping student engagement, persistence, and academic success. Consequently, instructors increasingly incorporate structured peer interactions, such as peer instruction and discussion forums, to enhance learning outcomes [1, 3]. Yet, in practice, collaborative behaviors do not emerge uniformly across students or over time: some students rapidly become socially central, while others remain weakly connected or isolated, particularly in the early stages of a course. These uneven and evolving interaction patterns complicate instructors' ability to anticipate collaboration dynamics and intervene effectively when support is most needed.

In order to model and analyze such interaction dynamics, social learning networks (SLNs) have emerged as a powerful abstraction. SLNs represent classroom interactions as graphs, where *nodes* correspond to students and *edges* denote interactions arising from discussions, question–answer exchanges, or collaborative activities [12, 22]. This abstraction enables a principled investigation of network inference problems in educational graphs, with *link prediction* (i.e., forecasting which student interactions are likely to form in the future) serving as one of the fundamental problems in this setting.

1.1 Challenges and Motivations

Within SLNs, *link prediction* has emerged as a valuable tool for forecasting future collaborations, identifying at-risk students, and informing instructional interventions. Furthermore, accurate link prediction can reveal relationships between students' behavioral characteristics and their tendencies toward class involvement, which is often linked to their learning performance [29]. However, prior work on link prediction in educational settings has largely focused on analyzing each classroom independently, treating the SLN associated with a single course offering as an isolated graph [20, 30]. While this approach is intuitive, it implicitly assumes that meaningful structure must be learned anew for every classroom, ignoring common patterns of social and pedagogical dynamics that recur across courses, instructors, and academic terms. In addition, this approach fails to capture the temporal processes through which collaborations form early in the course when few observed links have been formed (i.e., the cold-start problem), thus preventing accurate link prediction precisely when early intervention would be most beneficial. Moreover, the inherent complexity of SLNs, including their evolving topology and irregular non-Euclidean

structure, renders traditional data-driven models [19] [27], such as convolutional neural networks (CNNs), ill-equipped for the task of link prediction.

Graph Neural Networks (GNNs), on the other hand, offer a powerful alternative to traditional CNNs when it comes to predicting links in SLNs. Unlike CNNs, which are primarily designed for grid-like data such as images, GNNs are tailored for irregular graph structures. This makes them particularly well-suited for SLNs, where nodes (students) and edges (interactions) form complex non-Euclidean structures [5]. Despite their potential, the application of GNNs in SLNs remains in its early stages, with only a handful of studies exploring their potential and limitations [20].

To address this gap in the literature, *our work leverages GNNs to unlock two critical domains in link prediction for SLNs: the 'temporal' domain and the 'spatial' domain.* Specifically, in the temporal domain, we examine the evolution of SLN graphs over time, while in the spatial domain, we investigate the effects of combining SLN graphs from different classroom contexts to improve link prediction performance equitably across classrooms.

1.1.1 Exploring the Temporal Domain

SLNs are inherently dynamic: the topology of these networks evolves as student interactions change throughout the course. This temporal evolution can significantly affect GNNs' future link prediction performance in SLNs. By analyzing how SLN structures shift at different stages of a course, we can uncover deeper insights into student interactions and the conditions under which link prediction performs best. We subsequently present and investigate, for the first time in the literature, the following hypothesis:

Hypothesis 1: *Do SLNs' temporal structures have a significant impact on the prediction capability of GNNs trained on them? If yes/no, how do link prediction performance metrics vary during the temporal evolution of SLNs?*

1.1.2 Investigating the Spatial Domain

Our study on the spatial domain of SLNs introduces the combination of SLN graphs across different classrooms. At first glance, merging SLNs might seem to improve model performance by providing more data. However, our intuition suggests that the unique topological structures inherent in each SLN, stemming from varied interaction patterns among peers in different classrooms, can lead to unexpected outcomes. Subsequently, our formally proposed hypothesis that we investigate for the first time in the literature is as follows:

Hypothesis 2: *Does combining SLNs together lead to better performance of the GNN models trained on them? If yes/no, how do link prediction performance metrics vary upon combining SLNs?*

1.1.3 Spatiotemporal Analysis

A careful observation of the interrelations between the temporal and spatial domains reveals non-trivial interactions. For instance, our intuition may suggest that combining SLNs at earlier stages of a course might be more beneficial, as networks are still forming and less defined. However, as SLNs develop their distinct patterns later in the course, merging them might not yield the same performance improvements. To encapsulate this nuanced view, we propose and investigate the following hypothesis:

Hypothesis 3: *Does combining SLNs together at different time stamps during a course lead to varying performance of the GNN models trained on them? If yes/no, how do link prediction performance metrics vary during the combination of SLNs at different time stamps of a course?*

1.2 Overview and Summary of Contributions

Formally, our contributions can be summarized as follows:

- We pioneer an investigation into the temporal evolution and spatial aggregation of SLNs by analyzing how link formation and interaction patterns change throughout a class and how classrooms can benefit one another through sharing their data. Our time-evolving analysis over multiple classroom SLNs provides novel insights into these dynamics.
- We develop a GNN-based framework designed to tackle the unique challenges presented by sparse, imbalanced, and temporally evolving SLN datasets. This framework is optimized to capture the complex topological features inherent in SLNs. We then use this framework to validate our ***Hypothesis 1***.
- We demonstrate that combining data from multiple SLNs, spanning different classroom contexts, can enhance link prediction performance under certain conditions. This contribution is focused on validating our ***Hypothesis 2***.
- By examining the interplay between the temporal evolution and spatial data aggregation of SLNs, we uncover non-trivial interactions that influence overall link prediction accuracy. This integrated analysis addresses our ***Hypothesis 3***, where our findings offer a refined understanding of how temporal and spatial factors collectively inform link prediction strategies.

2. RELATED WORK

Link prediction in general computational graphs (i.e., non-SLN graphs such as Online Social Networks (OSNs)) has evolved through various methodologies over time. Early methods relied on deriving features from the graph topology [15, 17] to infer future trends [13, 31]. While effective in some cases, these heuristic-based methods often fail to capture the inherent complexities of dynamic, rapidly-evolving graphs. To address these limitations, more rigorous link prediction approaches were developed, such as matrix factorization and probabilistic models, which aim to learn low-dimensional representations of nodes [11], [26], [18], [33]. Although these models yielded improved prediction accuracy, later methods further advanced performance by offering greater scalability and adaptability to capture the complex, evolving nature of OSNs. In particular, the advent of feature-based deep learning introduced models based on artificial neural networks for link prediction, which leverage node characteristics and graph adjacency information to improve link prediction in both general OSNs [8, 16, 24, 32] as well as SLNs [7, 20, 30]. While these methods achieved notable success, they typically treat graphs as static structures and lack the capability to effectively capture the temporal dynamics inherent in SLNs. Moreover, they fail to account for

the intricate topological structures and co-temporal evolution of interactions across multiple classrooms, limiting their applicability in educational settings.

More recently, GNNs have emerged as powerful tools for link prediction in general graph structures due to their ability to learn both the local structure and the global topology of a graph [2,4,9,14,21,23,28]. GNN-based models, such as Graph Convolutional Networks (GCNs) [10], GraphSAGE [6], and Graph Attention Networks (GATs) [25], have demonstrated superior performance compared to feature-based deep learning models by aggregating neighborhood information through learned message-passing schemes among nodes. Despite these advancements, no prior work has specifically examined GNN-based link prediction approaches in dynamically evolving SLNs, thus overlooking the temporal evolution and spatial aggregation properties that are unique to SLNs. As a result, the impact of SLN dynamics over time, the integration of information across classroom contexts, and the interplay between these two dimensions remain largely unexplored. Our work aims to address this critical gap in the literature.

3. METHODOLOGY

In this section, we begin by describing the mathematical representation of SLNs as graphs (Sec. 3.1). Next, we outline the task of link prediction in SLNs, detailing how GNNs are used to infer future links (Sec. 3.2). We then introduce our joint classroom approach, detailing the integration of SLNs to improve predictive performance in individual classrooms (Sec. 3.3). Lastly, we describe the evaluation metrics used to assess the link prediction performance (Sec. 3.4).

3.1 Representation of SLNs as Graphs

We represent each SLN as a graph $G = (\mathcal{V}, \mathcal{E})$, where $\mathcal{V}$ denotes the set of *nodes* (i.e., students) and $\mathcal{E}$ represents the set of *edges* (i.e., interactions between students). Each edge $e_{ij} \in \mathcal{E}$ signifies an interaction between two nodes/students v_i and v_j, where $v_i, v_j \in \mathcal{V}$, such as collaborative projects, discussions, or information exchanges. Subsequently, we define the adjacency matrix of the SLN graph as $\mathbf{A} = [A_{ij}]_{v_i, v_j \in \mathcal{V}}$, where

$$A_{ij} = \begin{cases} 1, & \text{if } (v_i, v_j) \in \mathcal{E} \\ 0, & \text{otherwise.} \end{cases} \quad (1)$$

In words, A_{ij} represents the presence ($A_{ij} = 1$) or absence ($A_{ij} = 0$) of a connection/edge between nodes v_i and v_j.

3.2 Link Prediction in SLNs

The temporal evolution of an SLN is illustrated in Fig. 1, showcasing a simplified example of an SLN across three sequential stages of a course. Subsequently, given the SLN graph described in Sec. 3.1 at some point t during the duration of a course/class (e.g., week 4 of the semester), our objective is to predict which links will form at a future time $t+t_0$ (e.g., week 6) between students by using GNNs. To this end, we adopt GraphSAGE [6], which learns node embeddings/features by iteratively aggregating information from local neighborhoods. As new nodes are not introduced in the SLN, this inductive learning approach enables the model to dynamically adapt node embeddings as local structures (i.e., student interaction patterns) evolve over time, making it well-suited for the temporal changes of student interactions throughout the course.

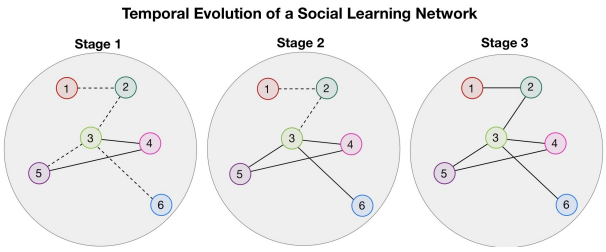

Figure 1: Visualization of SLN temporal evolution. Left to right shows the progress of the classroom from the beginning to the end. A solid line denotes an existing edge at that stage, and a dotted line denotes a non-existing edge at that stage that will become an existing one in a future stage.

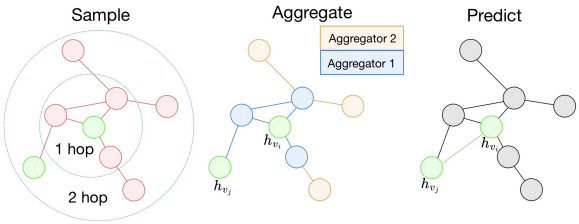

Figure 2: An overview of the GraphSAGE pipeline for link prediction. Left: Sampling stage, where the 1-hop and 2-hop neighborhoods of the target nodes (highlighted in green) are collected. Middle: Aggregation stage, where each node's embedding is updated by aggregating the features of its neighbors using multiple layers of aggregation (in our case, mean aggregator). Right: Prediction stage, where a dot product is computed between the final embeddings of the two target nodes to predict the existence of a link.

3.2.1 *Link Predictions based on GNNs in a Nutshell*

In a nutshell, to predict whether an interaction (i.e., a link) will form between two students v_i and v_j, we compute a numerical representation (embedding) for each student using a GraphSAGE model as we will later discuss (see Sec. 3.2.2). These embeddings capture the structural context of each student within the SLN. The likelihood of a future interaction is then estimated by taking the dot product of the respective node embeddings (potentially after propagating through one or more hidden layer) as follows:

$$\hat{y}_{v_i, v_j} = \sigma(h_{v_i}^\top h_{v_j}), \quad (2)$$

where $\sigma(\cdot)$ is the sigmoid function, h_{v_i} and h_{v_j} are the learned embeddings for students v_i and v_j, respectively ($h_{v_i}, h_{v_j} \in \mathbb{R}^d$), and $\hat{y}_{v_i, v_j} \in \mathbb{R}$.

3.2.2 *Obtaining Node Embeddings via GNN*

To obtain the node embeddings, we use a *two-layer GraphSAGE model*, where each layer aggregates information from a student's neighbors in the SLN. This model, depicted in Fig. 2, replicates a convolutional filter that is capable of operating in a non-Euclidean space (i.e., graph topology). Intuitively, at each SAGEConv layer, GraphSAGE updates the representation of a node by combining its own features with the aggregated features of its neighbors. By the second layer, the embedding of a node reflects not only its own character-

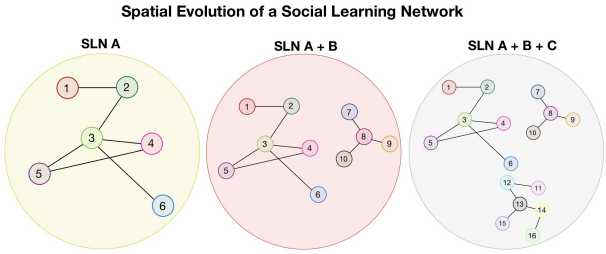

Figure 3: Visualization of spatial evolution. The left displays a single SLN A (representing a single classroom), the middle is SLN A combined with SLN B (i.e., two classrooms combined together), and the right is SLN A and B combined with SLN C (i.e., three classrooms combined together).

istics but also the structure and features of its broader local neighborhood, enabling the model to better infer potential future connections among nodes. In particular, the model begins with an input feature matrix $\mathbf{X} = [x_{v_i}]_{v_i \in \mathcal{V}} \in \mathbb{R}^{|\mathcal{V}| \times F}$, where the i^{th} row (i.e., $x_{v_i} \in \mathbb{R}^F$) corresponds to the feature vector of student v_i consisting of F features. Since our SLNs do not contain explicit node features (e.g., profile or grade data), each student is initialized with a unique trainable embedding vector. These initial embeddings are then refined through neighbor aggregation as follows.[1]

In the first layer, the model updates each student's embedding by averaging its own feature vector with those of its directly connected peers (1-hop neighbors). This step captures local interaction patterns through the following embedding:

$$h_{v_i}^{(1)} = \zeta\Big(W_1 \cdot \text{MEAN}\left(\{x_{v_j} | v_j \in \mathcal{N}(v_i) \cup \{v_i\}\}\right) + b_1\Big), \quad (3)$$

where $\zeta(\cdot)$ is the activation function, $h_{v_i}^{(1)} \in \mathbb{R}^{d_1}$ is the updated embedding for student v_i after one round of aggregation, $\mathcal{N}(v_i)$ is the set of students directly connected to v_i in the SLN (i.e., students who have interacted with v_i), $x_{v_j} \in \mathbb{R}^F$ is the feature vector of student v_j, W_1 and b_1 are trainable weights and bias parameters, and MEAN$(\cdot)$ takes the element-wise average across the set.

In the second layer, the model does the same aggregation, except this time, it uses the embedding from the first layer, allowing to implicitly capture information from 2-hop neighbors. In particular, the second layer of the model captures the following embedding:

$$h_{v_i}^{(2)} = \zeta\left(W_2 \cdot \text{MEAN}\left(\{h_{v_j}^{(1)} | v_j \in \mathcal{N}(v_i) \cup \{v_i\}\}\right) + b_2\right), \quad (4)$$

where $h_{v_i}^{(2)}$ is the final embedding for student v_i (i.e., used as h_{v_i} in (2)), and W_2 and b_2 are trainable parameters.

3.3 Classroom Merging and GNN Training

3.3.1 Merging Classrooms

To assess the impact of training a GNN for link prediction, we conduct experiments on individual and joint SLNs, capturing their spatial evolution. In particular, initially, we train separate GNN models for each classroom, using the same time instances of the SLN graph across the classrooms to ensure consistency across experiments. We then construct combined SLN graphs by merging classroom SLNs, systematically evaluating the combination of multiple classroom SLNs into a single joint graph. Subsequently, we train GNNs on these combined SLNs and evaluate their performance on individual classrooms to verify the impact of classroom combination on the link prediction performance of the trained models. We visualize the spatial aggregation of SLNs in Fig. 3.

3.3.2 GNN Training

To train GNNs over our SLNs (either on isolated or merged classrooms), we first note that there is an extreme class imbalance inherent in SLNs. This imbalance arises because *SLNs are sparse graphs*: the vast majority of possible node pairs in the graph do not share an edge, meaning that most students do not interact with each other.

To mitigate this imbalance during training, we use a weighted binary cross-entropy loss: for a predicted link score s of a given node pair and the respective ground truth label $y \in \{0, 1\}$ (1 for edge, 0 for non-edge), the loss is defined as:

$$\ell(s, y) = \begin{cases} \text{PCW} \cdot \log\left(1 + e^{-s^+}\right), & \text{if } y = 1, \\ \log\left(1 + e^{s^-}\right), & \text{if } y = 0. \end{cases}$$

The total loss across a positive and negative sample pair is:

$$\mathcal{L} = \text{PCW} \cdot \log\left(1 + e^{-s^+}\right) + \log\left(1 + e^{s^-}\right),$$

where s^+ and s^- denote the scores for a positive (i.e., connected) and negative (i.e., not connected) student pair, respectively. We found through a grid search, optimizing for the minimization of false negatives, that fixing *positive class weight* PCW $= 20$ provides a stable and effective training regime across all SLNs, balancing the impact of class imbalance without over-amplifying the minority class loss.

3.4 Evaluation Metrics

Although accuracy is a conventional metric for classification tasks, it is not appropriate in link prediction due to the large class-imbalance, where a model with relatively high accuracy may fail to predict any edges. Instead, we use the *Area Under the receiver operating characteristic Curve (AUC)*, as it provides a robust measure of predictive effectiveness in class-imbalanced settings since it evaluates a model's ability to rank positive samples (i.e., student pairs with edges) higher than negative ones, making it a more reliable indicator of performance in sparse graphs. The AUC is computed by

$$\text{AUC} = \frac{1}{|\mathcal{P}||\mathcal{N}|} \sum_{(s^+, s^-) \in (\mathcal{P}, \mathcal{N})} \mathbb{I}(s^+ > s^-), \quad (5)$$

where $\mathcal{P}$ and $\mathcal{N}$ denote the sets of predicted scores for positive and negative samples, respectively, and $\mathbb{I}(\cdot)$ is an indicator function that returns 1 if the positive score s^+ is greater than the negative score s^-, and 0 otherwise. In our context, the model assigns a score to each link (i.e., a student pair), where a higher score indicates a higher likelihood that the link should exist and a threshold score of 0.5 is used to determine the prediction of a link.

[1]Fig. 2 illustrates GraphSAGE assuming aggregation over all neighbors for clarity. However, in practice, GraphSAGE samples a fixed-size subset of neighbors at each layer to reduce computational overhead and memory usage.

Table 1: Metrics for each considered dataset including the number of nodes, edges, duration (weeks), and posts.

Dataset	# Nodes	# Edges	Duration	# Posts
VS	677	4702	5	7484
ML	3290	30610	12	25481
AL	1165	6773	13	16276
CP	900	3418	8	8255

4. RESULTS AND DISCUSSION

Henceforth, we discuss our empirical setup (Sec. 4.1) followed by analyzing our results in temporal (Sec. 4.2), spatial (Sec. 4.3), and spatiotemporal settings (Sec. 4.4). The code used in this work is available at `https://github.com/AliMohammadiasl/GNNs-for-SLNs`.

4.1 Empirical Setup

For our empirical analysis, we employ four SLNs collected from four distinct Massive Open Online Course (MOOC) datasets: Virtual Shakespeare (VS), Machine Learning (ML), Algorithms (AL), and English Composition (CP). The SLN data we used was introduced in [30] and captures structured interactions that occurred between students on discussion forums. Specifically, if student v_i and v_j interact on a discussion forum by posting an answer or a follow-up question to an initial post, we consider $A_{ij} = 1$. Our considered datasets intentionally span both STEM and humanities courses so that the efficacy of our approach can be evaluated across various disciplines. Tab. 1 summarizes these datasets.

Our GraphSAGE model consists of an $F = 16$-dimensional embedding for each node at the input followed by two convolutional layers. We use Rectified Linear Unit (ReLU) as the activation function following both hidden layers. For training, we perform full-graph updates for a total of 1500 epochs, optimizing the model with the Adam optimizer at a learning rate of $5e-4$ using the above-described weighted binary-cross entropy loss function.

To ensure robustness (in terms of the time that the model is used during the term/semester), we evaluate our models in multiple temporal snapshots of the SLNs. We define progress as the percentage of the term that has elapsed, with 0% representing the start and 100% the end. We consider 25%, 50%, 75%, and 90% progress, and we perform temporal k-fold cross-validation (with $k = 10$) and report the average AUC across all partitions for statistical validation.

4.2 Temporal Graph Analysis

We begin by examining how link prediction in SLNs evolve temporally throughout the duration of a single course (addressing **Hypothesis 1** from Sec. 1). Inspecting Tab. 2 and focusing on isolated GNN training (i.e., 'GNN iso'), which represents GNNs trained on a particular course in isolation, we observe consistent AUC improvements as more temporal data become available in each course. As expected, the AUC improves steadily as the course progresses, and the model benefits from richer structural information in later stages, particularly for smaller courses (e.g., VS, AL, and CP), which suffer from link formation data early on, than larger ones (ML). This indicates that the model becomes increasingly capable of distinguishing between likely and unlikely links between students as it observes more interactions. These trends indicate that temporal progress has a measurable impact on model performance, affirming **Hypothesis 1** from Sec. 1. Overall, later snapshots provide more robustness for learning, while early-course graphs pose prediction challenges due to the limited structural context.

Table 2: AUC performance of each considered model across four stages of course progress (25%, 50%, 75%, 90%). Temporal trends can be observed across progress stages of each course, while spatial effects are seen by comparing 'GNN iso' and 'GNN all' at each progress stage.

Dataset	Progress	GNN all	GNN iso	GCN [10]	GAT [25]	CNN [20]
VS	25%	**0.88**	0.86	0.82	0.87	0.64
VS	50%	**0.92**	0.89	0.85	0.89	0.62
VS	75%	**0.94**	0.88	0.86	0.90	0.60
VS	90%	**0.94**	0.88	0.85	0.89	0.67
ML	25%	**0.85**	0.84	0.76	0.82	0.72
ML	50%	**0.86**	0.85	0.70	0.83	0.83
ML	75%	0.86	0.84	0.69	0.83	**0.90**
ML	90%	**0.88**	0.83	0.87	0.84	0.81
AL	25%	**0.92**	0.92	0.83	0.89	0.82
AL	50%	**0.94**	0.93	0.86	0.90	0.91
AL	75%	**0.94**	0.93	0.86	0.92	0.93
AL	90%	**0.95**	0.94	0.86	0.92	0.93
CP	25%	**0.86**	0.84	0.82	0.83	0.66
CP	50%	**0.90**	0.84	0.85	0.85	0.71
CP	75%	**0.89**	0.85	0.83	0.85	0.80
CP	90%	**0.91**	0.88	0.85	0.85	0.60

4.3 Spatial Graph Analysis

We next analyze the spatial evolution of link prediction in SLNs by exploring how combining SLNs across different classrooms affects model performance (addressing **Hypothesis 2** from Sec. 1). To evaluate this, in Tab. 2, we compare the performance of the models when trained on individual SLNs versus on combined SLNs (i.e., 'GNN iso' and 'GNN all'). The results reveal how merging SLNs positively impacts model performance across different stages of the course. For example, the AUC for VS improves from an average of 0.88 to an average of 0.94 when combined with others over the course progression. Moreover, our results show that, although combining SLNs generally improves AUC performance, particularly in smaller or sparser datasets like VS and CP, the gains are less pronounced in larger classrooms such as AL and ML, where the SLN topological structure is already rich and adding more data to it may not affect its topological significance in a meaningful way. This suggests that the benefits of spatial aggregation are not solely due to having more data, but rather depend on the compatibility of interaction patterns across classrooms. These results support **Hypothesis 2** from Sec. 1, affirming and revealing the importance and timing of spatial aggregation.

4.4 Spatiotemporal Graph Analysis

Table 3: Hypothesis testing (one-sided t-test, $\alpha = 0.10$) comparing GNN isolated (IS) vs. GNN combined (CO) vs. CNN baseline (CNN) at 25% and 75% course progress. Each row compares spatial performance, while reading down the table reveals temporal trends across progress stages.

Models	Datase	Progress	p-value	Decision
IS vs CO	AL	25%	4.18e−1	Fail to Reject H_0
IS vs CO	AL	75%	8.03e−2	Reject H_0
CNN vs CO	AL	25%	6.02e−3	Reject H_0
CNN vs CO	AL	75%	1.25e−1	Fail to Reject H_0
IS vs CO	CP	25%	2.90e−2	Reject H_0
IS vs CO	CP	75%	1.42e−2	Reject H_0
CNN vs CO	CP	25%	5.75e−8	Reject H_0
CNN vs CO	CP	75%	1.23e−8	Reject H_0
IS vs CO	VS	25%	6.86e−4	Reject H_0
IS vs CO	VS	75%	8.00e−6	Reject H_0
CNN vs CO	VS	25%	8.13e−7	Reject H_0
CNN vs CO	VS	75%	3.7e−5	Reject H_0
IS vs CO	ML	25%	3.06e−1	Fail to Reject H_0
IS vs CO	ML	75%	6.14e−2	Reject H_0
CNN vs CO	ML	25%	5.77e−2	Reject H_0
CNN vs CO	ML	75%	2.15e−1	Fail to Reject H_0

In Secs. 4.2 and 4.3, we saw that (i) SLNs become structurally richer as a course progresses (temporal evolution) and (ii) combining multiple classroom graphs (spatial evolution) generally boosts AUC by exposing the model to a broader distribution of link patterns. However, these two dimensions do not operate independently. In particular, the benefit of combining SLNs (i.e., using spatial features of the graph) appears to depend on when in the course (temporally) the graphs are merged. Thus, in this section, we address **Hypothesis 3** from Sec. 1, which investigates whether merging SLNs at different stages of course progress leads to measurable gains in model performance.

As shown in Tab. 2, we see that combining SLNs earlier in the course leads to higher performance improvements compared to merging them at later stages. This is consistent with the intuition that early in the term, when individual SLNs are sparse, combining information across classrooms helps stabilize learning and improves performance. In contrast, in the later stages of a course, each SLN develops distinct structural characteristics, potentially reflecting subject matter, classroom dynamics, or group behavior and, as a result, attain lower performance gains upon being combined with other SLNs towards the end of the course.

Further, to highlight the superiority of our methodology, we compare our GNN-based framework to the current state-of-the-art framework for link prediction in SLNs, which consists of manually engineering fixed graph features and using them as input into a convolutional neural network (CNN) for link prediction [20], along with state-of-the-art approaches for link prediction in general OSNs, which consist of a sum pooling graph convolutional network (GCN) [10] and a Graph Attention Network (GAT) [25]. As can be seen from Tab. 2, each baseline struggles to attain consistently high performance across the spatiotemporal topology of the graph. The CNN in particular struggles due to its fixed feature engineering, whereas the GNN is able to offer high link prediction performance due to its dynamic adaptation to the SLN graph topology (via its node embeddings) and its evolution over time. This is highlighted in Tab. 2, where the GNN trained on a single SLN (GNN iso) generally outperforms the CNN baseline across all datasets and time instances. Furthermore, the GNN trained on combined SLNs (GNN all) not only outperforms the CNN but also significantly surpasses the isolated GNN as well as the other baselines in many cases, particularly in earlier stages of small courses. This demonstrates the dual benefit of our framework: first, to outperform traditional feature-based methods, and second, to exploit shared link formation patterns across SLNs to enhance predictive performance.

To further support the above observations, we perform formal hypothesis testing using a one-sided t test ($\alpha = 0.10$) comparing the AUC performance of our GNN model trained in combination (CO) with other courses against both the GNN trained in isolation (IS) on a single course and the CNN baseline (CNN). Here, we focus on the CNN baseline to demonstrate the statistical significance of using our framework's learned features via node embeddings in comparison to fixed feature engineering as currently done in state of the art link prediction frameworks [20]. The null hypothesis in each test states that CO does not outperform the baseline, while the alternative asserts that CO achieves a higher AUC. Tab. 3 summarizes the results in 25% and 75% course progress for the four SLNs. We show results at these two progress points to highlight the superiority of our method in an early and a late stage of the course. Here, we see that the improvement of our framework is statistically significant, particularly for small courses (e.g., CP and VS). Larger courses (e.g., AL and ML), on the other hand, contain sufficient training data that can be captured in varying time instances. This is largely due to the bias of the larger courses as their SLNs account for a larger partition of the spatially aggregated graph structure. Yet, we still observe statistically significant gains in AUC when comparing CO against both CNN and IS. In particular, the p-values are especially low for smaller and sparser datasets such as VS and CP, even at early progress stages. This further supports **Hypothesis 3**: the spatiotemporal consideration of SLNs generally yields stronger link prediction performance compared to the current state of the art, particularly in smaller courses (CP and VS) that suffer from an abundance of links early in the course.

5. CONCLUSION

In this work, we developed a link prediction framework in SLNs through the lens of two critical dimensions: temporal evolution and spatial aggregation. Using multiple SLNs at varying progress stages, we analyzed how SLNs develop over time and how combining multiple SLNs affects model performance. Our results show that model performance improves as the SLNs progress through the course timeline: richer interaction structures at later stages offer stronger signals for link prediction. We also found that merging SLNs from multiple classrooms can enhance model performance as spatial aggregation helped overcome data sparsity in smaller courses with lower numbers of links throughout the course progression. Finally, our analysis of the spatiotemporal

aspects revealed that the benefits of merging graphs are most pronounced early in the course, and particularly in smaller courses, which require more structure early on.

ABSTRACT

Classroom instructional behavior analysis seeks to model teacher- and student-led behaviors to support instructional quality assessment, teaching feedback, and AI-assisted classroom analytics. With the rapid progress of Large Language Models (LLMs) and multimodal learning, reliable analysis increasingly depends on well-structured multimodal datasets with pedagogically grounded behavior definitions. However, existing classroom datasets are often limited to single modalities or coarse, task-agnostic behavior categories, failing to capture fine-grained teacher–student instructional dynamics and limiting model interpretability and generalizability. To address these issues, we introduce TS-Interact (Teacher–Student Interaction Dataset), a multimodal dataset for characterizing classroom teacher- and student-led instructional behaviors. TS-Interact integrates synchronized video, audio, and text from real classroom scenarios, comprising approximately 1,000 instructional segments across multiple core subjects. Built upon an S–T interaction analysis framework, instructional behaviors are systematically decomposed into teacher-led and student-led categories, each further organized into four pedagogically motivated behavior types. All segments are manually annotated, with annotation reliability validated using the Kappa coefficient. Benchmark experiments with representative multimodal behavior recognition models demonstrate that TS-Interact achieves higher annotation consistency and improved recognition accuracy than commonly used generic classroom datasets. Overall, TS-Interact provides a high-quality multimodal benchmark with theoretically grounded behavior definitions, enabling precise and interpretable LLM-based classroom behavior analysis and supporting future research in intelligent teaching evaluation.

Classroom Instructional Behavior Analysis, Multimodal Educational Dataset, Teacher–Student Interaction, Pedagogically Grounded Annotation, LLM-based Classroom Analytics

1. INTRODUCTION

Classroom teaching behavior analysis, which involves the quantitative modeling and qualitative characterization of teacher-initiated and student-initiated behaviors during instructional activities, serves as a cornerstone for advancing modern educational practices[11]. Its application value spans three core domains: in teaching evaluation, it provides objective, data-driven evidence to complement subjective observation scales; in teaching feedback, it enables targeted improvement suggestions for teachers by identi-fying interaction bottlenecks in classroom processes; in intelligent education systems, it underpins the development of adaptive teaching modules and automated classroom monitoring tools[12]. With the rapid advancement of large language models (LLMs) and multimodal learning technologies, the integration of cross-modal information (video, audio, text) has revolutionized the way class-room behaviors are analyzed—LLMs, in particular, empower the mining of implicit semantic relationships behind behavioral sig-nals, while multimodal fusion enhances the comprehensiveness of behavior recognition[10]. This technological evolution has put forward new demands for classroom analysis research: the need for high-quality multimodal datasets with pedagogically grounded behavior definitions, which can bridge the gap between technical model training and practical educational scenarios.

However, a critical review of existing classroom datasets reveals three prominent limitations that hinder the advancement of LLM-driven multimodal classroom behavior analysis. First, in terms of modality coverage, most datasets prioritize single-modal signals (e.g., learning management system logs or video-only recordings), ignoring the comple-

https://doi.org/10.5281/zenodo.21039742

mentary value of synchronized audio and text information in capturing complex interaction dynamics such as teacher-student dialogue and experimental operation sounds[7]. Second, behavior definition frameworks are often coarse-grained and task-irrelevant. Many datasets categorize classroom behaviors into overly general types (e.g., "interaction" and "non-interaction"), failing to distinguish subject-specific behavioral characteristics such as science experiment operations and art creation practices[13]. Third, there is a lack of solid pedagogical theoretical support for behavior classification systems. Existing datasets rarely integrate classic educational theories such as student-teacher (S-T) interaction analysis, resulting in behavior taxonomies that are disconnected from teaching practice and reducing the interpretability of downstream analysis models[9]. These limitations collectively restrict the performance of multimodal and LLM-based analysis models in real classroom scenarios, leading to a mismatch between technical solutions and educational application needs.

To address the aforementioned gaps, this study introduces TS-Interact, a multimodal teacher-student interaction dataset dedicated to classroom teaching behavior analysis. The core contributions of this study are threefold. First, we construct TS-Interact, a high-quality multimodal dataset comprising approximately 1,000 teaching segments across seven core middle school subjects, which integrates synchronized video, audio, and text data collected from authentic classroom environments. Second, based on the classic S-T interaction analysis framework, we design a dual-dominant teaching behavior classification system, which divides classroom behaviors into teacher-dominant and student-dominant categories, with each category further refined into four pedagogically moti-vated subtypes, ensuring both fine-grained modeling and semantic interpretability. Third, we conduct comprehensive experiments to verify the dataset's effectiveness: we quantify annotation consistency using Kappa coefficients to ensure data quality, and per-form benchmark tests with representative multimodal behavior recognition models to demonstrate that TS-Interact outperforms general-purpose datasets in behavior recognition accuracy.

2. RELATED WORK

Classroom Instructional Behavior Analysis. Classroom instructional behavior analysis is a central topic in educational technology, aiming to model and interpret the dynamic interactions between teachers and students to support instructional evaluation and intelligent educational systems. Existing studies largely rely on single-modal data sources—video, audio, or text—enabled by advances in computer vision, speech processing, and natural language processing. Video-based approaches leverage visual cues such as posture, gestures, and movement patterns to recognize classroom behaviors[6]. While automatic recognition models (e.g., CNNs and pose-based methods) have reduced manual annotation costs, most studies adopt coarse-grained behavior categories and often fail to distinguish teacher and student roles, limiting interpretability of interaction dynamics. Audio-based methods focus on speech features and dialogue structures to analyze verbal interaction and emotional states[4]. However, these approaches are highly sensitive to noise and typically rely on shallow behavior definitions (e.g., speaking vs. silence), overlooking pedagogically meaningful interaction types. Text-based studies exploit transcribed classroom discourse and learning logs to analyze teaching content and participation quality [3]. Although semantic modeling offers interpretability advantages, such approaches are constrained by limited data scale and the lack of integration with visual and auditory cues. Overall, prior work exhibits three common limitations: coarse behavioral granularity, ambiguous subject distinction between teachers and students, and insufficient multimodal integration. These issues restrict the applicability of existing models for fine-grained, theory-aligned instructional behavior analysis.

Classroom Instructional Behavior Datasets. Several datasets have been proposed to support classroom behavior analysis; however, notable limitations remain in modality coverage, annotation granularity, and theoretical grounding. Existing datasets either focus on engagement estimation or general instructional actions, with limited representation of authentic classroom interaction dynamics[5]. Most available datasets employ single or weakly integrated modalities[8], preventing effective modeling of cross-modal behavioral cues. In addition, behavior labels are typically broad (e.g., "engaged" or "active"), lacking alignment with pedagogical constructs and obscuring distinctions between different instructional intents. More critically, many datasets are not grounded in established educational theories, resulting in annotations that reflect surface-level observations rather than interpretable instructional behaviors[1]. These limitations highlight the need for a multimodal classroom dataset that integrates synchronized video, audio, and text, adopts fine-grained and role-aware behavior definitions, and is explicitly informed by instructional theory. Addressing these gaps forms the motivation for the TS-Interact dataset proposed in this work.

3. METHODOLOGY

To provide a clear and systematic understanding of how TS-Interact is designed, constructed, and validated, this section presents the methodological framework of the proposed dataset from theory to practice. As illustrated in Fig.1, our method follows a structured pipeline that starts from a pedagogically grounded instructional behavior modeling framework, proceeds through multimodal data collection, preprocessing, and rigorous annotation, and culminates in dataset validation via representative multimodal baseline models. This end-to-end design ensures that the dataset is not only empirically reliable but also theoretically interpretable, enabling fine-grained characterization of teacher–student instructional behaviors. In the following subsections, we first introduce the theoretical foundation underlying the instructional behavior taxonomy, then describe the dataset construction and annotation process in detail, and finally report validation experiments that demonstrate the effectiveness and adaptability of TS-Interact for multimodal classroom behavior analysis

3.1 Theoretical Foundation of Instructional Behavior Modeling

TS-Interact is built based on the Teacher-Student (S-T) interaction framework, which originates from the classic classroom interaction theory [2] and has been modernized in recent multimodal educational research. The framework

Table 1: Classroom Teaching Behavior Categories

Major Category	Subcategory	Category
Teacher-led Teaching Behavior	Knowledge Presentation	Explain and state; Summarize the lecture; Evaluation summary; Demonstrate and explain
	Guiding Questions	Raise a question; Assign tasks; Follow up with a counter-question
	Resource Display	Physical display; Experimental demonstration; Text display; Picture display; Data display; Blackboard writing display
	Process Management	Activity guidance; Communication guidance; Order management; Emotional motivation; Performance evaluation
Student-led Teaching Behavior	Independent Exploration	Independent thinking; Information query
	Oral Expression	Student read aloud; Speak and answer together; Student's direct answers
	Operational Practice	Start writing by hand; Hands-on operation
	Cooperation and Exchange	Group discussion; Report conversation; Work display

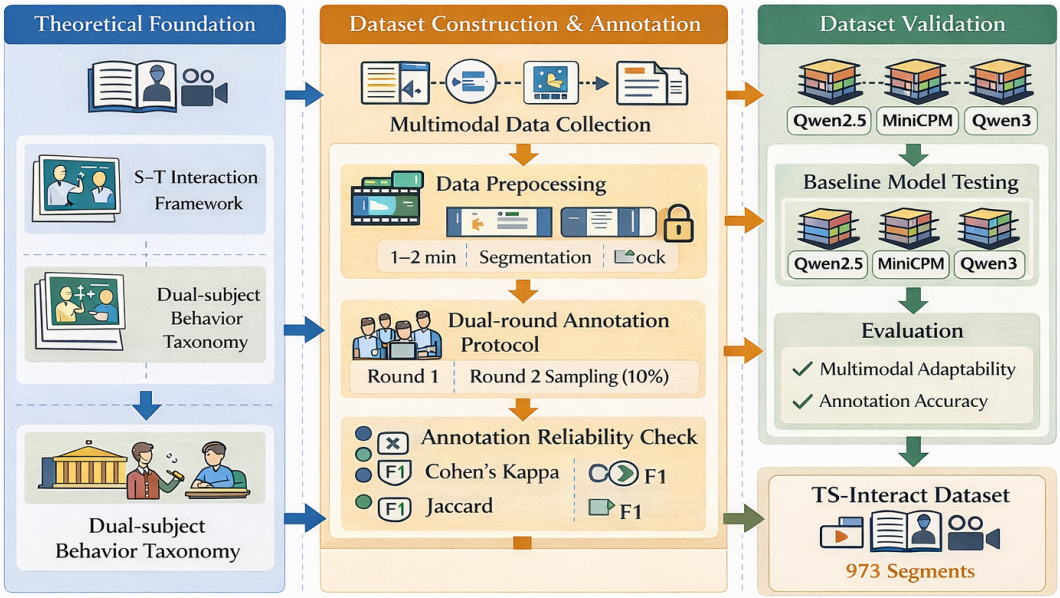

Figure 1: The workflow for constructing the dataset of T-S interaction

clearly defines teacher-led and student-led teaching behaviors, providing a rigorous theoretical foundation for multimodal observation and teaching semantic alignment. Both the behavior classification system and the three-layer annotation scheme in this paper are strictly designed based on this theory. The instructional behavior annotation system constitutes the theoretical foundation of the TS-Interact dataset, enabling structured and interpretable modeling of classroom teaching and learning processes. Existing classroom behavior annotation schemes often adopt generalized, subject-agnostic categories, which fail to capture the core logic of teacher–student interaction and limit their applicability to multimodal analysis. To address this issue, TS-Interact grounds its annotation design in an interaction-oriented pedagogical framework, ensuring both theoretical validity and annotation feasibility.

Student–Teacher Interaction Framework. TS-Interact adopts the Student–Teacher (S–T) interaction analysis framework as its theoretical basis, viewing classroom instruction as a dynamic process formed through continuous interaction between teachers and students. In this framework, teachers primarily guide and regulate instructional processes, while students actively participate in learning activities. Since instructional effectiveness emerges from this bidirectional interaction, instructional behaviors must be explicitly associated with their initiating subjects and pedagogical functions. This subject-aware design provides a clear theoretical foundation for aligning multimodal observations with instructional semantics.

Dual-subject Instructional Behavior Taxonomy. Based on the S–T interaction framework, TS-Interact employs a dual-subject instructional behavior taxonomy that distinguishes teacher-led and student-led behaviors, as shown in Table 1. Teacher-led behaviors describe instructional actions such as

content presentation, task guidance, resource support, and process management, while student-led behaviors capture learning activities including exploration, expression, operation, and collaboration. This hierarchical taxonomy ensures clear behavioral boundaries, reduces annotation ambiguity, and aligns each behavior category with observable multimodal signals from video, audio, and text. As a result, the proposed taxonomy supports reliable annotation, interpretable modeling, and effective multimodal behavior recognition.

3.2 Dataset Construction and Annotation

Multimodal Classroom Data Collection. To ensure the authenticity, representativeness, and disciplinary diversity of the dataset, all classroom videos used in this study were collected from the National Smart Education Platform for Primary and Secondary Schools and several provincial-level smart education platforms. All recorded lessons available on these platforms had been officially reviewed and approved by educational administrative authorities, ensuring high instructional quality and authoritative reliability. The collected videos represent real-world daily teaching scenarios rather than artificially designed experimental classrooms, with clear and stable audio–visual signals. A total of 41 complete classroom recordings were initially selected, covering seven academic subjects: physics, art, mathematics, chemistry, Chinese, history, and biology. This subject diversity enables the dataset to reflect varied instructional styles and interaction patterns across science, humanities, and arts disciplines, supporting broad applicability in multimodal classroom behavior analysis.

Data Preprocessing and Segmentation. To accurately capture meaningful instructional behavior units and meet the requirements of fine-grained behavior recognition, all collected classroom videos were segmented by trained personnel with an educational technology background. Using professional video editing tools, each full-length recording was divided into short clips with an average duration of 1–2 minutes. During segmentation, special care was taken to avoid splitting a coherent teacher–student interaction across multiple segments, ensuring that each clip contains a complete behavioral unit or a continuous interaction sequence. Segments with blurred visuals, severe background noise, missing instructional content, or disrupted audio–visual signals were excluded. For science experiment lessons, clips with unclear experimental procedures or missing key operational steps were further removed. All original videos had already undergone privacy protection procedures on the hosting platforms, and additional audio de-sensitization was applied to strictly comply with educational data ethics and privacy regulations. Classroom automated monitoring is now widely used in school education and has been generally accepted by teachers and students. Therefore, the potential negative impact of automated monitoring on teacher-student teaching interaction is negligible.

Dual-round Annotation Protocol. To enhance annotation reliability, a dual-round independent annotation protocol was adopted. The annotation team consisted of four annotators holding master's degrees in educational technology, all of whom had solid theoretical training and experience in multimodal data analysis. Prior to formal annotation, the annotators participated in a one-day centralized training session, which included theoretical instruction on the annotation taxonomy, detailed explanation of category definitions and decision rules, and hands-on practice with annotated and unannotated samples. In the first round, all annotators independently labeled the full dataset in isolated environments, with no communication permitted. One month later, to mitigate memory bias, a second-round annotation was conducted on a randomly sampled subset of 10% of the data (100 segments). The sampled segments preserved the original subject distribution and were randomly assigned to annotators such that no annotator re-labeled their own previous samples. All annotations in the second round were completed strictly according to the same guidelines, ensuring independence between rounds.

Annotation Reliability and Quality Control. To verify the consistency and reliability of the multi-label annotations, a two-dimensional evaluation framework was employed, addressing both label agreement and label set similarity. At the label level, Cohen's Kappa coefficient was used to assess whether individual behavior labels were consistently assigned. Following standard practice, values above 0.8 indicate almost perfect agreement, while values between 0.6 and 0.8 indicate high agreement. At the set level, the Jaccard coefficient and set-level F1 score were adopted to evaluate the overlap and balance of the complete label sets assigned to each segment, accommodating variations in the number of labels per sample. All annotation results were organized into a structured dataset, converted into binary label representations, and evaluated using Python-based scripts. The results demonstrate high consistency across all metrics, confirming the reliability of the annotation process.

Dataset Statistics and Content. As shown in Table 2, TS-Interact consists of 973 multimodal classroom segments, each with an average duration of 1–2 minutes, enabling fine-grained quantitative analysis of instructional behaviors at the interaction unit level. The dataset covers seven academic subjects, with physics (25.4%) and art (21.3%) forming the largest portions, followed by mathematics and chemistry (both 14.3%), ensuring balanced cross-disciplinary representation across science, humanities, and art domains. From a behavioral perspective, teacher-led behaviors dominate the dataset, with guiding question behaviors occurring most frequently (1,155 instances), followed by process management (539), knowledge presentation (538), and resource display (428). Student-led behaviors exhibit a complementary but less frequent distribution, where oral expression (690) constitutes the primary form of learner participation, while independent exploration (158), practical operation (187), and collaborative communication (16) reflect varying levels of learner autonomy and interaction intensity. Annotation quality is quantitatively supported by high inter-annotator agreement. Label-level consistency achieves an average Cohen's κ of 0.779 and a micro-average κ of 0.808, while set-level evaluation yields a Jaccard coefficient of 0.787 and an average set-level F1 score of 0.834. These quantitative indicators demonstrate that TS-Interact provides statistically reliable, behaviorally diverse, and well-balanced data support for multimodal instructional behavior analysis.

Fig.2 provides representative visual samples from TS-Interact,

Table 2: Core Dataset Statistics of TS-Interact

Dimension	Attribute	Description / Statistics
Data Scale	Total teaching segments	973 multimodal classroom segments
	Average segment duration	1–2 minutes per segment
	Data source	National and provincial smart education platforms
	Classroom setting	Authentic middle school classrooms (non-experimental)
	Privacy protection	Platform anonymization and audio de-sensitization
Subject Coverage	Subject distribution	Physics (247), Art (207), Mathematics (139), Chemistry (139), Chinese (91), History (87), Biology (63)
Behavior Distribution	Teacher-led behaviors	Knowledge presentation (538), guiding questions (1155), resource display (428), process management (539)
	Student-led behaviors	Independent exploration (158), oral expression (690), practical operation (187), collaborative communication (16)
Annotation Quality	Annotators	4 trained annotators with educational technology background
	Annotation protocol	Dual-round independent annotation with a one-month interval
	Label-level consistency	Average Cohen's Kappa Coefficient:0.779, Micro-average Cohen's Kappa Coefficient:0.808
	Set-level consistency	Average Jaccard Coefficient:0.787, Average Set-level F1 Score:0.834, Average Difference in Number of Labels:0.660

directly demonstrating the authenticity and high quality of the dataset. All samples are extracted from real, non-experimental middle school classrooms, preserving natural instructional rhythms, teacher–student interactions, and classroom layouts without staged or scripted behaviors. The visual examples show clear correspondence between annotated behavior labels and observable multimodal cues, such as teacher gestures, student postures, gaze directions, and interactions with instructional resources. This alignment indicates that the annotations are grounded in concrete visual and contextual evidence rather than abstract or inferred descriptions. Moreover, the diversity of scenes, subjects, and interaction patterns visible in the samples reflects the broad subject coverage and behavioral variability reported in Table 2. Together, these image-based samples substantiate the quantitative statistics by providing intuitive evidence of data realism, annotation reliability, and semantic clarity, reinforcing TS-Interact as a high-quality benchmark for multimodal instructional behavior analysis. To facilitate transparency and reproducibility, samples from the TS-Interact dataset has been made publicly available. Interested researchers can access these examples via the following link: https://osf.io/5q7kj/overview?view_only=6847956cd787410aa72f9cd407a0da91

3.3 Dataset Validation

Baseline Models for Multimodal Behavior Recognition. To evaluate the adaptability and effectiveness of the TS-Interact dataset for fine-grained classroom instructional behavior recognition, three representative multimodal baseline models were selected. All chosen models are lightweight, open-source, and easy to reproduce, with strong multimodal fusion capabilities, making them suitable as general benchmarks for assessing dataset quality rather than pursuing model-level state-of-the-art performance. The Qwen-2.5-Omni-3B (Qwen-2.5) model was selected due to its efficient multimodal fusion design and moderate parameter scale, which allows effective processing of video, audio, and textual inputs. It adopts a three-stage architecture consisting of single-modality feature extraction, cross-modal fusion via attention mechanisms, and behavior classification through fully connected layers, making it well aligned with the multimodal characteristics of TS-Interact. MiniCPM-V-4.5 (MiniCPM-V) emphasizes enhanced visual–language alignment and logical reasoning capabilities, enabling it to capture fine-grained instructional interaction patterns such as teacher–student question–answer dynamics. Its strong generalization ability makes it suitable for evaluating the discriminability and pedagogical rationality of the proposed annotation system. Qwen3-VL-4B-Thinking (Qwen3) adopts a dual-branch fusion architecture, where the visual branch extracts spatiotemporal video features and the textual branch models semantic information from transcribed classroom discourse, with audio features mapped into the textual space. Adaptive fusion between the two branches enables robust behavior recognition under limited data conditions, making this model particularly appropriate for validating dataset representativeness. Together, these three models cover diverse multimodal fusion strategies and provide a comprehensive evaluation of the dataset's adaptability, annotation quality, and practical usability.

Experimental Setup. The TS-Interact dataset was split into training and test sets using subject-stratified sampling with an 80%/20% ratio to maintain disciplinary balance. All splits were performed at the segment level to prevent data leakage. Classification performance was evaluated using Accuracy, Precision, Recall, and Macro-F1 to reflect both overall recognition and robustness to imbalanced behavior categories. Generation quality was assessed with ROUGE-1/2/L and BLEU-4, measuring semantic overlap and content completeness between generated descriptions and gold annotations. All baseline models were evaluated under identical settings within the LlamaFactory framework (max input length 2048, batch size 4, max generation length 384, temperature 0.01, nucleus sampling 1.0), with a fixed random seed (42) to ensure reproducibility.

Evaluation Results and Analysis. Table 3 reports the quanti-

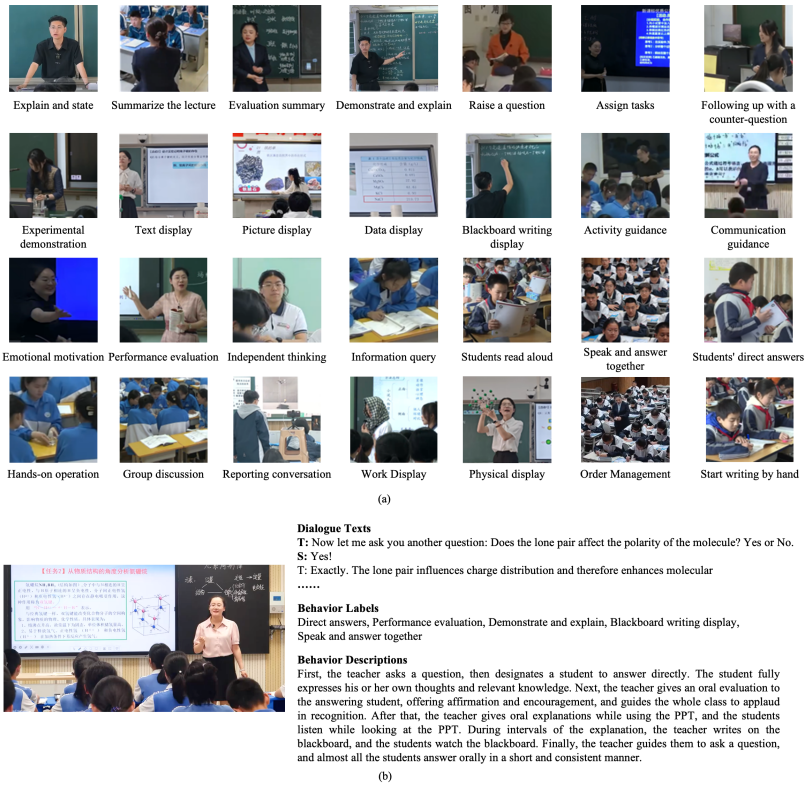

Figure 2: (a) Examples of Teacher-and-Student-led instructional behaviors in TS-interact (single-frame screenshot from a multimodal segment) (b) Annotated segment example in TS-Interact.

Table 3: Average Performance of Baseline Models on TS-Interact Across Seven Subjects

Model	F1	Accuracy	Precision	Recall	ROUGE-1	ROUGE-2	ROUGE-L	BLEU-4
Qwen3	**0.6582**	**0.1482**	**0.6525**	**0.6625**	**0.3572**	**0.1641**	**0.3330**	**0.0913**
Qwen-2.5	0.6275	0.1005	0.6208	0.6345	0.3315	0.1455	0.3068	0.0781
MiniCPM-V	0.5788	0.0615	0.5704	0.5860	0.2974	0.1239	0.2753	0.0647

tative results averaged over seven subjects. Qwen3 achieves the strongest overall performance, obtaining a Macro-F1 of 0.6582 and consistently outperforming other baselines across all generation metrics (e.g., ROUGE-L 0.3330, BLEU-4 0.0913). Compared with MiniCPM-V, Qwen3 yields a relative improvement of 13.7% in Macro-F1 and 21.8% in ROUGE-1, indicating superior alignment between multimodal inputs and fine-grained instructional behavior labels. Qwen-2.5 shows competitive results with reduced model size, suggesting a favorable trade-off between efficiency and accuracy. The consistent ranking of models across both classification and generation metrics demonstrates strong metric agreement and confirms the internal consistency of the evaluation protocol. Overall, the clear performance gaps among baselines highlight the discriminative power of TS-Interact and validate its suitability as a high-quality benchmark for multimodal classroom behavior recognition and instructional modeling.

4. DISCUSSION

This study presents TS-Interact as a multimodal classroom interaction dataset grounded in a structured and pedagogically informed teaching behavior taxonomy. From the perspective of the overall research design, several important insights emerge.

First, the results demonstrate that incorporating multimodal information is essential for fine-grained instructional behavior understanding. Across all baseline models, performance gains are consistently observed when visual, auditory, and textual cues are jointly leveraged, indicating that classroom teaching behaviors cannot be reliably inferred from a single modality alone. This finding aligns with educational theories that emphasize the embodied and situational nature of teaching, where gestures, visual materials, and classroom dynamics play a critical role alongside spoken language.

Second, the proposed teaching behavior annotation system contributes to more scientifically grounded behavior modeling. By explicitly distinguishing teacher-led and student-led behaviors and further decomposing them into pedagogically meaningful subcategories, TS-Interact avoids overly coarse

or purely action-level labels. This hierarchical structure enables models to capture both instructional intent and interaction patterns, which is reflected in improved classification stability and more coherent generation outputs. Compared with prior classroom datasets that rely on flat or loosely defined labels, the TS-Interact taxonomy provides clearer semantic boundaries and stronger interpretability.

Third, the performance gap among different multimodal large language models highlights both the promise and current limitations of general-purpose MLLMs in educational scenarios. While advanced models achieve reasonable results on behavior recognition and description, their accuracy remains relatively low, suggesting that classroom interaction understanding poses challenges beyond conventional vision-language tasks. This indicates opportunities for future work on education-specific adaptation, multimodal alignment, and reasoning mechanisms tailored to instructional contexts.

Finally, this study also has limitations. The dataset focuses on structured classroom settings and predefined academic subjects, which may limit direct generalization to informal or online learning environments. In addition, although the annotation framework is designed to be extensible, further validation across diverse educational cultures and instructional styles is still needed. Addressing these limitations will be an important direction for future research.

5. CONCLUSION

In this paper, we introduced TS-Interact, a multimodal classroom interaction dataset designed to support fine-grained analysis of teaching and learning behaviors. By integrating video, audio, and textual information with a pedagogically grounded annotation system, TS-Interact provides a more comprehensive and interpretable representation of classroom instructional dynamics. We conducted extensive experiments using state-of-the-art multimodal large language models, evaluating both classification and generation tasks. The results demonstrate that multimodal information is critical for understanding instructional behaviors and that the proposed teaching behavior taxonomy enables more structured and meaningful modeling of classroom interactions. Overall, TS-Interact offers a valuable benchmark for advancing multimodal educational AI research, particularly in areas such as classroom behavior understanding, instructional analysis, and intelligent tutoring systems. We hope this dataset will facilitate future studies on interpretable, scalable, and pedagogically informed multimodal learning models, and contribute to the development of AI systems that better support teaching and learning in real-world classrooms.

In future work, we plan to expand TS-Interact to cover a broader range of disciplines, extending from seven to nine subjects while maintaining a balanced distribution across categories. In addition, to complement the current validation based on lightweight multimodal models, we will incorporate larger-scale multimodal models to further examine the dataset's scalability and robustness. Beyond dataset expansion and validation, we aim to explore interdisciplinary instructional behavior analysis, dataset-driven model optimization, and the development of ethically grounded AI applications for educational contexts.

ABSTRACT

Artificial students—models that simulate how learners act and respond within educational systems—are a promising tool for evaluating tutoring strategies and feedback mechanisms at scale. However, most existing approaches rely on prompting large, proprietary language models, limiting adaptability to specific courses and raising concerns around privacy, cost, and dependence. In this work, we propose a framework for training open-weight artificial programming learners directly from authentic student process data. Our approach serializes temporal log traces into a conversational format, representing each student's problem-solving process as a dialogue between the learner and their automated assessment system. Student code submissions and environment feedback, such as test outcomes, grades, and error traces, form alternating conversational turns, enabling models to learn from the iterative debugging process. We additionally introduce a training pipeline combining supervised fine-tuning with preference optimization to align models with authentic student debugging behavior. We evaluate our framework by training Qwen models at 4B and 8B scales on a large-scale dataset of real student submissions to Python programming assignments. Our results show that incorporating environment feedback strengthens models' ability to replicate student debugging behavior, improving over both prior code-only approaches and prompted large language models baselines in functional alignment and code similarity. We release our code to support reproducibility.

1. INTRODUCTION

To better support learners at scale, computing education research has long relied on models of students built from the rich log data collected as they solve programming assignments [17, 46]. Much of this work focuses on capturing what students know, such as estimating mastery over concepts through knowledge tracing [7, 18, 44], or identifying misconceptions that explain incorrect outcomes [40]. These models provide valuable insights into learning progress and have informed the design of successful interventions [3]. However, while such approaches are effective for analyzing student cognition and predicting outcomes, operationalizing interventions based on these models remains challenging. In many settings, what is needed is not only an estimate of what a student knows, but a model of how a student behaves: how they act, react, and progress when interacting with learning systems. This has motivated growing interest in *artificial students*—models that act as stand-ins for real learners by generating plausible sequences of actions [43, 26, 5]. When realistic, artificial students could enable the simulation of student–system interactions and support controlled experimentation, such as comparing tutoring strategies, evaluating feedback policies, or assessing the difficulty of programming tasks, as already done in prior works [32, 12, 29], without requiring repeated classroom deployments. Despite this promise, existing artificial student models remain limited, particularly in programming education. Recent work using large language models has shown that it is possible to generate student-like code [23, 25], but these approaches often rely on prompting alone and tend to reproduce surface-level error patterns rather than the dynamic nature of real student debugging. In particular, existing methods remain limited in their ability to realistically simulate how learners tackle programming assignments.

In this work, we leverage the rich process data already collected by programming learning environments to train small and medium size open-weight models for *within-assignment student simulation* [27, 35]. Since student data is sensitive and institutional, this offers a more practical path than prompting proprietary systems [35], keeping data local while learning the iterative debugging patterns that prompting alone cannot reliably elicit. Our core innovation is to represent each problem-solving trajectory as a dialogue between a student and their learning environment. Student code submissions are encoded as assistant turns, while outputs from automated assessment systems (e.g., unit-test outcomes, or grader messages) form the corresponding user turns. By adopting the conversational format commonly used to interact with language models, we turn raw log traces into structured sequences that capture how a student's code evolves in response to feedback. This representation enables chat-capable language models to learn from iterative debugging sequences without requiring architectural modifications.

To train artificial students from this conversational representation, we propose a pipeline combining supervised fine-tuning with offline preference optimization via Direct Preference Optimization [33]. We additionally explore online preference optimization methods based on Group Relative Preference Optimization [50]. We evaluate our framework on FalconCode [9], a large-scale dataset of student submissions to Python programming assignment, training Qwen models [41] at 4B and 8B scales. Our results show that incorporating environment feedback strengthens models' ability to replicate student debugging behavior, improving over both prior code-only baselines and prompted large language models in functional alignment and code similarity.

Summary contributions. Our main contributions are:

- **Student-environment serialization.** We introduce a conversational formulation of student–environment interactions that enables language models to learn students iterative debugging processes.
- **A training methodology for artificial students.** We propose a pipeline combining supervised fine-tuning and preference optimization to align language models with authentic student coding trajectories.
- **Empirical evaluation on real student data.** We validate our framework on a large-scale dataset of student programming submissions, showing that environment feedback and preference optimization yield complementary gains in simulation realism. We also release our code: `KoutchemeCharles/edm-conv-ser`

2. RELATED WORK

A complementary line of work focuses on *knowledge tracing* (KT), whose primary goal is to estimate a student's mastery of knowledge components across exercises. While early approaches focused exclusively on predicting success on future assignments, more recent methods leverage language-model–based architectures to predict students' first submission to following assignments and the associated outcomes [24, 13, 15]. While such methods may predict student programs, this prediction serves mainly as an intermediate signal for updating knowledge estimates across programming tasks, not as a goal in itself. In contrast, we aim to obtain models that can be unrolled over multiple steps within a single assignment to generate and simulate problem-solving trajectories. Closer to our work in the educational domain is Miroyan et al. [27], who train open-weight language models using supervised fine-tuning to predict a student's next submission to Python programming assignments given a limited context of prior attempts. Their work shows that trained language models perform better than prompted LLMs. Ross et al. [35] go further by fine-tuning pre-trained language models on 3.8 million traces from a block-based educational programming platform, showing that models trained on real edit sequences yield richer representations of student behavior than those trained on final programs alone. However, neither approach incorporates the learning environment's responses to student submissions. Yet, serializing structured data into conversational format for language model training is well-established in NLP, with extensive work on synthetic dialogue generation [28, 11, 49] and math-informed dialogues [1].

Closest to our approach is OpenCodeInterpreter [51], which fine-tunes open-weight language models on multi-turn code-execution dialogues to improve code generation and refinement abilities. While their approach also serializes execution feedback into multi-turn dialogs, our work differs in two key aspects. First, our goal is to reproduce student problem-solving behavior, not to improve code generation; we train on authentic student trajectories rather than synthetic expert-generated interactions refined through execution outputs. Second, we develop preference optimization methods specifically adapted to student programming trajectories, leveraging infrastructure tied to learning environments, in particular the autograder, to construct preference pairs for training.

3. FROM LOGS TO DIALOGS

In this section, we introduce our approach for transforming student log data into suitable data for student simulation. Our work assumes that students interact with an automated assessment system returning summative feedback [6].

3.1 Assumptions

We assume access to a deterministic grading function which, for a submitted program a to a programming assignment d, can return two observable components: $v_r^{(d)}(a) = r$ and $v_f^{(d)}(a) = o$. The numerical score $r \in [0, 1]$ measures the correctness of the executed program (e.g., proportion of passed test cases). The textual feedback o contains the textual outcome of executing that submission: summaries of passed tests, numerical grades, and/or even runtime error traces, depending on what each dataset provides. We do not assume any internal structure of the (summative) feedback, only that it is consistently produced and directly observable in the logs. We also assume access to a dataset of institutional log data containing sequences of graded submissions and their outcomes: $\mathcal{D} = \{(d^i, s^i)\}_{i=1}^N$, where d^i denotes an assignment textual description and $s^i = (u_1^i, u_2^i, \ldots, u_{T_i}^i)$ denotes the sequence of graded interactions for a single student on that assignment. Each entry $u_t^i = (a_t^i, o_t^i)$ contains the submitted program a_t^i and its outcome $o_t^i = v_f^{(d^i)}(a_t^i)$. The trajectory length T_i equals the number of graded submissions recorded for assignment d^i.

3.2 Serialization

We represent student programming logs using the standard conversational format used to train and interact with chat-capable language models [31]. We structure each trajectory as a dialogue where the `user` role represents the automated assessment system and the `assistant` role represents a student learning how to program. The `system` prompt establishes the context: the model is a novice student learning to program, solving assignments while interacting with a learning environment that provides summative feedback. The initial `user` message provides the assignment description d_i and any relevant context. Each logged interaction $u_t^i = (a_t^i, o_t^i)$ then maps to two conversational turns: the student's code submission a_t^i appears as an `assistant` turn, followed by the grading environment's feedback o_t^i as the next `user` turn. This alternating structure naturally captures the iterative debugging process: students write code, receive feedback, then revise based on that feedback. Below is an illustration using a simple Python assignment:

System

```
You are a first-year novice student learning
programming in Python. Solve the given programming
assignment(s). You will be interacting with a learning
environment which will provide you with summative feedback.
```

User

```
Write a Python function called "compute_average".
The function should take as argument a (non-empty) list of
integers and returns the mean over those elements.
```

Assistant

```
def compute_average(nums):
    total = nums[0]
    for i in nums:
        total += i
    return average / len(nums)
```

User

```
Runtime error: undefined variable "average".
```

Assistant

```
def compute_average(nums):
    total = nums[0]
    for i in nums:
        total += i
    return total / len(nums)
```

User

```
Tests passed: 1/8
```

Assistant

```
def compute_average(nums):
    total = 0
    for i in nums:
        total += i
    return total / len(nums)
```

User

```
Tests passed: 8/8
```

4. TRAINING ARTIFICIAL LEARNERS

In this section, we present our training pipeline for training a language model π_θ to simulate how programming students solve assignments. Our core pipeline combines supervised fine-tuning with offline preference optimization on a serialized dataset $\mathcal{D}$. We additionally explore online preference optimization as an alternative to the offline stage.

4.1 Supervised Fine-tuning

The first method is to simply supervised finetune our model π_θ using the negative log likelihood (i.e., SFT) objective:

$$\mathcal{L}_{\text{SFT}}(\theta, \mathcal{D}) = -\sum_{s^i \in \mathcal{D}} \sum_{t=1}^{T_i} \log \pi_\theta\left(a_t^i \mid u_{<t}^i\right).$$

Following prior work, we only backpropagate the loss on assistant turns [10] containing student code submissions. The supervised fine-tuning step enables models to quickly learn patterns of student problem-solving.

4.2 Offline Preference Optimization

We use Direct Preference Optimization [33] (DPO), an offline preference optimization algorithm that aligns language models using pairwise preference datasets. This algorithm has shown much success in applied AI in education [21, 48, 38]. In this work, we construct preference datasets by forming contrastive pairs of candidate continuations from the same student trajectory. Let $u_{\leq t}^i$ denote a sampled partial trajectory of a student up to step t. The preferred continuation is the student's immediate next submission a_{t+1}^i, while the dispreferred continuation is the first following submission with a different grade. Formally, if we define:

$$k^\star(i,t) = \min\left\{k \in [2, T_i - t] : v_r^{(d)}(a_{t+k}^i) \neq v_r^{(d)}(a_{t+1}^i)\right\}.$$

then the resulting preference dataset is :

$$\mathcal{D}_{\text{DPO}} = \left\{\left(u_{\leq t}^i, a_{t+1}^i, a_{t+k^\star(i,t)}^i\right)\right\}_{i=1,\ldots,N;\ t \in \mathcal{T}_i}.$$

We believe $a_{t+k^\star(i,t)}^i$, the nearest semantically distinct code the student actually wrote, provides a high-quality contrast that teaches the model *why* students submit specific solutions at each step, preventing models from jumping prematurely to fully correct solutions, a pattern observed in prior work [27]. Using the resulting dataset, we optimize our model using the DPO loss [33]:

$$\mathcal{L}_{\text{DPO}}(\theta) = -\mathbb{E}_{(u_{\leq t}^i, a_{t+1}^i, a_{t+k}^i) \sim \mathcal{D}_{\text{DPO}}} \left[\log \sigma\big(r_\theta(u_{\leq t}^i, a_{t+1}^i) - r_\theta(u_{\leq t}^i, a_{t+k^\star(i,t)}^i)\big)\right] \quad (1)$$

where σ is the sigmoid function and

$$r_\theta(u, a) \triangleq \beta \log \frac{\pi_\theta(a \mid u)}{\pi_{\text{ref}}(a \mid u)}. \quad (2)$$

with π_θ being the model being optimized and π_{ref} being the reference policy (the model before the start of the optimization (often π_{SFT})). In essence, Equation (1) penalizes the model based on how much more it prefers the dispreferred generation over the preferred one using an implicit reward (Equation (2)), defined by the model probabilities, with β controlling how much the trained model weights θ can deviate from their initialization point (e.g., the SFT weights).

4.3 Online Preference Optimization

We additionally explore whether online preference optimization can exceed offline methods for student simulation. Specifically, we use a variant of Group Relative Preference Optimization (GRPO) [16], an online algorithm that iteratively (1) samples multiple candidate next-step programs from the current policy, (2) evaluates them through a reward function, and (3) updates the model according to their relative quality. At each iteration, given a trajectory prefix $u_{\leq t}^i$, we sample $G = 4$ candidate next-step programs using top_p sampling. Each candidate is scored using a discrete reward that captures two complementary aspects [19] of next-step program prediction: functional alignment and syntactic similarity. Candidates whose abstract syntax tree exactly matches the student's actual next submission receive the highest reward (+2.0). Candidates that do not match exactly but achieve the same grade as the student's next attempt receive a smaller reward (+1.0). Candidates that fail to compile are penalized (-1.0), while all remaining candidates receive no reward. This tiered design prioritizes reproducing the student's specific solution while still rewarding functionally equivalent behavior, and aligns with outcome-based reward practices in code generation [22]. We update model parameters using DAPO [50], a more stable version of the original GRPO algorithm. Due to space constraints, we refer the reader to the original paper and our code base for the full loss formulation.

5. EXPERIMENTS

In this section, we detail the components of our experiments aimed at evaluating the utility of our framework.

5.1 Dataset

We evaluate our framework using FalconCode [9], a large-scale CS1 Python programming dataset from the United States Air Force Academy. The dataset includes student submissions, the associated grades, and the course autograder, which we used to regenerate the same detailed summative feedback students received during the course, showing pass/fail and expected outputs per test case. FalconCode contains three assignment difficulty levels: "skill", "lab", and "project". We excluded project assignments (lacking automated tests) and skill assignments (1–10 lines of code). Lab assignments represent medium-sized programs (10–50 lines). To manage the costs of running our experiments, we arbitrarily selected the assignment with the highest number of submissions from each lesson regrouping assignments targetting similar concepts. We retained trajectories where students passed at least one test, as all-failing trajectories often reflect non-serious attempts. We further removed non-compiling submissions but retained runtime errors and traces as environment feedback. We leave the handling of syntax errors to future work. FalconCode spans three semesters. To mimic realistic deployment, we use data from Spring 2021 for training, and evaluate on a randomly sampled susbet of 1000 trajectories from Spring 2022.

5.2 Models

We fine-tune two open-weight language models from the Qwen family [41]: `Qwen3-4B-Instruct` and `Qwen3-8B`. We selected these models for their strong performance on coding benchmarks and to study model size effects on student simulation quality.

Model variants. We evaluate variants to isolate the contribution of our framework components. As a baseline to prior work [27], we train models *without* environment feedback (**PARA**). Within our framework, we compare **SFT** (supervised fine-tuning), **DPO** (offline preference optimization), and **DAPO** (online preference optimization). For both preference optimization, we start training from the SFT weights.

Training setup. We use `unsloth` [8] to enable long-context fine-tuning on NVIDIA V100 GPUs with 32 GB of VRAM, using `triton`, our institution research cluster. All models are fine-tuned with QLoRA [10], following established hyperparameter recommendations [39, 42]: rank $r = 8$, $\alpha = 16$. Models are trained with a maximum context length of 4096 tokens. When trajectories exceed this limit, we remove earlier assistant turns until the sequence fits, creating a dynamic sliding window over recent submissions. For PARA models, unlike [27] who use a fixed window of $k = 4$ prior submissions, we dynamically limit prior submissions based on the context window size such that all trained models operate under the same computational constraints. We use a cosine learning rate of 1×10^{-4} for SFT variants (including PARA) (one epoch) and 1×10^{-5} for preference optimization, with $\beta = 0.5$ for DPO following [38]. For SFT variants and DPO, we select the best checkpoint based on validation loss from 20% of training data. For DPO, we sample all positions from all available trajectory prefixes from the training set. For GRPO, we sample two positions from each trajectory due to computational costs, generating $G = 4$ possible attempts per trajectory.

In-context learning baselines. To assess the value of fine-tuning, we include in-context learning (ICL) baselines using **BASE** model variants without training. We also evaluate the proprietary `GPT-5-mini` [30] model under the *minimal* reasoning configuration (see OpenAI model documentation).

5.3 Evaluation

For each test trajectory, we evaluate model predictions at all possible starting positions $t > 2$. Given a partial history $u^i_{\leq t}$, we autoregressively roll out the model for up to 5 steps using greedy-decoding. At each rollout step $j \in \{1, \ldots, 5\}$, the model generates a submission $\hat{a}^i_{t+j}$ conditioned on the original history and all previously generated rollout steps. Each generated submission is evaluated by the grading environment to produce the outcome $\hat{o}^i_{t+j} = v_f^{(d^i)}(\hat{a}^i_{t+j})$, which is then appended to the context for subsequent predictions. Rollout terminates early if there is no corresponding ground truth student generation or if the model generates a fully correct solution.

Metrics. We report three complementary metrics averaged across all predictions. First, **coverage** measures the proportion of ground-truth student submissions with model predictions. Coverage is less than 1.0 when models prematurely submit a correct solution (at step k where $v_r^{(d^i)}(\hat{a}^i_{t+k}) = 1$) while the student has not yet finished ($v_r^{(d^i)}(a^i_{t+k}) < 1$), a known challenge in student simulation [27]. For matched pairs where models did generate, we evaluate generation quality using two metrics: (1) **CodeBLEU** [34], measuring token-level syntactic and semantic similarity [15, 13, 24]; and (2) **grade proximity**, computed as $1 - |v_r^{(d)}(\hat{a}^i_{t+j}) - v_r^{(d)}(a^i_{t+j})|$, where higher values indicate closer functional alignment. These quality metrics are computed only on matched pairs where models did generate, to avoid biasing results against models that correctly stop at perfect grades. Conversely, this means models with different coverage levels have their quality metrics computed on different susbet of predictions, which should be kept in mind when comparing across methods. To assess robustness over rollouts, we also report **average degradation** Δ for each metric, which we compute as $\Delta m = \frac{1}{K-1} \sum_{k=2}^{K} (m_k - m_1)$, where m_k denotes metric performance at rollout step k and $K = 5$. More negative values indicate faster degradation from the first step.

6. RESULTS

Table 1 summarizes our training and test split statistics. Table 2 reports coverage and generation quality metrics averaged across all rollout steps. Figure 1 details performance at each rollout step, and Figure 2 illustrates how model-generated grades evolve compared to students ground truth grades. We highlight several key findings below.

Table 1: FalconCode dataset statistics. Summary of training and test splits. #Traj: total trajectories; #Stud: unique students; #Succ/#Fail: trajectories with final grade 100%/below 100%; #Asg: unique programming assignments; Avg. Len: mean submissions per trajectory;

Split	#Traj	#Stud	#Succ	#Fail	#Asg	Avg. Len
Train	1762	448	1712	50	17	22.4
Test	1000	384	981	19	15	20.1

Table 2: Rollout performance metrics. Legend: Cov (Coverage), GP (Grade Proximity), CB (CodeBLEU). Metrics averaged across k=1 to k=5 steps ahead, with degradation (Δ) showing the average drop from k=1 to k=2..5. Negative Δ values indicate performance worsens over longer rollouts. Bold: best performance within each model.

		Average			Degradation		
Model	Method	Cov	GP	CB	ΔCov	ΔGP	ΔCB
Qwen3-4B	BASE	0.528	0.690	0.491	-0.640	**0.278**	**-0.063**
	PARA	0.918	0.763	0.695	-0.118	-0.071	-0.137
	SFT	0.922	0.782	**0.704**	-0.107	-0.060	-0.138
	DPO	**0.982**	**0.797**	0.700	**-0.024**	-0.079	-0.137
	DAPO	0.859	0.781	0.700	-0.203	-0.068	-0.138
Qwen3-8B	BASE	0.570	0.733	0.581	-0.581	**0.287**	**-0.046**
	PARA	0.921	0.785	0.714	-0.112	-0.059	-0.121
	SFT	0.921	0.793	**0.718**	-0.110	-0.062	-0.126
	DPO	**0.957**	**0.796**	0.714	**-0.061**	-0.074	-0.129
	DAPO	0.919	**0.796**	0.709	-0.116	-0.078	-0.133
GPT-5-mini	BASE	**0.340**	**0.549**	**0.433**	**-0.910**	**0.184**	**-0.078**

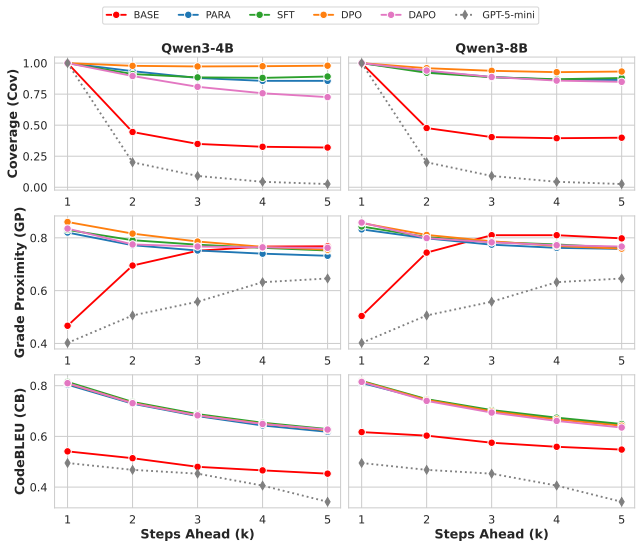

Figure 1: Performance across rollout steps. Coverage (top), Grade Proximity (middle) and CodeBLEU (bottom) as a function of autoregressive steps ahead (k=1 to k=5).

Prompted baselines cannot simulate realistic student behavior. BASE Qwen models achieve substantially lower coverage (0.528 for 4B, 0.570 for 8B), grade proximity (0.690, 0.733), and CodeBLEU (0.491, 0.581) than any fine-tuned model. GPT-5-mini performs worst overall, with a coverage of only 0.340 and grade proximity of 0.549. Its low coverage indicates that it frequently generates fully correct solutions that terminate trajectories after one or two steps, while its low CodeBLEU (0.433) confirms that the code it does produce has little resemblance to student submissions. Interestingly, BASE Qwen models outperform GPT-5-mini, possibly because their smaller capacity leads to genuine mistakes that incidentally resemble student errors, whereas GPT-5-mini's stronger coding ability defaults to expert-like solutions despite the explicit personification prompt.

Environment feedback improves student simulation. SFT performs as well as or better than PARA on all three metrics for both models (Table 2). The margins are modest but the pattern is consistent. This is notable because PARA has a structural advantage: without environment feedback in the context, it can fit more prior student submissions within the same token budget. Despite this, environment feedback proves more informative than additional code history. We hypothesize that earlier submissions, particularly from already-passed test stages, carry diminishing signal about the student's current debugging strategy, whereas grader feedback directly conditions the next revision.

Offline preference optimization yields the strongest results. DPO achieves the highest coverage across both model sizes (0.982 for 4B, 0.957 for 8B), producing valid code at more rollout steps than any other method. It also achieves the highest grade proximity for 4B (0.797 vs. 0.782 for SFT). SFT achieves slightly higher CodeBLEU (0.704 vs. 0.700 for 4B; 0.718 vs. 0.714), although this gap may partly reflect DPO's higher coverage: by generating at more rollout steps, DPO is evaluated on a broader and likely harder subset of predictions. DAPO shows mixed results: it matches DPO on grade proximity for 8B but achieves the lowest coverage among fine-tuned models on 4B (0.859), and does not consistently improve over SFT.

Performance over steps and trajectory position. Looking at Figure 1, BASE model coverage drops sharply ($\Delta = -0.640$ for 4B, -0.581 for 8B), as they frequently generate solutions that terminate the trajectory prematurely. Trained models degrade less, with DPO maintaining the highest coverage throughout (-0.024 for 4B, -0.061 for 8B), while DAPO coverage reduces more substantially over time (-0.203 for 4B). All fine-tuned models exhibit similar grade proximity degradation across rollout steps, with drops of approximately 0.06–0.08 from k=1 to k=5. The pattern over size is nuanced: for the 4B model, PARA degrades faster than SFT on grade proximity (-0.071 vs. -0.060), but for 8B, PARA degrades the least (-0.059) while preference-optimized models degrade the most (DPO: -0.074, DAPO: -0.078). Despite this, DPO maintains a higher absolute grade proximity compared to PARA at every rollout depth. Figure 2 shows that DPO-trained models most closely follow real student grade progression throughout normalized trajectories. DAPO models in contrast struggle to track students progressions. BASE models exhibit the opposite pattern: their grade proximity *improves* over rollout steps (+0.278 for 4B, +0.287 for 8B), and GPT-5-mini shows the same trend (+0.184). Figure 2 reveals an interesting pattern: untrained models generate solutions that achieve similar grades independently of trajectory position. We hypothesize that these models attempt to generate correct solutions, rather than adapting to the student's current progress. The difference is that GPT-5-mini largely succeeds, producing near-perfect grades throughout, while BASE Qwen models fail enough test cases that the corresponding grades happen to align with students grades at later trajectory positions. Neither reproduces the progressive improvement characteristic of real students. CodeBLEU shows more uniform downward trends across all trained models (≈ -0.13), suggesting that syntactic divergence accumulates at a similar rate regardless of training method. BASE model CodeBLEU remains comparatively stable (-0.063 for 4B, -0.046 for 8B).

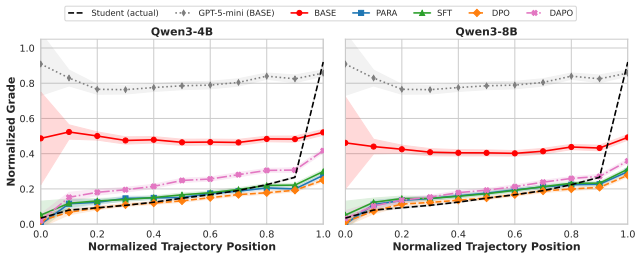

Figure 2: Grade progression across normalized trajectory position. Comparison of predicted grades between artificial student models and real students (black dashed, the average). The x-axis represents normalized position (by length) within a student's problem-solving trajectory (0 = start, 1 = end). Shaded regions indicate 95% confidence intervals. The ground truth line does not reach 1.0 as some students failed. The abrupt jump reflects the proportion of students who resolve multiple failing test cases in a single revision.

7. CONCLUDING DISCUSSION

Our experiments show that conversational serialization of student–environment interactions, combined with preference optimization, produces artificial students that more closely track real learners' debugging behavior than prompted baselines and models trained without feedback. Performance improvements compared to baselines are consistent in direction across both model sizes and all rollout steps. We believe coverage and grade proximity are particularly important dimensions for student simulation: models that generate code at every trajectory step, passing and failing the same tests at the same stages as real students, capture the incremental nature of real problem-solving more faithfully than models optimizing for surface-level code similarity alone. Among our findings, offline preference optimization via DPO provides the largest gains on these dimensions, achieving the highest coverage and grade proximity across both model sizes. Online preference optimization (DAPO) on the other hand does not consistently improve over SFT. We hypothesize that DAPO's weaker results may stem from (a) our computational constraint of sampling only 2 prefixes per trajectory compared to DPO's exhaustive coverage, and (b) the absence of chain-of-thought reasoning [47] prior to code generation, which online methods typically rely on for effective optimization. Our results thus suggest that without explicit reasoning traces, offline methods may remain more practical than recent online alternatives for student simulation.

While our experiments focus on within-assignment simulation, we hope the proposed framework will support several existing research directions.

Bridge with knowledge tracing and tutoring. Knowledge tracing (KT) models estimate a learner's latent proficiency across assignments, often predicting whether a student will solve a future task on the first attempt. Our framework operates at a complementary granularity: modeling the fine-grained debugging steps and intermediate attempts that precede success within a single task. We envision connecting these two levels by using cross-problem KC estimates as conditioning inputs to our simulation prompt [14], allowing our artificial students to exhibit more realistic learner behavior.

Bridge with tutoring. Moreover, our conversational serialization treats the automated assessment system as a dialogue partner that provides summative feedback. This is structurally identical to how a tutor agent would interact with a student. By representing student–environment interactions in this format, we could seamlessly extend sequences to include student–tutor exchanges, combining debugging traces with tutoring interactions [2] in a single sequence. This opens several directions: our models could be adapted to predict student success conditioned jointly on debugging attempts and tutor exchanges [37], or integrated into conversational knowledge tracing frameworks [36]. More broadly, artificial students trained with our approach could serve as scalable simulators for reinforcement-learning–based tutor training [12], where student success provides a training signal of tutoring strategy effectiveness.

Limitations. Our work is not free of limitations. We experimented with a single Python programming dataset and one model family across two sizes. Validation on additional datasets from different institutional contexts (with different autograder feedback styles) and programming languages is needed. Our evaluation data is heavily skewed toward successful students: 95% of trajectories end with a perfect score, meaning our results primarily reflect simulation quality for learners who ultimately succeed. This skew is partly inherent to programming courses, where most students eventually pass [45] and those who do not often abandon the course entirely [4, 20]. However, struggling students are precisely those most in need of intervention; modeling their behavior, including trajectory abandonment, remains important future work. We also report results using greedy decoding on a single semester of test data without statistical testing; evaluating under varied sampling strategies and data splits would strengthen confidence in our findings. Finally, while our metrics demonstrate that models replicate student grade trajectories and code similarity, one needs to validate whether these new artificial students will be effectively useful for the downstream applications we motivate, such as tutor training or intervention testing. Establishing this educational validity is important future work.

Future work. Beyond addressing the highlighted limitations, there are three direct next steps for student simulation. First, we will explore agent-based artificial students equipped with execution, submission, and editing tools, mirroring the interactive environments real students use when programming. Second, we will improve our online preference optimization method. GRPO-style methods are known to improve model performance when elicited to produce chain-of-thought reasoning. By prompting models to generate explicit student-like thought traces in between tool operations, we hope to improve such models' ability to follow students' processes while potentially yielding post-analysis insights into why students code the way they do. Lastly, we will explore methods to address the challenge of efficiently integrating students' prior history (i.e., their attempts at prior assignments) to enable better personalization.

ABSTRACT

Student questions provide a vital signal of how learning unfolds, yet the nature of these questions varies systematically across delivery media. We analyze student help-seeking behavior across two contrasting lecture environments: a synchronous, public Q&A channel where students compete for limited "fixed-time" airwaves, and an asynchronous, private AI lecture support tool that supports "flexible-time" engagement. We introduce an automated, human-validated labeling scheme to characterize over 4,500 student questions across three dimensions: intent type, reasoning explicitness, and confidence. Our application of this scheme suggests that while synchronous channels seem to reinforce a fixed-time/variable-learning bottleneck, the asynchronous medium is more consistent with a flexible-time/fixed-learning model. When inquiry is decoupled from the live lecture stream, the asynchronous channel is associated with denser, more conversational question streams (1.93 turns vs. 1.06 on average) and a significant increase in definition-oriented question types. We show that medium structure appears to meaningfully shape the length and volume of student questioning, shifting question-asking from survival in a live queue toward more iterative conceptual engagement.

Keywords

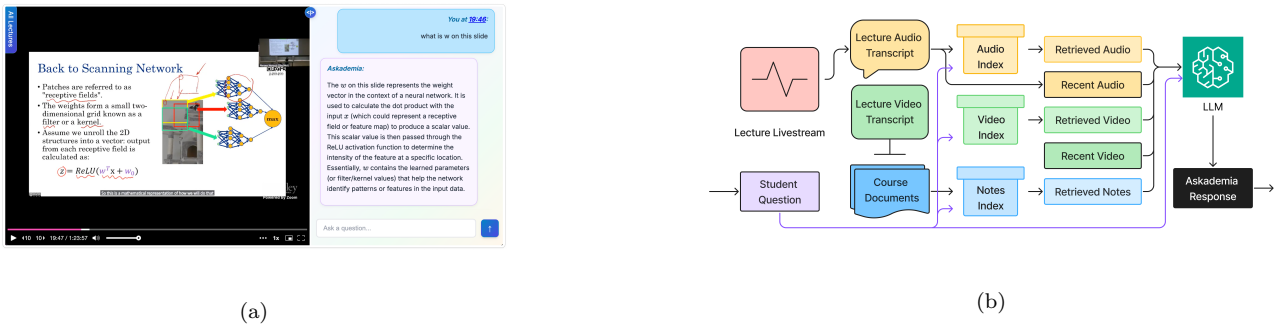
Question-Answering, Lecture, Educational Technology

1. INTRODUCTION

Student questions offer a direct window into how learning unfolds. They reflect what students find confusing, what they believe matters, and what they feel comfortable admitting they do not understand. In large classes, where instructors and Teaching Assistants (TAs) cannot engage deeply with every student in real time, the questions students ask become a practical signal of where support is needed.

A useful lens for thinking about lecture support is the contrast between *fixed-time* instruction and *self-paced* learning time. Traditional lectures largely follow a fixed schedule, whereas students vary widely in how much time and clarification they require to reach the same level of understanding. Prior work argues for shifting educational experiences toward more flexible time infrastructures to support consistent learning outcomes across students [6, 7, 8]. This framing is often discussed in the context of formative and summative assessments, but it also applies naturally to lecture support. When time is fixed and attention span is limited, students may ask fewer questions, ask different types of questions, or avoid asking altogether; when time is flexible and the interaction is private, students may ask clarification and follow-up questions, watch the lecture in multiple sessions, and pursue understanding iteratively.

At the same time, the conditions under which students ask questions are changing quickly. AI-powered education tools are now widely used alongside traditional course channels such as office hours, discussion forums, and live lecture Q&A. These tools can scale access to help, but they also change basic properties of help-seeking: who students believe is answering their question, whether questions are public or private, how easy it is to ask follow-up questions, and whether students can pause and rewind the material while forming their question. As a result, the questions instructors observe may differ not only because students need help with different concepts, but also because the medium may shape what they choose to ask and how they express it.



In this paper, we study student information-seeking behavior across two lecture support media with contrasting structures. The first is a synchronous, public live lecture Q&A channel (moderated on Slido[1]), where students post questions that are visible to peers and expect a TA response within the constraints of lecture pacing and a shared queue. The second is Askademia [20], an asynchronous, private AI lecture support tool used while students watch recorded lectures. In this medium, students know an AI system will an-

Figure 1: (a) Askademia interface embedded in the lecture experience, enabling grounded question asking at specific lecture moments. (b) Askademia system pipeline for retrieving relevant context and generating grounded responses.

swer them, their questions are private, and they can pause, rewind, and ask multiple follow-up questions.

Askademia [20][2] is a context-aware question-answering tool developed and deployed at UC Berkeley. It processes lecture video and audio to produce searchable, textual representations of spoken utterances and on-screen text, retrieves relevant lecture moments and course notes based on a student question, maintains a sliding window of recent context, and uses a Large Language Model (LLM) to generate a grounded response (Figure 1b). The student-facing interface (Figure 1a) supports questions tied to specific lecture moments and enables rapid back-and-forth as students refine their questions while reviewing material.

We ask essential questions with important implications for both tool design and instructional practice:

RQ1 How do student questions differ between fixed-time, synchronous TA lecture Q&A and self-paced, asynchronous AI lecture support in terms of what students ask and how they express reasoning and confidence?

RQ2 How do question volume, timing, conversation length, and user activity differ across media, and what do these differences suggest about how students use each channel?

To investigate these questions, we introduce a labeling scheme that characterizes questions along three dimensions: (1) intent type (logistical, definition-oriented, analytical, and meta), (2) whether students explicitly or implicitly express their reasoning process, and (3) confidence (neutral, high confidence, and low confidence). We apply this scheme at scale to quantify differences in question content and expression across synchronous and asynchronous media. Finally, we compare question volume, conversation length, and user activity to characterize how question flow differs between live public Q&A and private asynchronous AI support.

2. RELATED WORK

2.1 Student Help-Seeking and Behavior

Student questions are shaped by more than content difficulty: help-seeking is tied to motivation, confidence, and perceived cost (e.g., effort, embarrassment, or fear of asking a "bad" question) [4]. Digital learning tools aim to lower these barriers and increase engagement by changing how and when students can ask for help [2, 3]. As LLM-based tools become more common for student learning support, recent studies emphasize that tool choice and context affect how learners seek help, including whether students externalize uncertainty, ask incremental clarifications, or adopt different strategies [12, 27, 5]. Our work compares how question characteristics shift between a synchronous public medium and an asynchronous private AI medium.

2.2 Lecture-Time and Course Q&A Channels

Large courses face a bottleneck: questions arrive continuously, but instructional bandwidth and time are limited [15, 17]. This motivates the design of course Q&A channels to manage scale, redundancy, and timeliness. Tools such as Slido impose distinctive constraints: questions are posted in a shared, public queue, and participation is shaped by lecture pacing and limited response capacity. Prior work in computing education documents both the promise and the practical friction of these at-scale question channels [15, 17]. Our comparison between synchronous, public lecture Q&A and asynchronous, private AI-enabled Q&A examines how these constraints are reflected in the questions students ask and how they participate.

2.3 Retrieval-Augmented and Multimodal AI Course Assistants

Recent educational assistants use LLMs to support student questions in course environments [28, 23, 9]. These systems are often deployed as virtual assistants to reduce logistical overhead and scale students' access to course support [15, 17, 11, 14]. They have become more contextualized and course-aligned using Retrieval-Augmented Generation (RAG) [13, 18, 1]. In parallel, lecture and video tooling have explored how to represent what happened in a lecture through transcripts and visual signals [16]. More recent multimodal methods improve robustness by aligning noisy Automated Speech Recognition (ASR) with visual context [24] and by incorporating video frames into scientific transcription [26]. Broader progress in multimodal and visual question answering further motivates treating lecture content as a multimodal substrate that can be queried [25, 10].

[2] https://www.askademia.org/

2.4 Analyzing Student Questions

Prior work uses qualitative coding of question intent types and discourse features, paired with reliability checks, as well as automated NLP approaches for categorization at scale. With the growth of LLMs, prompting-based labeling has become a practical way to approximate consistent categorization over large corpora of student discourse [27, 5]. Studies of AI course support also highlight risks around consistency, misalignment with instructional norms, and equity when scaling support [19, 9]. Our paper introduces a compact labeling scheme and applies automated, human-validated labeling to compare patterns across synchronous, public Q&A and asynchronous, private AI Q&A. Rather than evaluating answer quality or system components, our work asks how information-seeking behavior differs when students interact with an AI system privately and asynchronously, compared with a synchronous, public channel.

3. METHODS

3.1 Lecture Support Media

We study student information-seeking behavior in two large upper-division Computer Science (CS) and Data Science (DS) courses at the University of California, Berkeley, with a combined enrollment of around 1,500 students. In both courses, students could ask questions via synchronous and asynchronous channels. In the synchronous medium, students posed questions electronically to TAs during the lecture via Slido. Students contributed to a shared channel of questions, where they could see contributions from other students and TAs. Each lecture lasted approximately 80 minutes, and students could attend live in-person or via Zoom. In the asynchronous medium, students directly asked Askademia while watching recorded lectures on the Askademia platform. Each student contributed to an individual channel of questions, could pause, rewind, and speed up lectures, and could not see other students' conversations.

Per IRB approval for this study,[3] All data included in our analyses were collected and used in accordance with the approved protocol. This protocol covered both sources of student questions considered in our analyses, namely synchronous questions submitted through Slido during lecture and asynchronous questions submitted through Askademia. Our analysis includes **992** synchronous questions (607 CS, 385 DS) asked via Slido across 56 lectures and **4,511** (2,721 CS, 1,790 DS) asynchronous questions from Askademia users who consented to the use of their anonymized questions for research.

3.2 Observable Characteristics

3.2.1 Labeling Scheme

Two annotators conducted exploratory analysis on a random sample of 100 questions and developed a three-dimensional labeling scheme: **Intent Type**, **Reasoning Process**, and **Confidence**. We treat this as a compact, study-specific framework rather than a standardized educational taxonomy. We selected these dimensions because they capture both what students ask and how they ask it, which aligns with our goal of comparing question behavior across synchronous and asynchronous media. The labeling criteria are described below:

[3]This study was approved by the UC Berkeley Institutional Review Board under Protocol ID 2025-09-18906.

Table 1: Representative Examples of Question Labels

Label	Example
	Intent Type
Logistical	"Which textbook are we using?"
Definition	"What is a partial derivative"
Analytical	"Why square the residuals instead of taking an absolute value?"
Meta	"draw me a picture"
	Reasoning Process
Implicit	"Does the denominator of softmax function include the numerator?"
Explicit	"Why does high bias matter? can't we just add in a factor to account for it and try and min the variance?"
	Confidence
Low	"Im confuse, if i have y = mx + b, and i have y(x) = 0, then won't it be 0 = mx +b and thus one solution?"
Neutral	"How is clustering different from classification?"
High	"Bias is the expected difference between predicted and actual though right"

- **Intent Type:** The type of content. Logistical pertains to course operations and policies; Definition pertains to identifying course concepts; Analytical pertains to explaining course concepts in depth; and Meta refers to all questions unrelated to the course. Questions could be labeled as both Analytical and Definition.
- **Reasoning Process:** Whether a student expresses their reasoning process implicitly or explicitly. Explicit questions reveal a student's train of thought, while Implicit questions do not.
- **Confidence:** How confidently a student asks a question. Low-Confidence indicates confusion or skepticism; Neutral questions are asked without uncertainty or over-sureness; High-Confidence questions are typically requests for confirmation and validation.

Two annotators labeled a random sample of 30 questions from both modalities. Initial inter-rater reliability was 60% for intent type, 93% for reasoning process, and 83% for confidence. For each question where there was disagreement, annotators discussed their decisions until an agreement was reached. Afterward, one of the two annotators labeled a random sample of 100 questions.

3.2.2 Automated Labeling

We developed an automated labeling system by prompt engineering GPT-4o [21] for classification. The LLM was provided with a labeling scheme and our set of 30 questions labeled by both annotators. We instructed the LLM to provide an explanation for each generated label, and used hyperparameter values of 0.1 for temperature and top-p, which control the creativity of model responses. When evaluated on our test set of 100 labeled questions, our classifier achieved 81%, 94%, and 83% agreement with human labels for intent type, reasoning process, and confidence, respectively. We used this LLM classifier to label all student questions.

3.2.3 Question Length and Sentiment

We measured length and sentiment as additional characteristics of student questions. To determine sentiment, we used pysentimiento [22], a transformer-based library for sentiment analysis. Each question was classified as Positive, Negative, or Neutral.

3.3 Question Volume and Frequency

We recorded the number of questions per lecture in each medium, the conversation lengths, and the total number of questions asked by each unique user. In the synchronous medium, each question opens a thread where students can post follow-up questions and receive additional TA responses; conversation history is measured as the number of student-TA turns within that thread. In the asynchronous medium, information seeking is continuous in a chat-like interface; we treat a question as a follow-up if it is asked within one minute of a previous question. We selected this one-minute window as a simple heuristic to capture short bursts of back-and-forth clarification in a chat setting. To reduce sensitivity to this choice, we also report a stricter alternative in which follow-up questions are linked only when they share the same lecture timestamp, indicating that a student paused the lecture video to engage further with a specific moment in the recording. We further analyze timestamp-anchored interaction patterns in the asynchronous medium, including clusters of questions asked at the same lecture timestamp and questions asked after rewinding the lecture.

4. RESULTS

4.1 RQ1: Question Content and Expression

We study how question content and expression differ across media by analyzing five characteristics: intent type, reasoning process, confidence, sentiment, and question length.

Table 2: Proportion of each intent type for questions asked in synchronous and asynchronous media, with p-values from a two-proportions z-test. Results are grouped by course.

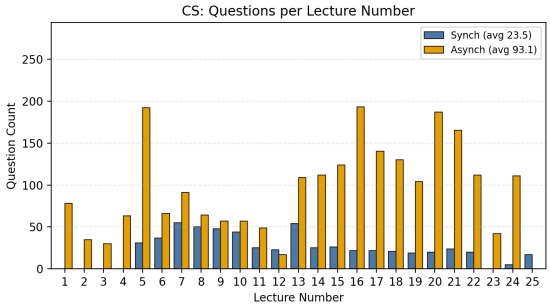
Intent	Course	Synch	Asynch	Diff	p
Logistical	CS	0.102	0.033	0.069	< 0.001
	DS	0.242	0.064	0.178	< 0.001
Definition	CS	0.245	0.402	-0.157	< 0.001
	DS	0.255	0.368	-0.113	< 0.001
Analytical	CS	0.616	0.513	0.103	< 0.001
	DS	0.475	0.423	0.052	0.062
Meta	CS	0.048	0.072	-0.024	0.029
	DS	0.047	0.153	-0.106	< 0.001

Intent type. Table 2 shows the proportion of each intent type for both media. Questions labeled as both Analytical and Definition contributed to proportion estimates for both categories. For both courses, the proportions of questions that were Logistical and Analytical were higher in the synchronous medium than in the asynchronous one. In comparison, for both courses, the proportions of student questions that were Definition and Meta were significantly lower in the synchronous medium than the asynchronous one.

Reasoning process. Across media, student reasoning patterns were similar. For the CS course, 10.87% of questions expressed explicit reasoning in the synchronous medium compared to 11.44% in the asynchronous one. For the DS course, 8.31% of questions expressed explicit reasoning in the synchronous medium compared to 9.05% in the asynchronous one. These differences were not statistically significant.

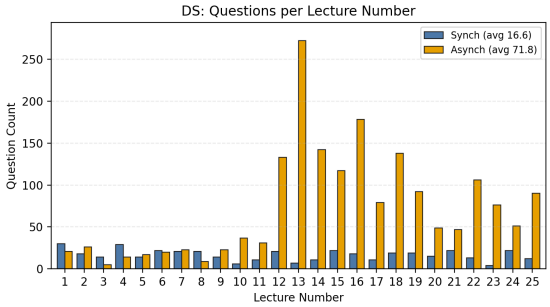
Confidence. For the CS course, the proportion of high-confidence questions was lower in the synchronous medium (0.04) than in the asynchronous (0.09), with $p < 0.001$. Similarly, for the DS course, the proportion of high-confidence questions in the synchronous medium (0.021) was roughly half of that in the asynchronous (0.041), although this difference was not statistically significant. For low- and medium-confidence (neutral) questions, differences between media were marginal.

Sentiment. A higher proportion of questions in CS course expressed negative sentiment in the synchronous medium (0.11) compared to the asynchronous (0.075), with $p = 0.004$. However, the proportion of negative questions in the DS course was similar for both media, ranging from 0.119 in the synchronous medium to 0.111 in the asynchronous one. In only the CS course, a lower proportion of questions were neutral in the synchronous medium (0.885) compared to the asynchronous one (0.916) with $p = 0.014$. For positive questions, differences between media were not statistically significant in both courses.



Question length. We report results from a two-sample t-test. For the CS course, the mean question length was slightly greater in the synchronous medium (15.53 words) than in the asynchronous one (14.91 words). For the DS course, mean question length was significantly greater in the synchronous medium (16.15 words) than the asynchronous one (12.86 words), with $p < 0.001$.

4.2 RQ2: Question Volume and Frequency



To study how interaction modality shapes question flow, we compare synchronous in-lecture questions (Synch TA) with asynchronous questions (Asynch Askademia) along three timing/frequency dimensions: per-lecture volume, conversation structure, and per-user participation concentration.

Per-lecture volume. As shown in the Figure 2, Asynch Askademia consistently receives substantially more questions per lecture than Synch TA within each course. In the CS course, the mean questions per lecture was 93.12 (Asynch) vs. 23.52 (Synch), with median questions per lecture 91 vs. 22. In the DS course, mean questions per lecture were 71.84 (Asynch) vs. 16.64 (Synch), with medians 49 vs. 18.

Figure 2 also shows a noticeable mid-semester surge in asynchronous question volume, aligning with the midterm period when students revisit past material. In contrast, Synch TA volume shows a flatter pattern over the same span, with no comparable spike. This divergence suggests that stu-

(a) CS course

(b) DS course

Figure 2: Distribution of questions per lecture, Synch TA vs. Asynch Askademia, shown separately for the CS and DS courses.

dents used the asynchronous medium for extended review and studying, while the live Slido channel may be used more for immediate, in-the-moment clarifications.

Conversation structure. Asynchronous questions are submitted with an associated lecture timestamp, allowing us to characterize how students concentrate questions around particular moments. We define a "paused" conversation as a set of two or more questions, with the same lecture timestamp, from a single student. Across **4,511** asynchronous questions, **2,300** are part of a "paused" conversation (51.0% of all Asynch questions). This behavior has no direct analog in the live TA setting, but highlights a distinct form of demand: students often want to pause at a specific point in the lecture and ask several tightly coupled questions to reach understanding, reinforcing the value of an always-available support channel anchored to fixed points in time.

We also observe **230** "rewind" questions, in which a student asks a question at an earlier lecture timestamp after having asked a question later in the lecture. This further supports the interpretation that asynchronous help-seeking is embedded in non-linear lecture consumption: students pause and move back and forth through the recording, revisiting earlier moments to resolve confusion when it arises.

Figure 3 indicates longer conversations in the asynchronous medium. Mean conversation length is 1.93 (Asynch) vs. 1.06 (Synch). This remains true under a stricter follow-up definition that only links questions with the same lecture timestamp (i.e., "paused" conversations), rather than linking questions within 60s; the asynchronous mean conversation length is still higher (1.54 vs. 1.06), with $p < 0.001$. Asynchronous conversations more often extend beyond single-question interactions, whereas synchronous interactions are predominantly one-shot. This pattern is consistent with students treating the asynchronous tool as a conversational agent: they can ask an initial question, read the response, and then refine or extend their inquiry without worrying about taking up public airtime or interrupting the lecture flow.

Participation concentration. Figure 4 indicates substantially more active users in Asynch Askademia than in the Synch medium. In the Synch medium, only 31 users asked

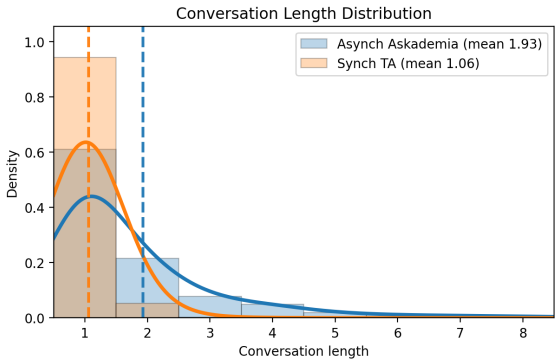


Figure 3: Conversation-length distribution (1 = no follow-up, 2 = one follow-up, etc.)

at least 5 questions throughout the whole semester, whereas in Asynch, 121 users asked at least 5 questions—almost **4**× as many relatively active users. The percentile markers in the figure show the same pattern of heavier engagement in Asynch: Asynch has p90 = 48.0 and p99 = 221.5, compared with Synch, which has p90 = 5.2 and p99 = 27.9. The Synch distribution is visibly concentrated in the lowest bins, suggesting that most students either ask a few questions or rely on the shared channel rather than repeatedly posting. In contrast, Asynch exhibits a much longer right tail, consistent with many more students returning to the tool across the term and using it as a sustained support resource while learning at their own pace. This broader set of active users suggests that a private, self-paced medium may extend meaningful information seeking beyond a small set of highly vocal students who participate in public live Q&A.

5. DISCUSSION

Labeling as a lens on medium differences. Our framework reveals systematic shifts in the types of uncertainty students externalize. The synchronous TA channel contained a larger share of logistical and analytical questions. In contrast, the asynchronous AI channel contained more definition-oriented and meta questions, along with a higher share of high-confidence, confirmation-style questions. One possible interpretation is that students sometimes used the asynchronous tool to validate their understanding of lecture

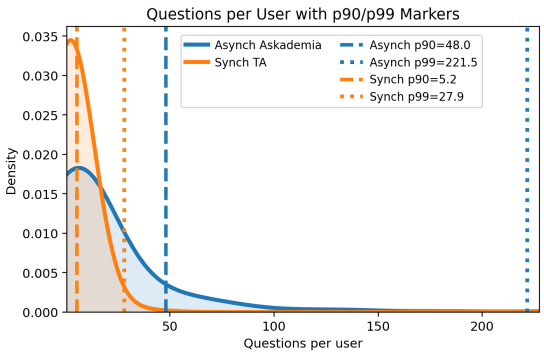

Figure 4: Distribution of the number of questions per user.

concepts rather than only to seek first-pass explanations. Reasoning explicitness remained low in both settings, suggesting that the two media differed more in what students asked than in how they articulated their reasoning. These label distributions suggest that the medium may shape which types of questions are easier to ask, socially appropriate, and likely to receive a useful response.

Participation and timing. Beyond content, the two media differed in scale and participation. The asynchronous medium received substantially more questions per lecture, showed stronger temporal variation, and was used repeatedly by a broader set of students. In contrast, the synchronous TA channel was more concentrated among a smaller group of frequent question askers. While we cannot attribute these differences to a single cause, they are consistent with medium affordances that may reduce barriers to asking, alongside other possible influences such as self-selection into support channels, differences in student expectations, and variation in when students seek help. Though we did not directly test this, shorter asynchronous questions may also align with students using the tool for brief, iterative clarification rather than composing longer, standalone questions. Similarly, some asynchronous questions may have been asked during review rather than first exposure, whereas synchronous questions were asked while students encountered the material live. If so, some observations may reflect not only channel structure but also differences in when students sought help.

Fixed-time instruction, variable-time learning. "Paused" conversation patterns, "rewind" questions, and a higher rate of multi-turn interaction in the asynchronous setting highlight a mode of help-seeking that is difficult to realize in live lecture Q&A. Students appear to pause at specific moments, ask clusters of related questions, and iteratively refine understanding before proceeding. They also sometimes return to earlier lecture moments after moving later in the recording. Unlike the synchronous setting, where questions must be posed under real-time lecture constraints, the asynchronous medium decouples help-seeking from the live flow of instruction. Students can spend variable time at moments of confusion while the instructional timeline remains fixed in the background. This supports a pause-and-repair workflow without the pacing costs of interrupting a live lecture, which may contribute to both longer conversation structure and higher overall demand.

These results motivate treating Q&A channels as part of the instructional environment rather than interchangeable interfaces. Overall, the medium structure was associated with differences in what students asked, who participated, and whether help-seeking took the form of a one-shot request or a more iterative process. Future work should test the generalizability of these patterns and connect medium-specific traces, including confirmation-heavy and "paused" usage, to downstream measures of engagement and learning.

Limitations. Our analysis is limited by the covariates available in the dataset. We did not have access to student-level background measures such as prior GPA, demographics, attendance mode, or prior usage history, nor to course-level covariates such as lecture difficulty or assessment timing. As a result, we could not adjust for potentially important differences in which students used each support channel, and unmodeled confounders, including self-selection and differences in when students chose to seek help, may also contribute to the patterns we observe.

More fundamentally, our comparison does not isolate the effect of any single factor. The two channels differ simultaneously along structural dimensions such as synchronicity, privacy, responder identity, and lecture-viewing context, as well as harder-to-measure sociotechnical ones such as students' familiarity with and acceptance of AI tools, their expectations about response quality and authority, their perceptions of the AI's institutional role, and the social costs of asking. The observed differences may therefore reflect a bundle of channel affordances, interaction norms, and user expectations rather than the independent effect of the interaction medium alone. Our findings are also drawn from two computing courses in one institutional context, which may limit generalizability. Future work with richer student- and course-level data, and designs that vary these features more independently, could better disentangle these explanations.

6. CONCLUSION

Our findings suggest that the transition from synchronous, human-led Q&A to asynchronous, AI-driven support is associated with a shift from fixed-time/variable-learning to flexible-time/fixed-learning. In traditional synchronous lectures, the rigid temporal structure may function as a bottleneck, placing students in a competitive, public environment where learning remains "variable" for those who cannot keep pace with the live stream. In contrast, the asynchronous medium supports "flexible time" when inquiry is decoupled from the lecture's live delivery, allowing students to treat conceptual mastery as a "fixed" goal. The asynchronous medium is associated with students engaging in denser, more iterative, and definition-oriented dialogues, which may reflect lower social costs and fewer time constraints. These patterns suggest that medium structure may support a more equitable instructional model, in which time spent is the variable and depth of understanding is the constant.

ABSTRACT

Early identification of students who may struggle to learn from practice could enable timely instructional support. This study investigates whether keystroke dynamics during initial problem-solving attempts can signal subsequent knowledge gain in mathematics. We analyzed keystroke patterns from students' first two problems following instruction on a skill, examining associations with knowledge gain operationalized through Bayesian Knowledge Tracing. Students who ultimately learned more exhibited systematically different early behaviors: slower, more variable typing with greater revision activity. Effect sizes ranged from small to moderate (Cliff's $\delta = 0.15$–0.38), with timing features showing strongest associations. Machine learning models achieved modest but above-chance predictive accuracy (regression: RMSE = 0.36, $r = 0.42$; classification: AUC-ROC = 0.68, balanced accuracy = 0.67). While individual keystroke features explained limited variance (3.6–11.6%), results suggest that fine-grained behavioral traces from students' earliest practice attempts may provide meaningful early signals about learning trajectories, potentially enabling proactive instructional adaptation before patterns of persistent struggle emerge.

Keystroke dynamics, Knowledge gain, Early prediction

1. INTRODUCTION

Intelligent tutoring systems (ITSs) have demonstrated the potential to significantly improve student learning outcomes [14]. By personalizing instruction and feedback, these systems can help learners acquire new knowledge and skills more effectively than traditional one-size-fits-all instruction. However, an important goal for such systems is not merely to optimize immediate performance (e.g., getting questions correct), but to ensure that students are actually learning—making durable knowledge gains [13]. In practice, a correct answer does not always equate to genuine understanding. For instance, some learners might arrive at correct answers by rote application of superficial strategies, such as relying heavily on hints, pattern matching, or completing problems through trial and error, without developing a deeper understanding of the underlying concepts or procedures. Such behavior may lead to high performance in the short term while yielding smaller gains in robust, long-term learning. This contrast between performance and learning highlights the need for adaptive platforms that focus on cultivating knowledge growth (e.g., long-term retention and transfer; [13]), rather than merely supporting immediate problem correctness.

A related challenge for intelligent tutoring systems concerns when different kinds of instructional decisions should be made. Most ITSs already provide rapid, fine-grained support at the inner-loop level—for example, responding immediately to an incorrect step with hints or feedback [17]. This form of in-the-moment guidance is often effective, but it is not always sufficient. Some students fail to make substantive progress despite repeated inner-loop assistance, resulting in wheel-spinning, where they continue working over a substantial time without moving closer to mastery [4]. Addressing such situations can require intervention by a teacher or outer-loop decisions by the learning environment [17], such as providing support with prerequisite skills. In most existing systems, however, these types of interventions only occur when the instructor realizes that a student has been struggling for quite some time. Although prior work has explored early prediction of eventual wheel-spinning [15, 5, 18], these predictions still rely on several problems of student interaction. This raises a natural question: can the need for deeper support be inferred even earlier—during a student's initial encounters with a skill? If so, an ITS could begin adapting instruction not after prolonged difficulty, but from the very beginning of work on the skill.

Early prediction of learning outcomes requires access to in-

formation that reflects how students engage with tasks as learning unfolds. Beyond final answers, fine-grained interaction traces—such as timing, attempts, and patterns of interaction—can reveal how a student is approaching a problem in real time [12]. Keystroke-level information provides even finer-grained detail, capturing the exact sequence and timing of keys pressed as a student constructs a response. This level of detail has been argued to shed light on the cognitive and metacognitive processes involved in problem solving [9]. For example, long pauses before initiating a response may reflect planning or recall, while rapid sequences of edits and deletions may indicate uncertainty or guess-and-revise strategies. In this sense, how a student types may provide insight into hesitation, confidence, and strategy use—factors that are closely related to learning [1, 16].

Building on this motivation, prior research in educational data mining has explored early prediction of learning outcomes using students' initial interactions [4, 6, 15, 5, 18]. These studies draw on data such as keystrokes, clickstream logs, and tutor transaction sequences to anticipate short- and long-term outcomes. For instance, Beck and Gong's work on wheel-spinning examined a student's first few attempts on a new skill to identify students unlikely to attain mastery, flagging those at risk of continuous failure and prompting possible changes in learning support. Other studies have focused on course-level or test outcomes. Casey [6] developed classifiers to detect at-risk programming students early in the semester; the inclusion of keystroke features improved the model's ability to predict which students would not pass the course. Conijn et al. [7] examined keystroke logs from the beginnings of writing assignments to forecast final essay quality. While their predictive models only modestly outperformed baselines, they demonstrated the viability of using typing process data to identify students who might need writing support before the draft is completed. Researchers have also shown that even a short window of student activity can yield insight into far-future outcomes. Gao et al. [10] found that data from the first 2–5 hours of student usage of an educational game and an ITS provided a valuable signal about students' performance on end-of-year assessments months later. In their study, a machine learning model using only the initial few hours of log data was able to predict year-end test scores with notable accuracy, indicating that early behaviors encapsulate information about eventual learning results. Together, this body of literature illustrates the promise of early prediction: from fine-grained keystroke patterns to aggregated usage metrics, a range of early indicators have been leveraged to forecast outcomes such as course failure, essay scores, and standardized test performance.

While prior studies demonstrate that early interaction data, including keystrokes, can be informative for predicting later performance or task outcomes, they offer limited insight into whether such early behaviors relate to subsequent knowledge gain during skill practice. Work incorporating keystroke features has examined outcomes such as essay quality, programming performance, or mastery likelihood, rather than learning improvement across a sequence of problems. Consequently, it remains unclear whether keystroke behaviors observed during students' initial encounters with a new skill are related to how much they ultimately learn through continued practice. This gap matters because proactive support requires identifying not only students who struggle to answer correctly, but also those who make limited learning gains even when their early answers are correct.

To fill this gap, we address two research questions. First, how are students' early keystroke patterns during their initial encounters with a skill associated with subsequent knowledge gain? Second, to what extent can early keystroke patterns predict students' eventual knowledge gain on that skill? To investigate these questions, we analyze students' keystroke patterns from the first two problems of a skill and relate them to subsequent knowledge gain. Using Bayesian Knowledge Tracing (BKT), we operationalize knowledge gain as the difference between the student's BKT-estimated mastery level at the start and end of practice on a given skill. We employ both statistical analyses and machine learning approaches. We examine group differences in early keystroke features between high-gain and low-gain students, then train predictive models to assess whether early keystroke features contain a meaningful signal about students' eventual knowledge gain. One modeling task estimates the amount of learning a student will achieve, while a complementary classification task evaluates whether these early behaviors can distinguish students who ultimately show higher versus lower knowledge gains.

2. METHODS

2.1 Data

2.1.1 Source and Context

This study used de-identified data from an online mathematics learning platform with adaptive practice. Each topic begins with a short diagnostic assessment, after which students receive targeted instruction through worked examples and videos before entering the worksheet practice phase. We focus on this worksheet phase, where students independently solve problems using open-ended typed responses that generate keystroke sequences and timing information. All personally identifiable information was removed prior to data access. The final dataset comprised 19,155 fully matched student–question transactions, each representing a single practice problem.

2.1.2 Correctness Labelling

The worksheet data did not include correctness labels. To generate these at scale, we developed and validated an automated correctness labeler using GPT-4o, prompted to assess whether a student's response was mathematically equivalent to an expert reference answer under explicit equivalence rules (e.g., commutativity, numerical approximation, and formatting variations). Ground truth was established via double human annotation of 200 responses, yielding high inter-rater reliability ($\kappa = 0.95$); disagreements were resolved through social moderation. The automated labeler closely matched human judgments ($\kappa = 0.95$, precision = 0.97, recall = 0.95) and was subsequently used to label all 19,155 responses.

2.1.3 Keystroke Data and Feature Engineering

Each worksheet question answered generated a sequence of keystrokes and associated metadata, including information

Table 1: Example of selected columns from a single row of the raw data (← = left-arrow cursor movement; BKSP = Backspace).

Question	Input	Keystroke	Reference	Time(s)
2548 − 362	2186	← 218y BKSP 6	2186	167

Table 2: Features and their definitions.

Feature	Definition
Keystroke edit distance	Levenshtein distance between the full raw keystroke sequence and the final submitted answer.
Seconds per keystroke	Total time spent on the response divided by the total number of keystrokes.
Keystroke entropy	Shannon entropy of the keystroke sequence.
Correction density	Number of correction keys (Backspace, Delete) divided by log-transformed total time.
Correction proportion	Number of correction keys divided by total keystrokes.
Keystroke efficiency ratio	Final answer length divided by total keystrokes.
Average seconds between keys	Mean inter-keystroke time (seconds) for a question attempt.
Variation in seconds between keys	Standard deviation of inter-keystroke times (seconds) for a question attempt.

about time spent, editing actions, and overall input behavior. Table 1 illustrates an example of a single row of data showing the information captured for a student's response to a worksheet question. From these data, a set of features was derived to capture temporal, corrective, and compositional aspects of students' typing activity. Table 2 presents a detailed summary of all engineered features.

2.2 Analysis

2.2.1 Deriving Knowledge Gain from BKT

To quantify learning within each skill, we applied Bayesian Knowledge Tracing (BKT) [8] to students' sequential response data. BKT models student learning as a dynamic process within a Hidden Markov Model framework, where each student transitions between two latent states: not mastered and mastered across successive items answered within the same skill. While prior work has noted limitations in BKT's accuracy at predicting subsequent performance [11], we adopted BKT not for predictive accuracy but as a relative indicator of student mastery based on prior performance. For this purpose, it is useful that BKT provides a situation-independent estimate of mastery that does not incorporate item difficulty or information from other skills, unlike more recent knowledge tracing models. BKT's ability to account for guessing and slipping further supports its use for mastery estimation in this context. BKT parameters were fit using a Brute Force/Grid Search algorithm [3], with a minimum value of 0.01 applied to all probabilities and a maximum value of 0.3 imposed on guess and slip parameters to prevent model degeneracy [2]. The resulting parameter estimates were used to compute predicted probabilities of mastery for each student after each question. For each student–skill pair, we extracted the probability of mastery before any question was answered, $P(L_0)$, and after the final question, $P(L_T)$; knowledge gain was then defined as $P(L_T) - P(L_0)$. Positive values indicate increased mastery across practice, while negative values reflect performance below the initial estimate. To focus on skills where meaningful learning occurred, we retained only skills with an average gain greater than 0.1. These knowledge gain values served as the target variable for all subsequent analyses.

2.2.2 Data Preparation for Analysis

After retaining only skills with average knowledge gain above 0.1, the dataset was reduced from 19,155 to 1,212 transactions. To capture early engagement, predictors were computed from the first two questions per skill by averaging numeric features across those attempts. This two-question window balances early identification with robustness, avoiding reliance on a single initial response that may reflect task familiarization rather than learning difficulty. Applying this restriction yielded a final dataset of 232 student–skill records from 190 (unique) students across seven skills. The dataset includes all keystroke features in Table 2 and a continuous BKT-based knowledge gain label, which ranged from -0.41 to 0.99 ($M = 0.19$, $SD = 0.40$). For classification, 53% of observations fell above the median knowledge gain and 47% below, which we treat as proxies for successful and unsuccessful learning.

2.2.3 Exploratory Analysis

To investigate the relationship between early keystroke features and subsequent knowledge gain, we conducted a set of exploratory statistical analyses to characterize the nature and direction of these relationships. We tested for significant differences between students categorized as successful learners (knowledge gain at or above the skill-specific median) and unsuccessful learners (knowledge gain below the skill-specific median) using the Mann–Whitney U test. p-values were corrected for multiple comparisons using the Benjamini-Hochberg false discovery rate (FDR) procedure, and effect sizes were computed using Cliff's Delta. Following this group comparison, continuous associations between each keystroke feature and numerical knowledge gain were assessed using Spearman's rank correlation. To further explore these relationships, the data were divided into four quartiles of knowledge gain (Q1–Q4), allowing inspection of median keystroke feature values within each quartile and revealing progressive trends as knowledge gain increased. These analyses characterize individual feature–outcome relationships, while Section 2.2.4 evaluates their combined predictive power.

2.2.4 Predictive Modelling

To evaluate the predictive power of students' early keystroke patterns, we conducted two predictive modeling tasks: a regression task to predict the magnitude of knowledge gain and a classification task to identify whether learning outcomes were successful. All models were evaluated using five-fold cross-validation, stratified at the student level to ensure that data from a given student did not appear in both training and test sets within a fold. This approach prevents data leakage and supports generalization to un-

Table 3: Comparison of keystroke features between successful (S) and unsuccessful (U) learning groups via Mann-Whitney U test (group alpha = 0.05)

Feature	S_{Mdn}	U_{Mdn}	δ	p-value
average seconds between keys	1.15	0.62	**0.38**	< 0.001

seen students. Within each fold, hyperparameter optimization was performed on the training set to identify the best-performing configuration for each model.

The regression task aimed to predict the continuous value of a student's knowledge gain from early keystroke features, serving an exploratory purpose by modeling the relationship between keystroke behavior and learning magnitude. The evaluated models included Random Forest Regressor, Extra Trees Regressor, Decision Tree Regressor, Linear Regression, Ridge Regression, and M5Prime. Model performance was evaluated using linear correlation and root mean squared error (RMSE), capturing both the strength of association between predicted and observed knowledge gain and the magnitude of prediction error. All reported results were averaged across cross-validation folds. The classification task predicted whether a student's knowledge gain was above or below the median for a given skill. This task evaluates the practical diagnostic utility of early keystroke features for distinguishing between high-gain and low-gain learners, with implications for targeted intervention. The target variable was binarized relative to the median per skill to account for differences in difficulty across skills. Models evaluated included Logistic Regression, Decision Tree, Random Forest, RIPPER, and K*. Performance was measured using the Area Under the Receiver Operating Characteristic curve (AUC-ROC), the Area Under the Precision-Recall curve (AUC-PR), F1-score, standard accuracy (ACC), and balanced accuracy (BACC).

3. RESULTS

3.1 How is Early Keystroke Patterns associated with Knowledge Gain?

To understand the relationship between early keystroke features and knowledge gain, we began by comparing students classified as successful learners with their unsuccessful peers. The Mann–Whitney U test (with Benjamini–Hochberg correction) identified significant differences for all eight features (Table 3). Effect sizes (Cliff's Delta) ranged from 0.15 to 0.38, indicating small to moderate group differences. The largest effects were found for *average seconds between keys*, *variation in seconds between keys*, and *seconds per keystroke*. For these latency-based features, the effect size range ($\delta = 0.33$–0.38) corresponds to approximately a 67% to 69% probability—based on the standard Cliff's Delta derivation—that a randomly selected student from the successful learning group would exhibit a higher feature value than one from the unsuccessful group. Again, as shown in Table 3, students with higher knowledge gains consistently showed higher median values for features related to latency, variability, and editing (e.g., *average seconds between keys*, *keystroke edit distance*), suggesting that slower, more variable, and more corrective early typing behaviors are associated with successful learning. Corresponding findings were obtained when examining continuous associations. Spearman's rank correlations were significant and positive for all features, with coefficients (ρ) ranging from 0.19 to 0.34 (Table 4). This indicates that individual keystroke features explained between 3.6% and 11.6% (ρ^2) of the variance in knowledge gain ranks, with latency-related features again showing the strongest associations. This general upward trend was also visible in the quantile analysis (Table 5), which showed the median values for features such as *average seconds between keys* increasing from the lowest quartile (Q1) to the highest quartile (Q4). These statistical analyses indicate that significant relationships exist between early keystroke features and knowledge gain, motivating the subsequent investigation into their combined predictive power.

3.2 To what extent can we predict Knowledge Gain from Early Keystroke Patterns?

Following the statistical analysis, we evaluated the combined predictive power of the early keystroke features using machine learning models. For both the regression and classification tasks, a suite of different models was tested (see Tables 6 and 7). Although the primary goal of this study is exploratory, the top-performing model is conventionally selected during model selection. We therefore focus our reporting on the performance of the best performing model for each task in terms of the each evaluation metrics used. In the regression task (Table 6), the Random Forest Regressor exhibited the strongest performance among the evaluated models. It achieved the lowest root mean squared error (RMSE = 0.36). We normalized the RMSE using the observed range of the knowledge gain variable (−0.41 to 0.99). After normalization, the RMSE corresponds to 26% of this range. This means that, on average, the model's predictions are off by about one quarter of the total spread of knowledge gain values in the data. The same model also produced the highest correlation between predicted and observed knowledge gains ($r = 0.42$). For the classification task (Table 7), the Random Forest classifier was the top-performing model. It achieved an AUC-ROC of 0.68, indicating that—based only on keystroke patterns from the first two questions—the model has a 68% chance of correctly distinguishing between a randomly chosen eventual successful learner and a randomly chosen unsuccessful learner. The model also achieved an F1-score of 0.71, indicating a strong balance between precision and recall, and a balanced accuracy of 0.67.

Table 6: Regression results for predicting knowledge gain

Model	RMSE	r
Random Forest Regressor	**0.36**	**0.42**
Extra Trees Regressor	0.37	0.40
Decision Tree Regressor	0.39	0.29
Linear Regression	0.40	0.25
Ridge Regression	0.39	0.25
M5prime	0.38	0.37

K*	0.63	0.64	0.63	0.60	0.60

4. DISCUSSION

4.1 Association Between Early Keystroke Patterns and Knowledge Gain

Our results indicate that students who achieved higher knowledge gains engaged with the first two post-instruction mathematics problems in ways that differed systematically from their lower-gaining peers. Specifically, higher-gain students exhibited slower response construction (longer average seconds between keys, longer seconds per keystroke), greater variability in pacing (higher variation in seconds between keys), and more evidence of answer modification and revision (higher keystroke edit distance, correction density, and correction proportion). The observed effect sizes were small to moderate (Cliff's $\delta = 0.15$–0.38), with the strongest associations found for latency-based features. These patterns were consistent across multiple analytical approaches: group comparisons, correlation analyses, and quartile examinations all converged on the finding that slower, more variable, and more corrective early typing behaviors were associated with greater subsequent knowledge gain.

These findings suggest—though do not definitively establish—that students who achieved higher knowledge gains exhibited different behavioral patterns during their first two practice problems compared to lower-gaining students. One plausible interpretation is that slower, more variable typing with greater revision activity reflects more effortful cognitive processing. In mathematics problem solving, pauses between keystrokes could indicate time spent on mental calculation, deliberation about solution strategies, or verification of intermediate steps. Similarly, greater editing activity and a lower ratio of final answer length to total keystrokes may indicate that students reconsidered their initial responses rather than committing to their first attempt.

Notwithstanding, alternative interpretations must be considered. Slower, more variable keystroke patterns could also arise from factors unrelated to productive cognitive engagement, such as lower typing proficiency, confusion or uncertainty that may not always lead to learning, or individual differences in problem-solving tempo. Our analyses cannot distinguish whether these keystroke patterns reflect productive struggle that facilitates learning or whether both the keystroke patterns and subsequent learning are independently driven by underlying factors such as prior knowledge, metacognitive skills, or motivation. Students who already possess stronger foundational knowledge or better self-regulation may naturally exhibit more deliberate, revisionary behavior while also being better positioned to learn from practice. Without experimental manipulation, the observed associations remain correlational.

Moreover, while the correlations we observed were statistically significant, individual keystroke features explained only modest proportions of the variance in knowledge gain (3.6%–11.6%), suggesting that these behavioral signals capture some, but not all, of the factors that differentiate higher- and lower-gaining students. The moderate effect sizes similarly indicate that group differences, while consistent, are not absolute: there is substantial overlap in the keystroke distributions of successful and unsuccessful learners. This overlap suggests that keystroke patterns alone provide an incomplete picture of the learning process.

4.2 Predictive Value of Early Keystroke Patterns

The machine learning analyses provide additional perspective on the practical utility of early keystroke features for anticipating learning outcomes. In the regression task, the best-performing model (Random Forest) achieved an normalized RMSE corresponding to approximately 26% of the observed range of knowledge gain values and a correlation of $r = 0.42$ between predicted and actual gains. In the classification task, the Random Forest classifier distinguished between above- and below-median learners with an AUC-

ROC of 0.68, balanced accuracy of 0.67, and F1-score of 0.71. These results indicate that early keystroke patterns contain a detectable signal about subsequent knowledge gain, but the predictive accuracy is far from perfect.

To contextualize these findings, it is useful to consider what they mean in practical terms. An AUC-ROC of 0.68 indicates that, given two randomly selected students—one who will ultimately show higher knowledge gain and one who will show lower gain—the model has a 68% chance of correctly identifying which is which based solely on their first two problems' keystroke patterns. While this exceeds chance performance (50%), it also means the model will make incorrect orderings approximately one-third of the time. Similarly, the regression model's prediction error of 26% of the knowledge gain range suggests that individual predictions may deviate substantially from actual outcomes in many cases. The classification model's balanced accuracy of 0.67 further indicates that roughly two-thirds of students are classified correctly, leaving one-third misclassified. These levels of predictive performance are comparable to those reported in related early prediction tasks in educational contexts. Prior work predicting wheel-spinning from early problem attempts [4] and forecasting course outcomes from initial interaction data [6, 10] has similarly shown modest but above-chance accuracy. The present findings extend this pattern to the specific case of predicting knowledge gain during skill practice, confirming that early behavioral signals are informative but not deterministic of learning outcomes.

4.3 Implications for Adaptive Learning Systems

Despite the modest predictive accuracy, our findings may have practical value for adaptive instructional systems, particularly when considered in light of the costs and benefits of different types of errors. Prior work in educational data mining has largely focused on detecting sustained unproductive patterns, such as wheel-spinning, where students fail to progress toward mastery despite extended practice [4, 15]. These detection systems typically operate after students have completed many problems, by which point valuable learning time may have been lost. The present results suggest that behavioral differences between higher- and lower-gaining students may be detectable much earlier—specifically, within the first two problems following instruction, before extended practice has occurred. This temporal advantage creates potential opportunities for earlier adaptation, though several important caveats apply. First, the utility of early prediction depends on the availability of effective interventions. If an adaptive system identifies a student as being likely to make limited knowledge gains based on rapid keystroke patterns with minimal revision, the appropriate response is not obvious. Prompting such students to slow down, explain their reasoning, or verify their work might be beneficial if their direct response construction reflects superficial engagement, but could be counterproductive if it indicates genuine fluency or if the additional cognitive load interferes with their learning process. Conversely, students showing slower, more variable patterns with substantial revision might benefit from encouragement or targeted scaffolding, but only if their behavior reflects struggle rather than successful work that happens to be more deliberate.

Furthermore, the modest predictive accuracy means that system-level decisions based on these features should be designed to accommodate uncertainty. Rather than triggering interventions based on early keystroke patterns alone, adaptive systems might use these signals as one input among many—combined with correctness, prior performance, time on task, and other indicators—to inform more nuanced responses. For example, a system might use early keystroke patterns to adjust the probability threshold for offering optional support rather than relying on rigid decision rules. Alternatively, these patterns could inform the sequencing or selection of subsequent problems, steering students toward items that provide appropriate challenge based on estimated learning trajectories.

4.4 Contribution and Open Questions

From a theoretical perspective, our findings contribute to an emerging body of work suggesting that fine-grained behavioral traces, such as keystrokes, can provide insight into learning as it unfolds [1, 6]. The observed associations between early keystroke features and subsequent knowledge gain are consistent with the idea that behaviors reflecting deliberation, self-monitoring, and revision may be detectable in real time and may relate to learning outcomes. However, several important questions remain unresolved. First, the causal mechanisms underlying the observed associations are not established. It remains unclear whether the keystroke patterns themselves reflect cognitive processes that causally contribute to learning, or whether both keystroke behavior and learning outcomes are independently influenced by factors such as prior knowledge, motivation, or self-regulation. Second, the specific cognitive processes that give rise to different keystroke patterns remain inferential. While slower, more variable typing has been interpreted here as potentially reflecting planning or checking, alternative explanations such as retrieval difficulty or hesitation are also plausible. Finally, the temporal dynamics of keystroke behavior and learning are not well understood. Keystroke patterns may evolve across practice, and patterns later in learning may provide different or stronger signals than those observed at the outset. Longitudinal analyses could help clarify how keystroke behavior changes over time and how these changes relate to knowledge gain trajectories.

4.5 Limitations

Several limitations should be noted. First, the data were drawn from a single online mathematics platform, which may limit generalizability. Second, knowledge gain was operationalized using Bayesian Knowledge Tracing estimates, which are model-based inferences rather than direct measures of learning. While BKT is widely used and validated [11], measurement error may attenuate observed associations. Third, the analysis focused on a specific set of keystroke features. Other features capturing different aspects of response construction may provide additional information. Finally, this study examined association and prediction rather than intervention. Experimental studies are needed to determine whether instructional adaptations informed by early keystroke patterns can causally improve learning outcomes.

4.6 Conclusion

In summary, our findings show that early keystroke patterns during the first two problems of skill practice are as-

sociated with subsequent knowledge gain in mathematics, with higher-gaining students exhibiting slower, more variable, and more revision-oriented answer construction. Machine learning models trained on these early features achieved modest but above-chance accuracy in predicting learning outcomes. While these results are consistent with theoretical accounts emphasizing the distinction between performance and learning, they also highlight important limitations and uncertainties. Nevertheless, the findings suggest that fine-grained behavioral data from the earliest moments of independent practice may offer valuable information for understanding and supporting learning trajectories, motivating future work on causal mechanisms, intervention design, and generalizability across domains and contexts.

ABSTRACT

students because it requires students' conceptual change between classical and quantum explanatory frameworks for randomness. Conceptual change in such contexts may not only involve replacing prior knowledge, but also risks overgeneralization, where newly learned concepts are extended beyond their intended scope. In this study, we investigate how students reorganize their reasoning about randomness across classical and quantum contexts following instruction. We analyzed 14,296 open-ended responses collected from pre-test and post-test assessments administered to 1,787 middle school students as part of a quantum-infused science curriculum. Student explanations were classified into classical, quantum, or non-informative reasoning using a large language model fine-tuned on a human-coded subset. A binomial mixed-effects model revealed asymmetric overgeneralization dynamics across problem contexts. Following instruction, overgeneralization decreased in quantum problem contexts, indicating improved alignment between quantum explanations and quantum phenomena. In contrast, overgeneralization increased in classical contexts, reflecting the extension of newly learned quantum reasoning into situations where classical explanations were sufficient. These findings highlight the bidirectional nature of conceptual overgeneralization and underscore the importance of instructional designs that support context-sensitive integration of new scientific concepts.

Keywords

Conceptual change, overgeneralization, quantum randomness, LLM-based classification.

1. INTRODUCTION

Research on conceptual change has emphasized that students' learning of new concepts is not a process of replacement, but one of gradual reorganization of existing knowledge structure [6,10]. Within this framework, overgeneralization can be understood as a pattern that emerges during conceptual change, reflecting students' attempts to coordinate prior knowledge and newly learned information.

Prior work primarily framed overgeneralization as a phenomenon driven by prior knowledge constraining the interpretation of new information [19,20]. From this perspective, students rely on well-established prior knowledge to make sense of a new domain, sometimes leading to explanations that do not fully align with the new domain. However, this overgeneralization also occurs in the reversed direction. As students acquire new information, this newly learned information may itself be overextended, shaping or changing reasoning even in contexts where prior knowledge would otherwise be sufficient [22]. Overgeneralization, therefore, can reflect not only resistance to abandoning old frameworks but also the excessive generalization of newly acquired information beyond its intended scope.

This bidirectional view of overgeneralization is particularly relevant in domains where instruction introduces fundamentally different explanatory principles, such as quantum randomness. When learning quantum randomness, students need to reconcile probabilistic reasoning grounded in classical systems with non-classical sources of indeterminacy [4,17]. In this process, students may incorrectly apply classical randomness to a quantum context, but they may also extend quantum randomness back into classical situations, thereby reshaping their prior conceptual frameworks.

Despite its theoretical importance, overgeneralization during conceptual change has often been examined indirectly, primarily through accuracy-based measures. Such approaches can obscure whether students' responses reflect stable understanding, transitional reasoning, or systematic overextension across contexts. To address this gap, our study examines patterns of overgeneralizations across classical and quantum contexts before and after the instruction, focusing on how students' explanations shift across conceptual boundaries.

2. RELATED WORKS

2.1 Quantum Curriculum for Middle School

Recent years have seen growing interest in introducing quantum information science and engineering (QISE) concepts into K-12 education [15], driven largely by efforts to expand the future quantum workforce. National reports, including those from the National Quantum Coordination Office, have emphasized the importance of developing age-appropriate quantum learning pathways that integrate with existing science and computing curricula, rather than treating quantum topics as isolated and advanced content. In response to this need, initiatives such as The National Q-12 Education Partnership have emerged. However, their curricular recommendations primarily target the high school level. Correspondingly, existing empirical research on K-12 quantum education has

overwhelmingly focused on high school students (e.g., [5,16]), with comparatively little attention to middle school students.

Despite its imbalance, a growing body of evidence suggests that middle school students are cognitively capable of engaging with core ideas in modern physics, including foundational quantum concepts [1,7,13]. For example, prior work has demonstrated a saturation effect in post-test performance, indicating that no intrinsic cognitive barriers prevent middle school students from understanding key Einsteinian ideas such as curved spacetime or photon momentum [7]. Moreover, longitudinal findings show that students were able to recall central concepts (e.g., "space is curved," "light comes as photons") one to three years after instruction, suggesting durable conceptual understanding rather than short-term memorization [13]. Together, these findings challenge assumptions that quantum concepts are inherently inaccessible at the middle school level.

Building on this evidence, a small but growing literature on middle school quantum education has focused on two primary areas: (1) the development of effective pedagogical interventions and (2) teacher education and professional development for quantum curriculum implementation. A portion of this work has examined teacher preparation. Survey and interview studies with middle and high school teachers consistently show that the successful introduction of quantum topics depends heavily on teacher self-efficacy, conceptual confidence, and access to sustained support [2,11]. This highlights the role of professional development (PD) in co-designing their quantum curriculum [1]. Teachers often express strong motivation to engage with quantum science due to its perceived relevance and future-oriented appeal, while simultaneously reporting concerns about curricular alignment and their own content knowledge.

In parallel, research on instructional design has explored how middle school students can meaningfully engage with quantum concepts by deemphasizing mathematical formalism and instead foregrounding conceptual, experiential, and interactive learning modalities [7,13,14,21]. For instance, one study employed a gamified puzzle environment to teach quantum logic gates, finding that students required substantial scaffolding and frequently bypassed textual explanations, which motivated designs that embed learning directly into gameplay mechanics. Other work has leveraged interdisciplinary approaches, such as using music education to introduce quantum atomic models to 12-13-year-olds [21]. This interdisciplinary approach resulted in high post-test performance. Finally, the Einstein-First project exemplifies a complementary approach that replaces traditional Newtonian instruction with Einsteinian concepts through concrete physical models. Interventions in the project included using Nerf guns to represent photons (demonstrating momentum and uncertainty) and lycra sheets with marbles to visualize curved spacetime [7,13]. These studies support the feasibility of introducing modern physics concepts at the middle school level.

2.2 Teaching quantum randomness

However, demonstrating the feasibility of teaching quantum concepts at the middle school level does not imply that all quantum ideas are equally accessible. Among basic quantum concepts [9], the probabilistic nature of quantum phenomena is central for understanding the behavior of quantum entities. Prior research suggests that students often approach quantum physics with intuitions grounded in everyday experience, treating quantum entities as classical objects that follow definite trajectories through space and time [12]. This reliance on everyday experiences and classic objects creates substantial conceptual barriers when students encounter quantum phenomena that require fundamentally different explanatory assumptions.

Specifically, researchers investigated how students interpret probability and randomness in quantum contexts and categorized students' interpretations into three types, including a classic type, a mixed type, and a quantum type [17]. The classical type refers to students' interpretation where randomness is treated as epistemic uncertainty caused by incomplete information or imperfect measurement. The mixed type refers to an interpretation where students assume hidden information exists but is practically inaccessible. Lastly, in the quantum type, students treat individual outcomes as inherently unpredictable while recognizing that collective behavior can be predicted statistically. This framework highlights that the critical distinction between classical and quantum randomness lies not in whether individual outcomes are difficult to predict, but in the source of that unpredictability. In the classical view, unpredictability arises from incomplete information. Given sufficient knowledge of all relevant variables, outcomes are determinable, in principle. In the quantum view, unpredictability is intrinsic to the system. Even with complete knowledge of the system's state, individual outcomes remain fundamentally indeterminate.

2.3 Conceptual Change and Overgeneralization

Conceptual change research characterizes learning as a process of knowledge integration that unfolds gradually, during which students actively reorganize existing ideas rather than simply replacing them [6,10]. Within this framework, overgeneralization has been widely documented as a mechanism through which students extend familiar principles beyond their valid scope. Much of this work has focused on cases in which entrenched prior knowledge constrains the interpretation of new information, such as the application of whole-number reasoning to rational numbers [19], linearity assumptions in non-linear domains [20], or deterministic intuitions in probabilistic and stochastic systems [4]. In these accounts, overgeneralization is often interpreted as evidence of robust prior knowledge that resists accommodation. However, other strands of overgeneralization can also arise when newly learned concepts are overextended or inappropriately activated in contexts where previously established forms of reasoning would have been sufficient [4,8,22]. From this perspective, overgeneralization can reflect not only resistance to conceptual change, but also productive sense-making during the reorganization of knowledge structures, which occur in both directions. While prior knowledge constrains new learning, newly acquired concepts are overextended into familiar domains.

Thus, because conceptual change involves ongoing reorganization of knowledge, overgeneralization is often difficult to capture with summary performance measures alone. Accordingly, many conceptual change studies have examined students' strategies and explanations in depth. For example, prior research has analyzed students' written explanations, interview responses, and problem-solving justifications to characterize the reasoning strategies students apply across tasks [4,19,20]. However, such fine-grained analyses are typically time-intensive and therefore difficult to scale, particularly when studying large populations or multiple task contexts. As a result, relatively little work has systematically examined patterns of reasoning across contexts using large collections of student explanations.

Addressing this gap requires analytic approaches that can simultaneously preserve sensitivity to students' explanatory reasoning and operate at scale across multiple task contexts. Recent work in

educational data mining has demonstrated the feasibility of using large language models to automatically assess rich, open-ended student data [3,18]. Therefore, in the present study, we adopt a Large Language Model-assisted analytic approach to examine large collections of student explanations across classical and quantum randomness contexts.

3. RESEARCH QUESTIONS

Building on prior works, the present study examines how students' reasoning about randomness reorganizes after their first formal exposure to quantum randomness in a middle school science setting. This investigation is situated within a larger evaluation of a quantum-infused curriculum that introduces quantum randomness through instruction on radioactive decay. This topic already involves classical probability within existing science standards. By comparing students' written explanations across pre- and post-test items designed to elicit classical and quantum interpretations of randomness, we analyze whether overgeneralization dynamics shift asymmetrically across contexts as students integrate new conceptual knowledge.

Accordingly, we address the following research question:

RQ) How do overgeneralization patterns differ across classical and quantum contexts before and after curriculum, and what asymmetries emerge in these dynamics?

4. DATASETS

4.1 Quantum-Infused Science Curriculum

We co-designed the 7-day-long quantum education curriculum for middle school students with middle school science teachers. We aim to align the curriculum with classroom constraints and be accessible to typical middle school students. The first half of the curriculum introduces randomness in an Earth and Space Science context, starting with instruction on radioactive decay and radiometric dating. Students begin with an archaeology-themed challenge (e.g., estimating the age of remains) and then learn how Carbon-14 decays into Nitrogen-14 over time, using half-life as a statistical model for decay rates rather than a deterministic prediction of individual events. In the following lessons, students engage with isotopes, decay types, and hands-on modeling activities (e.g., popcorn and coin-flip analogies) to build an intuitive distinction between what can be predicted in aggregate (i.e., the decay rate) versus what cannot be predicted at the level of a single atom (i.e., which nucleus decays next). At this stage, students are expected to understand this unpredictability as classical randomness, arising from practical complexity (i.e., too many variables to track). They are not yet expected to understand any fundamental indeterminacy in the system itself.

The second half of the curriculum then extends beyond existing standards-based science content by explicitly introducing the concept of quantum randomness. They now explore randomness in the context of quantum indeterminacy and learn how quantum random number generators produce unpredictable outcomes that cannot be explained by hidden variables or measurement limitations. Students apply this idea in an activity that involves generating binary numbers, converting them to hexadecimal codes using real quantum-generated data from an online quantum lab, creating random colors, and using them in their artwork. This final lesson positions quantum randomness as an extension of students' prior reasoning about probability, while discussing boundary conditions for when classical explanations are sufficient versus when quantum explanations are needed.

4.2 Participants and Dataset

Participants were middle school students enrolled in regular science classes at seven public middle schools in the Midwestern United States. Across the schools, a total of 1787 students participated in both the pre-test and post-test. Approximately 25.4 % of students were in 6th grade, 37.0% were in 7th grade, and 37.6% were in 8th grade. Female students comprised 49.3% of the sample, while male students comprised 50.7%. Students were recruited through classroom participation during regular instructional activities, and no prior instruction on quantum randomness was assumed.

Each student responded to four assessment items (i.e., two items asking the classical randomness concept and two items asking the quantum randomness concept) in the pre-test and the same four items in the post-test, resulting in a total of 8 responses per student. The example of the question is shown in Figure 1 below. Across all participants, this yielded 14,296 total responses in the full dataset used for large-scale analysis. This study was reviewed and approved by the Institutional Review Board at Purdue University (IRB-2022-1016). We randomly selected a subset of responses from 100 students for detailed human coding and model calibration. This subset comprised 800 responses (4 items × pre/post × 100 students). We used this subset to establish coding reliability, train, and evaluate automated classification models. The remaining responses formed the dataset for population-level analyses of conceptual reasoning and overgeneralization dynamics.

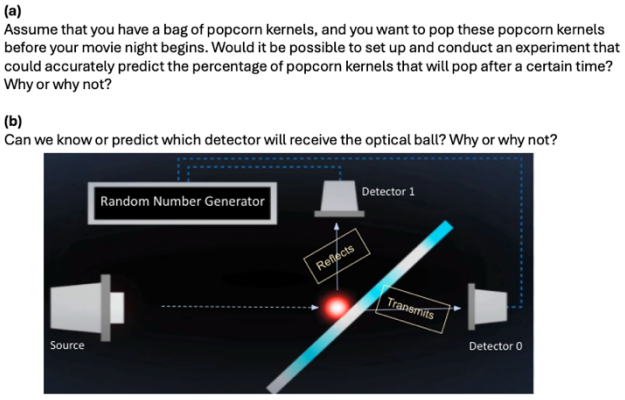

Figure 1. Example test items used in both pre-test and post-test. (a) is a classical randomness item asking whether the outcome of popcorn popping can be accurately predicted in advance and why. (b) is a quantum randomness item depicting a single-photon beam splitter setup, asking whether one can know or predict which detector will register the optical signal and why.

5. ANALYSIS

5.1 Coding Scheme

We developed the coding scheme through an iterative, theory-informed process. We first derived an initial set of codes from the theoretical distinction between classical randomness and quantum randomness, informed by prior research on middle school students' understanding of quantum randomness [17]. We then applied these preliminary codes to a subset of student responses to identify ambiguities, overlaps, and borderline cases. Through iterative discussion, we refined the code definitions to ensure conceptual clarity, mutual exclusivity, and applicability across both classical and quantum contexts. The refinement was done with the understanding that coding of student responses did not aim to assess correctness per se, but rather to characterize the dominant

conceptual basis underlying each student's response. Crucially, the coding distinguished responses based on the attributed source of unpredictability, rather than on the acknowledgment of unpredictability itself. For example, in the popcorn item in Figure 1, attributing unpredictability to practical complexity (e.g., varying moisture or heat) was coded as classical, whereas treating individual outcomes as fundamentally indeterminate was coded as quantum. The latter constitutes overgeneralization because popcorn popping is governed by deterministic physical processes that are, in principle, predictable given sufficient information. This process yielded a three-category coding scheme, summarized in Table 1.

Using this coding scheme, two trained researchers independently coded a subset of students' open-ended responses. This human-coded dataset consisted of responses from 100 students, each answering four items in both pre-test and post-test, yielding a total of 800 responses. The overall inter-rater reliability (Cohen's κ) was $\kappa = 0.8227$, indicating strong agreement beyond chance. Specifically, 0.8143 for classical, 0.8450 for quantum, and 0.8227 for non-informative.

5.2 LLM-Based Response Classification

To enable large-scale analysis of student reasoning, we used a large language model (LLM) to classify the remaining student responses that were not manually coded. We fine-tuned a pretrained instruction-following LLM (*Meta-LLaMA-3.1-8B-Instruct*) using parameter-efficient fine-tuning with low-rank adaptation (LoRA). We split the human-coded student responses described above into training and validation sets. The model was trained on this training set.

We evaluated the trained model's performance using the validation set exclusively held out for model evaluation. To account for class imbalance across conceptual categories, we report both macro-averaged and weighted F1 scores, along with category-level precision and recall. After validation, we applied the trained model to fully code the remaining full dataset of 13,078 responses after excluding empty responses.

5.3 Operationalizing Overgeneralization

We operationalized overgeneralization as cross-contextual misalignment between the problem context and the category of conceptual reasoning expressed in student responses. For each response, we compared the coded conceptual category with the problem context. We coded overgeneralization as present when a student applied quantum reasoning to a classical problem context or classical reasoning to a quantum problem context.

We excluded responses coded as non-informative from overgeneralization analyses because they did not provide sufficient evidence of a coherent conceptual framework. This binary overgeneralization variable served as the primary outcome in subsequent statistical analyses examining change over test time (i.e., pre-test and post-test) and problem contexts.

5.4 Statistical Analysis

To examine changes in overgeneralization across test time (i.e., pre-test and post-test) and problem contexts, we employed a binomial mixed effects modeling approach. The dependent variable was the binary overgeneralization indicator. Fixed effects included the test time (pre vs. post), problem context (classical vs. quantum), and their interaction. Random intercepts were included for students and test items to account for repeated measurements and problem-level variability.

Table 1. Three-category coding scheme used to classify students' reasoning of randomness in classical and quantum test items.

Code	Definition	Example
Classical	Randomness is treated as epistemic rather than fundamental. Outcomes are assumed to be determined by underlying physical causes and, in principle, predictable given complete information. Uncertainty is attributed to limited knowledge, measurement constraints, or statistical aggregation.	"Yes, you would have to do a lot of re-testing and starting the whole experience over again. You could look in your microwave and see how many pop in a minute."
Quantum	Randomness is treated as fundamental to the physical system. Even with complete knowledge of the system, the outcome of an individual measurement is considered inherently unpredictable, reflecting intrinsic indeterminacy rather than lack of information.	"We cannot predict which detector will receive the optical ball. It is random, so we don't know if detector 1 or detector 0 will get it."
Non-Informative	Responses that are off-topic, vague, or non-conceptual, including expression of uncertainty or yes/no answers without explanatory reasoning.	"I don't know", "idk", "No, because I don't want to wait to watch the movie."

6. RESULTS

6.1 Validating LLM-based Classification Against Human Annotation

Before analyzing the overgeneralization pattern in the full dataset, we assessed the LLM-based classification performance against the human-coded validation set. The model achieved an accuracy of 0.8841, a macro F1 score of 0.8316, and a weighted F1 score of 0.8803. The code category-specific level's F1, precision, and recall scores were shown in Table 2. Precision and recall scores indicated that the model was most reliable in distinguishing students' classical reasoning and quantum reasoning.

Table 2. Classification performance of the LLM-based model by conceptual category on the human-coded validation set.

Code	Precision	Recall	F1
Classical	0.885	0.955	0.919
Quantum	0.750	0.600	0.667
Non-Informative	0.962	0.862	0.909

6.2 Distributed Patterns of Conceptual Reasoning

Prior to instruction, students' pre-test responses in the classical problem context were predominantly classified as classical reasoning (75.32%), with only a smaller proportion reflecting quantum reasoning (4.83%). In contrast, responses to the quantum problem context showed a substantial reliance on classical reasoning (68.13%), indicating that students largely interpreted quantum phenomena using classical conceptual reasoning before the instruction. Table 3 summarizes the distribution of conceptual reasoning across problem context and test times.

Table 3. Pre-test and post-test distributions of classical, quantum, and non-informative reasoning by problem context.

Problem context	Test time	Classical	Quantum	Non-Informative
Classical	Pre	75.32%	4.83%	19.85%
	Post	64.78%	15.45%	19.77%
Quantum	Pre	68.13%	14.44%	17.43%
	Post	56.49%	29.23%	14.28%

Following the instruction on quantum randomness, the overall distribution of conceptual reasoning shifted in the post-test (Figure 2). In the quantum problem context, the proportion of quantum reasoning increased to 29.23%, accompanied by a decrease in classical reasoning to 56.49%, suggesting increased uptake of non-classical reasoning.

Notably, a parallel shift also occurred in the classical problem context. Despite the classical nature of the problems, the proportion of responses classified as quantum reasoning increased from 4.83% in the pre-test to 15.45% in the post-test.

6.3 Overgeneralization Dynamics Across Problem Context and Test Time

Our binomial mixed-effects model revealed meaningful effects of both test time and problem context on students' overgeneralization patterns. First, the main effect of time showed a positive posterior mean (β = 1.31, 95% credible interval = [1.24, 1.37]), indicating that, on average, overgeneralization became more likely following instruction. The 95% credible interval for this effect did not include zero, providing posterior evidence for an overall increase in overgeneralization across problem contexts. The main effect of context also showed a positive posterior mean (β = 4.22, 95% credible interval = [4.15, 4.29]), suggesting substantially higher baseline overgeneralization rates in the quantum problem context compared to the classical problem context.

Critically, the interaction between test time and problem context showed a negative posterior mean (β = -2.22, 95% credible interval = [-2.31, -2.13]). This pattern indicates that instructional effects on overgeneralization diverged across problem contexts. Specifically, while overgeneralization decreased in the quantum problem context following instruction, it increased in the classical problem context, reflecting a problem-context dependent reorganization of students' conceptual reasoning. These posterior estimates from the mixed-effects model are reported in Table 4.

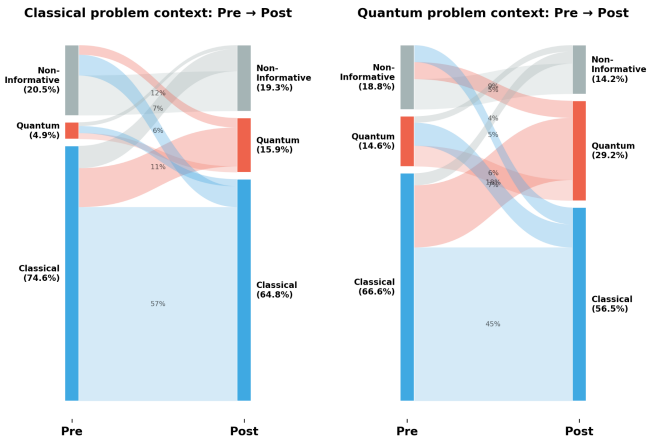

Figure 2. Sankey plot showing transitions in students' response from pre-test to post-test in classical (left) and quantum (right) problem contexts. Each band represents the flow of responses from a pre-test to a post-test.

Table 4. Posterior estimates from the binomial mixed-effects model predicting overgeneralization.

	Posterior mean (β)	Posterior standard deviation	95% Credible interval (CrI)
Intercept	-2.680	0.028	[-2.74, -2.63]
Test time	1.305	0.034	[1.24, 1.38]
Problem context	4.217	0.035	[4.15, 4.29]
Test time × Problem context	-2.219	0.045	[-2.31, -2.13]

Figure 3 summarizes model-predicted probabilities of overgeneralization across test time and problem context, derived from the binomial mixed-effects model and transformed from the logit scale. In the classical problem context, predicted overgeneralization increased from 6.42% in pre-test to 20.19% in post-test. In contrast, in the quantum problem context, predicted overgeneralization decreased from 82.31% in the pre-test to 65.11% in the post-test. These estimates reveal a qualitative asymmetry. This pattern indicates an asymmetric shift in explanatory tendencies across problem contexts: post-instruction responses showed reduced context-reasoning mismatch in the quantum problems but increased mismatch in classical problems. These changes mirror the interaction effect observed in the mixed-effects model, suggesting that shifts in overgeneralization differed systematically by problem contexts.

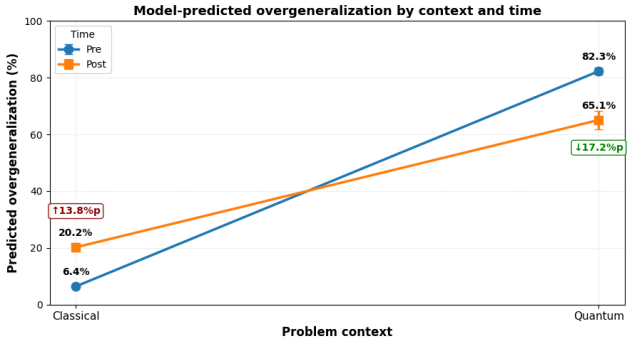

Figure 3. Model-predicted overgeneralization rates by problem context (classical vs. quantum) and time (pre- vs. post-test). Annotations indicate the change in percentage points from pre- to post-test within each context.

7. DISCUSSION

This study examined how middle school students' reasoning about randomness reorganizes across classical and quantum problem contexts following the curriculum implementation, with a particular focus on overgeneralization. From an educational data mining perspective, our work demonstrates how large-scale analyses of open-ended student explanations can uncover systematic patterns of conceptual change and overgeneralization that are challenging to observe through correctness-based metrics alone. By integrating LLM-based classification with mixed-effects modeling, we illustrate how EDM methods can be used to model fine-grained shifts in students' explanatory reasoning across contexts and time in quantum education.

Firstly, our results provide empirical support for a bidirectional account of overgeneralization during conceptual change in quantum education, revealed through large-scale analysis of open-ended responses. Overgeneralization of classical reasoning in quantum problem contexts decreased after students completed the curriculum, while overgeneralization of quantum reasoning in classical contexts increased. Prior work has largely framed overgeneralization as the transfer of entrenched prior knowledge into newly learned domains (e.g., [18, 19]). Consistent with this view, students initially relied heavily on classical reasoning when interpreting quantum randomness. Following the curriculum, such an initial reliance decreased in quantum contexts, indicating improved understanding of quantum randomness. However, newly acquired quantum reasoning was increasingly applied even to classical contexts where classical explanations were sufficient. From an EDM standpoint, this asymmetric pattern represents the value of modeling context-dependent reasoning trajectories rather than treating learning gains as uniform improvements. Large-scale classification of explanations enables detection of such directional shifts, which would likely be obscured in accuracy-only analyses.

Secondly, the observed bidirectional overgeneralization has implications for data-informed curriculum design in middle school quantum education. The increase in quantum reasoning in classical contexts suggests that students actively integrate newly learned frameworks into existing knowledge structures, even when this integration exceeds normative boundaries. Similar challenges in distinguishing explanatory frameworks have been reported in prior studies of quantum reasoning and conceptual change (e.g., [3, 16]). In our curriculum, classical and quantum randomness were intentionally taught together to align with state standards and the pre-set annual teaching plan, with instruction beginning from classical probability and concluding with quantum randomness. While such a curricular design successfully and practically promoted quantum reasoning, it may also have increased the likelihood of quantum overgeneralization in classical contexts. These findings suggest that EDM approaches can play a critical role in evaluating instructional trade-offs and thus help curriculum designers identify when instructional success in one domain introduces unintended conceptual spillover into another. Explicit scaffolds that clarify boundary conditions may therefore be necessary to stabilize students' reasoning across classical and quantum science contexts.

Last but not least, this study demonstrates the methodological potential of LLM-assisted educational data mining for studying conceptual change using open-ended student responses. Prior work has shown that LLMs can reliably assess rich student explanations at scale (e.g., [2, 17]). Building on this work, we show how validated LLM-based classifications can be integrated with statistical modeling to examine population-level patterns of reasoning reorganization. This approach is particularly valuable for underrepresented student populations, such as middle school students in quantum education, where large datasets of open-ended responses have rarely been explored and are difficult to analyze manually.

Nevertheless, limitations remain. First, the three-category coding scheme, while aligned with the theoretical distinction central to our research question, may not capture finer-grained variations such as mixed or transitional reasoning. To capture such details of students' conceptual trajectories, future studies could explore how to sophisticate coding schemes. Second, automated classification can introduce uncertainty into coding results, particularly for the quantum category, where the model achieved a recall of 0.60, suggesting that quantum reasoning may be underestimated in our analyses. This limitation likely makes our central finding conservative, as the true extent of quantum reasoning in classical contexts may exceed what is reported. Future work could address this through different strategies, such as oversampling the quantum minority class during training and applying class-weighted loss functions to improve classification performance under class imbalance. Lastly, our analysis focused on short-term instructional effects; longitudinal EDM analyses are needed to examine how overgeneralization patterns evolve over longer timescales and across instructional contexts.

8. CONCLUSIONS

Our study contributes to research on conceptual change by empirically demonstrating that overgeneralization during learning is not a unidirectional phenomenon but can occur as a bidirectional phenomenon. In the context of learning quantum randomness, students showed both reduced inappropriate reliance on classical reasoning in quantum problem contexts and increased application of quantum reasoning in classical problem contexts following instruction. These asymmetric shifts highlight that conceptual change involves not only replacing or constraining prior knowledge but also negotiating the boundaries of newly acquired concepts. From an educational perspective, our findings suggest that successful instruction should be evaluated not only by gains within the target domain but also by how newly learned concepts interact with students' existing knowledge across contexts. Specifically, for quantum education at the middle school level, this implies a need for instructional designs that explicitly address the scope and limits of quantum explanations, helping students differentiate when quantum reasoning is appropriate and when classical explanations remain sufficient.

ABSTRACT

In this demonstration, we present the Quick Red Fox (QRF) system, a system design to assist researchers in conducting Data-Driven Classroom Interviews (DDCIs). DDCIs enables researchers to collect rich qualitative interview data at key moments of the students' interaction with a digital learning environment. Using the QRF system, researchers can use EDM methods to analyze logs of student interaction data, identify interview triggers and provide classroom interviewers with real-time interview requests on a handheld Android app. We describe the main components of the QRF system (the QRF android app, the QRF server and the QRF dashboard) and demonstrate the usage of QRF in the context of WHIMC, a Minecraft-based learning system in which students learn about astronomy.

Keywords

Data-driven interviews, digital learning environments, mixed-method research.

1. INTRODUCTION

The analysis of student interaction log data using EDM approaches has been successfully used to achieve a range of educational goals ranging from the use of Discovery with Models to improve our understanding of student learning processes (as described in [1]), to generate data-driven student support (such as data-driven feedback, recommendations or interventions; [2], [3]), to design student and teacher facing learning dashboards ([4], [5]), and to inform the design of learning tasks and learning environments ([6], [7], [8]). In this demonstration, we present the Quick Red Fox (QRF) system, a system that leverages EDM methodologies to support the collection of rich in-the-moment qualitative data. Using this system, researchers can leverage data-driven analyses of students' interaction log data to collect Data-Driven Classroom Interviews (DDCI) at key moments in the students' usage of digital learning environments.

2. DATA-DRIVEN CLASSROOM INTERVIEWS (DDCI)

The purpose of QRF is to provide researchers with immediate, and contextualized students reactions to learning systems. Unlike other methods that attempt to capture *in situ* data, such as Think Aloud methods [9], QRF allows us to target specific learning events that are detectable in a learning software so that researchers can observe and interview students while that event is still fresh in their minds. In that way, we can ensure that interviewers are able to provide students with questions about those experiences that help us to address underlying research questions, and we can do so without asking the student to carry the metacognitive load of figuring out what would be relevant to the research question, which is sometimes a criticism of methods like Think Alouds [10].

DDCIs are often very short (3-7 minutes). Questions may vary depending upon the underlying research question, and interviewers are encouraged to develop a range of question strategies before entering the field, as they are likely to have many DDCIs with each student over the course of a fieldwork experience. For example, if students are using the system for an hour a day, it might not be unusual for a single student to be interviewed more than once, and if the fieldwork efforts extend over a week, the same interviewer may talk to one student a dozen times.

Interviewers are trained to take a friendly but non-authoritative approach where they express interest about the students' experience [11]. This allows them to pivot to specific questions about the students' immediate experience without becoming bogged down with questions about how the learning system works or with requests from the student to have the interviewer explain the learning material. Instead, if the student is struggling, the interviewer might ask what strategies they have already tried, which strategies they might still need to try, and more generally how the student usually goes about dealing with learning obstacles.

This approach allows the interviewers to establish student trust, so that they are willing to make suggestions about what might improve their learning or engagement. As such, the approach lends itself well to investigating research questions about both the difficulties that students might be having at any given moment and about any assets students bring to the learning context [12].

3. THE QUICK RED FOX (QRF) SYSTEM

The QRF system provides multiple inter-related components (the QRF android app, the QRF server and the QRF dashboard) that can be used together to facilitate the implementation of DDCIs using an existing digital learning system (see Figure 1). QRF is made available as an open-source system and its user manual provides instructions about how to access the QRF source code and the steps required to setup a QRF server (see "Appendix 2: Installing the QRF server" of the user manual [11] for detailed instructions).

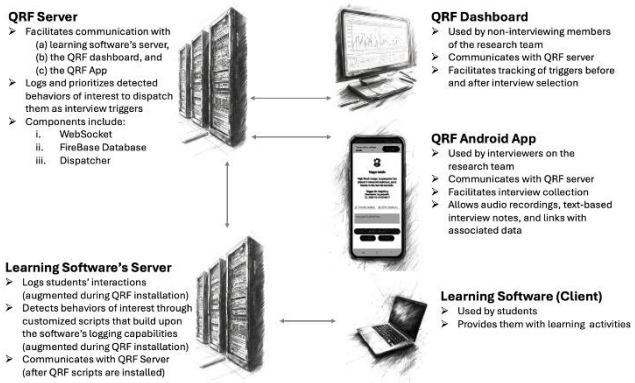

Figure 1. Overview of the QRF system, its different components and the interactions between each component.

3.1 The QRF Android App

The QRF Android App is the tool used by interviewers to conduct DDCIs. Interviewers are first asked to login to the app with their username. Once logged in, the app waits for the QRF server to send it an interview trigger (see left of Figure 2). The right side of Figure 2 shows the app's interface after it receives an interview trigger. It provides the interviewer with information about the trigger that was just received, including the trigger's description, which student triggered the interview prompt and the time at which the trigger was detected.

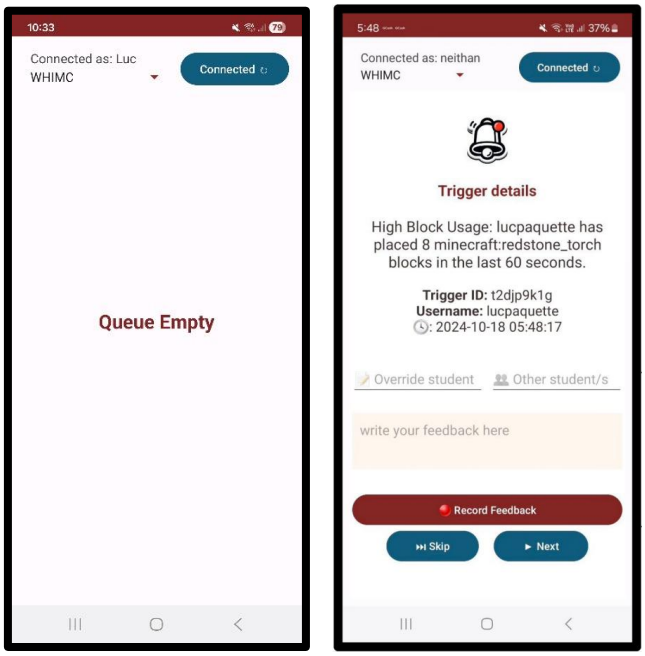

Figure 2. The QRF app. On the left, the interviewer connected to the QRF server and is waiting for an interview trigger. On the right, the QRF server sent an interview trigger to the interviewer.

Once an interview prompt is provided to the interviewer, they can review the prompt to decide whether they would prefer to skip this interview, for example when the student's attention is already occupied and they should not be disturbed. If the interviewer decides to proceed with the interview, it can be recorded directly through the app by pushing the "Record Feedback" button (we recommend using an external, directional microphone that can help with reducing background noise). Audio recordings are stored locally on the phone. In addition, the QRF app can be configured to automatically send the recordings to a data server. Interviewers can also add text notes to provide additional contextual information about the interview. They can "override" the interviewed student if they have observed a salient event from another student that they wish to interview as soon as possible. Through our past interviews, we have also observed that neighboring students sometimes join ongoing interviews. In such a case, the app allows the interviewer to make explicit note of which "Other student/s" joined the interview. Finally, once an interview is completed, the interviewer pushes the "Next" button. The app then sends information about the interview to the QRF server and goes back to waiting for the next available interview prompt.

3.2 The QRF server

The central component of the QRF server is the dispatcher program which is responsible for receiving interview triggers from the learning system, keeping track of active triggers for each student and dispatching triggers to classroom interviewers.

Communication between the learning environment, the dispatcher program and the QRF app uses the websocket communication protocol. When the learning environment detects a situation that was identified as an interview trigger, it sends information about this trigger (its description, what students triggered it, and its priority) to the dispatcher. The dispatcher receives the triggers and organizes them in a queue, based on their priority (a numerical value provided by the learning environment along with the trigger). Triggers are maintained in the queue for a predetermined amount of time (can be adjusted by the researchers) before they timeout and are removed from the queue. This mechanism prevents interviewers from being asked to interview students for a trigger that happened too long ago and is no longer relevant.

When the QRF app notifies the dispatcher program that an interviewer is available, the dispatcher selects the trigger with the highest priority and sends it to the QRF app. In addition to the numerical priority of the triggers, the dispatcher implements mechanisms to avoid frequent repeated interviews of the same student. The dispatcher can be configured to enforce a minimum waiting period between the end of an interview and the next interview request for the same student. This mechanism is designed to minimize situations where a student might experience interview fatigue and maximize the chances that all students are interviewed during data collection.

Throughout this process, the dispatcher program logs all the received triggers to a Firebase database to keep records of which trigger was received, for which student and at what times. It also logs information about which interviewer (if any) received the trigger on their QRF app, and whether the interviewer decided to skip the interview request. If an interview is conducted, the dispatcher also logs metadata about the interview (e.g., when did the interview start, how long did it last, did the interviewer add any text note to the interview, etc.)

3.3 The QRF dashboard

The QRF dashboard is a web browser-based interface that allows the research team to monitor interview triggers and interviews during data collection. The dashboard can be configured to interface with both the Firebase database (storing information about the detected interview triggers and the resulting interviews) and the data server used to store audio recordings (if a data server is used).

The dashboard displays a table with information about each trigger that has been sent to the dispatcher program. It is automatically updated at regular intervals to display the most recent triggers. During data collection, the dashboard is typically used by the research team as a way to verify that the QRF system is functioning as expected (e.g., triggers are being received by the dispatcher and logged in the database), and to monitor which triggers are being received by the dispatcher and which ones are sent to the interviewers. Such real-time monitoring of the received trigger can be useful to identify whether any adjustments of trigger priorities might be warranted during data collection to increase the likelihood that a rare, but important trigger will be forwarded to interviewers. If audio recordings are being uploaded to a data server, the dashboard can also be configured to access the audio recordings, allowing the research team to playback interviews from the dashboard.

4. DDCI IMPLMENTATION IN WHIMC

In this demo, we will show an example of how the QRF system has been integrated with WHIMC (What-if Hypothetical Implementations in Minecraft) [13], a Minecraft-based learning system in which students learn about astronomy while exploring virtual recreation of hypothetical Earths (e.g., what would Earth be like if there were no moon). The WHIMC system includes two main types of learning activities: exploration of what-if worlds and building a space habitat on Mars.

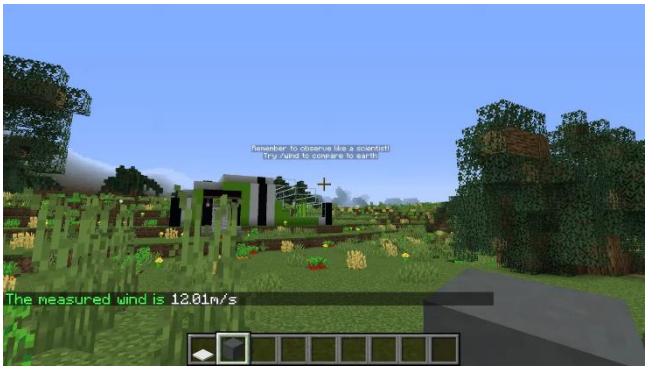

Figure 3. Screen captured from the WHIMC system. The student used one of the available measurement tools to measure the speed of the wind in the current world.

Figure 4. Screen captured from the WHIMC system. The student made a new observation about the color of the sun in this world.

During what-if exploration worlds, students are asked to explore a virtual recreation of a what-if Earth and to investigate how this Earth differs from ours. During their exploration, students can, at any moment, use scientific measurement tools (e.g. Figure 3) to collect data about different aspects of the what-if world (e.g., its gravity, wind speed, temperature, etc.). They can also write down observations (e.g. Figure 4) that are displayed in the world, at the coordinates where the observation was made. Throughout their exploration students may encounter various non-player characters (NPCs) and points of interest (e.g., a greenhouse, a windmill, etc.) that provides them with clues about the differences between the virtual world they are exploring and our Earth, and about which measurement tool might provide them with relevant information about these differences. Students typically explore each exploration world for a short period of time (around 20 minutes).

During the Mars habitat building activity, students interact with the recreation of a part of Mars. They work in small groups (2-3 students) with the goal of building structures that could be used as a habitat on Mars. Students are given instructions about characteristics of a habitat that would make it appropriate for life on Mars (e.g., does the habitat have a source of food and water, does it have a source of electric power, etc.) Students typically work on their Mars habitat for 3-4 hours across 2 days.

As part of this demo, participants will be able to interact with the WHIMC learning environment. They will be shown how their actions in WHIMC (e.g., using a scientific tool near an NPC or using a specific type of block during Mars habitat building) activate predetermined interview triggers requests. They will be able to interact with the QRF app to record short interviews and see how logs and audio recordings of their interviews are being reported on the QRF dashboard. The demo will also show an example of a simple Python script illustrating how triggers are sent to the QRF server from the learning environment.

ABSTRACT

Digital learning platforms enable large-scale randomized controlled trials (RCTs) in real classroom settings, where students are nested within classrooms and outcomes are shaped by both individual characteristics and shared environments. Although randomization at the student level helps balance these factors, differences across classrooms may still persist, motivating the need for covariate adjustment.

In this paper, we study whether and how accounting for classroom structure improves treatment effect estimation. Standard approaches, such as fixed- and random-effects models, adjust for classroom variation and can improve precision, but they rely on parametric assumptions and may fail to capture complex or nonlinear relationships.

We build on the Leave-One-Out Potential outcomes (LOOP) estimator, which uses machine learning to flexibly model outcomes while preserving unbiasedness. However, LOOP struggles with high-cardinality categorical variables, such as classroom identifiers. To address this limitation, we propose *Ordered LOOP*, a method designed to better incorporate such variables.

Through simulations and real data applications, we show that accounting for classroom structure improves precision. Ordered LOOP performs particularly well when outcome heterogeneity is complex or nonlinear, while remaining competitive in simpler settings. Overall, our results highlight the importance of modeling classroom structure and demonstrate that Ordered LOOP provides a flexible, robust, and unbiased approach for analyzing hierarchical educational data.

Causal inference, A/B testing, Online learning platforms, Hierarchical modeling, Covariate adjustment

1. INTRODUCTION

Digital learning platforms allow researchers to conduct large-scale A/B tests and collect rich student-level data in real classroom settings. As their use grows, so does the need for methods that deliver valid and precise causal estimates in real-world environments. A key challenge is the hierarchical structure of educational data: students are nested within classrooms, teachers, and schools, and outcomes reflect both individual characteristics and shared learning environments [2].

Although student-level randomization is intended to balance these factors, real-world experiments often fall short. For example, analyses of ASSISTments experiments [6] show that many classrooms include only a single participating student [11], limiting the effectiveness of randomization and motivating covariate adjustment. Prior work [2] shows that accounting for classroom structure using fixed- or random-effects models can improve precision. However, these approaches rely on parametric assumptions and may fail to capture complex, nonlinear, or interactive relationships, especially when group structures are unknown.

To address these limitations, we study the Leave-One-Out Potential outcomes (LOOP) estimator [4, 14], which uses machine learning to flexibly model outcomes while preserving unbiasedness. Random forests are well suited to this framework because they naturally produce out-of-bag predictions aligned with the leave-one-out structure. However, standard implementations struggle with high-cardinality categorical variables, such as classroom identifiers, due to computational constraints.

We propose *Ordered LOOP*, an extension that enables effective adjustment for such variables. We evaluate the method using simulations based on real-world data and real experimental datasets [12] . Our results show that accounting for classroom structure improves precision, and that Ordered LOOP performs particularly well when classroom effects are complex or nonlinear, while remaining competitive in sim-

pler settings. In these complex settings, it outperforms common alternatives, including OLS, OLS with classroom fixed effects, and hierarchical linear models with random effects.

The remainder of the paper is organized as follows. The next section reviews the potential outcomes framework, LOOP, and Ordered LOOP. Section 3 describes the simulation design, Section 4 presents the results, and Section 5 concludes.

2. CAUSAL ESTIMATOR

Consider a randomized controlled trial with N units indexed by $i = 1, \ldots, N$. Treatment assignments $tr_i \in \{0, 1\}$ are independent across units, with $P(tr_i = 1) = p_i \in (0, 1)$. For each unit, we observe outcome Y_i and covariates Z_i. Under the potential outcomes framework [8], unit i has potential outcomes t_i and c_i, and the observed outcome is $Y_i = tr_i t_i + (1 - tr_i)c_i$. The individual treatment effect is $\tau_i = t_i - c_i$, and the average treatment effect is $\bar{\tau} = \frac{1}{N}\sum_{i=1}^{N} \tau_i$.

2.1 Leave-One-Out Potential outcome

Define the counterfactual expected outcome as $m_i = (1 - p_i)t_i + p_i c_i$, with estimate $\hat{m}_i$. Let the inverse probability weight be $U_i = \frac{1}{p_i}$ if $tr_i = 1$ and $U_i = \frac{1}{1-p_i}$ if $tr_i = 0$. The unit-level estimator $\hat{\tau}_i = (Y_i - \hat{m}_i)U_i$ is unbiased for τ_i when $\hat{m}_i$ is independent of tr_i [14]. The average treatment effect is estimated by $\hat{\tau} = \frac{1}{N}\sum_{i=1}^{N} \hat{\tau}_i$, and the estimator has bounded variance when $\hat{m}_i \approx m_i$ [14].

In practice, $\hat{m}_i$ is obtained via leave-one-out prediction: for each unit i, a model trained on the remaining $N - 1$ units produces predictions $\hat{t}_i$ and $\hat{c}_i$, with $\hat{m}_i = (1 - p_i)\hat{t}_i + p_i\hat{c}_i$. Flexible methods such as random forests can capture nonlinearities and interactions while preserving unbiasedness, and naturally provide out-of-bag predictions aligned with this procedure.

2.2 Ordered LOOP

Standard random forest implementations face significant computational challenges when handling high-cardinality categorical predictors. For a predictor with k categories, the classical splitting rule considers $2^{k-1} - 1$ possible partitions, which quickly becomes infeasible even for moderate k. Unlike continuous or ordinal variables, these splits cannot be represented by a single threshold. In practice, implementations often encode category assignments using bit representations, imposing hard limits (e.g., 32 or 64 levels) on the number of supported categories.

A common solution is to impose an ordering on categorical levels. For regression and binary classification, ordering categories by their mean response or class proportion yields the same optimal split as exhaustive search, while reducing the number of candidate splits from $2^{k-1} - 1$ to $k - 1$ [1, 3, 7]. When this ordering is computed once and reused throughout tree construction, splits can be implemented as simple thresholds, leading to substantial computational gains with minimal loss in predictive performance [13].

We adopt the `ranger` implementation, which supports this approach via `respect.unordered.factors = "order"`. In this setting, factor levels are ordered once based on their mean response (for regression) or outcome class proportions (for classification), and are not reordered at each split [5], where "class" refers to the response category rather than classroom groupings.

Incorporating ordered factors into LOOP introduces two challenges. First, the imputed regression function $\hat{m}_i$ must remain independent of each observation's outcome. To ensure this, we use K-fold cross-fitting: the data are randomly partitioned into K folds, and for each fold, separate models are trained on the remaining $K - 1$ folds for the treated and control groups. Out-of-fold predictions $\widehat{\mu}_1(tr) = \mathbb{E}[Y(1) \mid tr]$ and $\widehat{\mu}_0(tr) = \mathbb{E}[Y(0) \mid tr]$ are then obtained for the held-out observations.

Second, arm-specific K-fold training can produce categorical levels in the test fold that are absent from the corresponding training data, leading to unstable predictions under ordered encoding. To address this, we adopt a row-level fallback strategy: for observations with unseen levels, we use predictions from a numeric-only imputation model (standard LOOP), while retaining ordered-`ranger` predictions for all other observations.

This hybrid approach leverages high-cardinality categorical information while ensuring stability and preserving the flexibility and unbiasedness of the LOOP estimator. When high-cardinality categorical variables are informative about the outcome, Ordered LOOP can exploit the induced ordering structure to reduce variance, effectively lowering the standard error and improving precision relative to standard LOOP. In settings where such structure is weak or absent, its performance remains comparable to LOOP.

3. SIMULATION DESIGN

Evaluating treatment effect estimators requires ground truth, which is unavailable in real experiments. We therefore simulate realistic settings using *remnant* [4, 9, 10] logs, which consist of observational student–assignment records aligned with experimental contexts.

3.1 Focal Measures

We use three variables: (i) student performance (inverse mastery speed, bounded in $[0, 1/3]$, with 0 indicating non-completion [2]), (ii) prior performance (prior percent correct), and (iii) class membership (de-identified classroom ID).

3.2 Data Generation

We generate synthetic A/B tests using a bootstrap-style resampling procedure applied to the remnant data. This approach preserves the empirical distributions of class sizes, class-level heterogeneity, and student-level noise, while allowing controlled specification of treatment effects and outcome models.

We consider two data-generating processes. First, we replicate the baseline design of Closser et al. [2]. Second, we construct a more realistic setting in which class membership interacts with covariates and induces nonlinear outcome relationships. In this setting, standard fixed- and random-effects models are misspecified, allowing us to assess whether flexible machine learning methods can better capture the underlying structure.

3.2.1 Linear relationship

Under the linear specification, outcomes are generated as

$$\begin{aligned}\text{true_outcome} = \text{class_coef} + 0.16 \times \text{prior_percent_correct} \\ + \text{effect_size} \times \text{condition} + \eta. \end{aligned} \quad (1)$$

Parameters are calibrated from the remnant data. We fit three models relating inverse mastery speed to prior percent correct: (i) OLS, (ii) OLS with class fixed effects, and (iii) a mixed-effects model with class-level random intercepts. The class-specific intercepts from the fixed-effects model define class_coef, capturing empirical classroom heterogeneity without imposing distributional and independence assumptions. The coefficient on prior performance is set to the average estimate across the three models (0.16).

Student-level noise η is generated by resampling residuals from the mixed-effects model, which provides a parsimonious decomposition of within- and between-class variation.

Each simulated dataset is constructed by sampling n_{classes} classrooms with replacement from the remnant data and retaining all associated observations. For each classroom, we draw a class-specific effect by resampling from the empirical distribution of the estimated class-level coefficients class_coef obtained from the observed data.

At the observation level, we resample η and assign treatment independently with probability 0.5. Outcomes are then generated according to Equation (1).

3.2.2 Nonlinear relationship

Under the nonlinear specification, we introduce a class-relative threshold effect,

$$\begin{aligned}\text{true_outcome} = \text{class_coef} + 0.16 \times \text{prior_percent_correct} \\ - I\{\text{prior_percent_correct} > \text{class_coef}\} \\ + I\{\text{prior_percent_correct} < \text{class_coef}\} \\ + \text{effect_size} \times \text{condition} + \eta. \end{aligned} \quad (2)$$

This component captures class-relative dynamics in which outcomes depend on a student's performance relative to the class baseline. Higher-performing students may experience smaller gains (e.g., ceiling effects), while lower-performing students may benefit more from instruction, inducing a nonlinear pull toward the class mean.

Overall, this simulation framework preserves key empirical features of the remnant data while enabling controlled comparisons of estimator performance under both linear and nonlinear outcome-generating mechanisms.

4. RESULTS

The models evaluated in this study are summarized in Table 1 and are selected to address our central question: whether and how treatment effect estimation should account for the clustering of students within classrooms. We consider three classes of methods. First, we include approaches that ignore classroom structure, namely the two-sample t test and standard LOOP; the latter cannot incorporate classroom indicators when the number of categories is large (e.g., more than 53 levels). Second, we examine parametric models with fixed or random intercepts. Third, we evaluate Ordered LOOP, a machine-learning approach that flexibly captures classroom heterogeneity. Our goal is to assess when Ordered LOOP improves upon these alternatives.

4.1 Simulation Studies

All simulations fix the true treatment effect at 0.2 and are repeated 100 times.

4.1.1 Linear setting.

Table 2 reports results under the linear data-generating process. All methods recover the true effect accurately, but differ in precision. Methods that account for classroom structure achieve smaller standard errors than those that ignore it.

The random-effects model achieves the lowest variance, as expected under correct model specification. Ordered LOOP ranks second, indicating that it remains competitive even when the true outcome model is linear and fixed- or random-effects models are correctly specified.

In contrast, the standard LOOP estimator with covariate adjustment performs worse than the baseline t test. To better understand this result, we examined the imputation step $\hat{m}$ in LOOP and found that the random forest used for outcome prediction explains a negative proportion of the outcome variance (-25.02%). This indicates that the prediction model fails to capture useful signal in this setting, which in turn explains why covariate adjustment through LOOP does not improve—and in fact degrades—performance relative to the simple t test.

Overall, in the linear scenario, our findings are consistent with those of Closser et al. [2]: methods that explicitly account for classroom structure outperform approaches that ignore group-level heterogeneity, even when treatment is randomized at the student level. At the same time, Ordered LOOP remains a competitive alternative without requiring parametric assumptions about classroom effects.

4.1.2 Nonlinear setting.

Table 3 summarizes results under the nonlinear data-generating process. In this setting, parametric models are misspecified, and performance differences become more pronounced.

All methods recover the true effect accurately again. Ordered LOOP achieves the lowest standard error, followed by standard LOOP, demonstrating the advantage of flexible machine learning methods in capturing nonlinear and interaction effects. In contrast, fixed- and random-effects models are less efficient due to model misspecification.

Notably, standard LOOP performs well despite not explicitly including classroom indicators, suggesting that flexible modeling can partially compensate for missing group structure. However, incorporating classroom information through Ordered LOOP yields additional gains.

Across both settings, accounting for classroom structure consistently improves precision. Ordered LOOP performs ro-

Table 1: Modeling methods overview

Method	Equation	Assumptions
t-test	$Y_{ij} = \beta_0 + \beta_1 tr_{ij} + \epsilon_{ij}$	$\mathbb{E}(\epsilon_{ij} \mid tr_{ij}) = 0$
OLS + fixed class intercepts	$Y_{ij} = \beta_{0j} + \beta_1 tr_{ij} + \beta_2 Z_{ij} + \epsilon_{ij}$	$\mathbb{E}(\epsilon_{ij} \mid tr_{ij}, Z_{ij}, \text{Class}_j) = 0$
HLM + random class intercept	$Y_{ij} = \beta_{0j} + \beta_1 tr_{ij} + \beta_2 Z_{ij} + \epsilon_{ij}$ where $\beta_{0j} = \gamma_{00} + \eta_j$	$\epsilon_{ij} \sim \mathcal{N}(0, \sigma)$ and $\eta_j \sim \mathcal{N}(0, \tau)$
LOOP	$\hat{\tau} = \frac{1}{N} \sum_{i=1}^{N} \hat{\tau}_i$ where $\hat{\tau}_i = (Y_i - \hat{m}_i)U_i$ ignoring classes	Unbiased with good precision when $\hat{m}_i \perp U_i$ and $\hat{m}_i \approx m_i$
Ordered LOOP	Same as LOOP while $\hat{m}_i$ is estimated using ordered random forests in `ranger` with classes	Same as LOOP

Table 2: Average treatment effect estimates and standard errors under the linear outcome model.

Method	t-test	FE	RE	LOOP	Ordered LOOP
Estimate	0.1995	0.1995	0.1994	0.1992	0.1994
Std.Error	0.0030	0.0029	**0.0025**	0.0033	**0.0028**

Note: Lowest standard errors are shown in bold.

Table 3: Average treatment effect estimates and standard errors under the nonlinear outcome model.

Method	t-test	FE	RE	LOOP	Ordered LOOP
Estimate	0.2003	0.2003	0.2003	0.1995	0.1996
Std.Error	0.0063	0.0059	0.0050	**0.0041**	**0.0033**

bustly, remaining competitive in linear settings and outperforming alternatives in nonlinear settings, highlighting its effectiveness across both simple and complex outcome-generating processes.

4.2 Real-World Applications

4.2.1 Remnant data application

We construct a semi-synthetic dataset by assigning treatment at random, $tr_i \sim$ Bernoulli(0.5), since the remnant data contain no real treatment. Results are reported in Table 4. As expected, all estimates are close to zero.

Table 4: Average treatment effect estimates and standard errors on remnant data.

Method	t-test	FE	RF	LOOP	Ordered LOOP
Estimate	-0.0004	-0.0002	-0.0002	−0.0001	−0.0000
Std.Error.	0.0016	**0.0015**	**0.0014**	0.0016	**0.0015**

Table 4 shows that methods accounting for classroom structure outperform those that ignore it: the hierarchical linear model achieves the smallest standard error, followed by Ordered LOOP and OLS with classroom fixed effects. Ordered LOOP is unbiased by construction, whereas the random-effects model relies on distributional assumptions that may not hold in practice.

4.2.2 LLM-based experiment.

We further evaluate all methods on a real experiment involving GPT-4–generated explanations [12]. Results are reported in Table 5.

Table 5: Average treatment effect estimates and standard errors on LLM-generated data.

Method	t-test	FE	RE	LOOP	Ordered LOOP
Estimate	0.0163	0.0083	0.0065	0.0102	0.0086
Std.Error	0.0083	0.0083	0.0112	0.0082	**0.0078**

The point estimates differ across methods, and because this is a real A/B test, the true effect is unknown. Theoretically, the t-test, fixed-effects model, LOOP, and Ordered LOOP are unbiased, while the random-effects model may be biased under misspecification.

Accounting for classroom clustering generally improves precision, but model misspecification can substantially increase variance. Ordered LOOP achieves the lowest standard error, outperforming the t-test baseline (0.0078 vs. 0.0083). In contrast, the random-effects model exhibits the largest variance, with a standard error 44% higher than that of Ordered LOOP (0.0112 vs. 0.0078), likely due to misspecification of its underlying assumptions. This illustrates a key limitation of parametric approaches: when the true data-generating process is unknown, misspecification can reduce robustness and lead to poorer performance. In contrast, more flexible, machine-learning–based methods that rely less on parametric assumptions tend to produce more stable and efficient estimates in such settings.

Across simulations and real data, two patterns emerge: accounting for classroom structure improves efficiency, and Ordered LOOP provides a robust and flexible approach that matches correctly specified parametric models and outperforms them when such models are difficult to specify. We therefore recommend Ordered LOOP for reliable performance across a wide range of settings.

5. DISCUSSION AND CONCLUSION

We study treatment effect estimation in online educational experiments with student-level randomization, focusing on classroom-level heterogeneity. Across simulations and real-world applications, methods that account for classroom structure, including fixed effects, random effects, and Ordered LOOP, consistently outperform those that ignore it, indicating that randomization alone may be insufficient for precise estimation.

When classroom effects are approximately linear, fixed- and random-effects models perform best under correct specifi-

cation [2]. However, when effects are nonlinear or interact with covariates, parametric models may be misspecified and lose efficiency. In such settings, Ordered LOOP flexibly captures complex relationships while remaining competitive in simpler cases and retaining interpretability for estimating the average treatment effect.

Overall, accounting for clustering is essential for precision. Ordered LOOP offers a robust and flexible approach without requiring strong parametric assumptions. Future work could combine LOOP-style imputation with parametric models to further improve efficiency and interpretability.

ABSTRACT

The automation of systematic reviews (SRs) with large language models (LLMs) offers substantial potential to reduce the labor-intensive demands of manual screening. Yet, single-agent LLMs are prone to unilateral bias and critical omissions (false negatives), particularly when dealing with the contextualized and often subjective constructs characteristic of educational research. This study proposes a heterogeneous dual-agent, consensus-seeking workflow that emulates human double-blind screening followed by inter-coder reconciliation. Using DeepSeek-V3.2 and Qwen3.5-35B as independent screening agents, the system first conducts separate title–abstract evaluations and then applies an automated negotiation mechanism to resolve disagreements. Tested on a dataset of 2,107 articles extracted from the Web of Science across five SRs, the multi-agent framework successfully outperformed both single-agent baselines in accuracy, recall, and F2 scores. Concurrently, it maintained strong workload reduction, accurately excluding 81% of irrelevant records from human review. Variance analyses further demonstrated that the debate mechanism improved the stability of screening performance across heterogeneous data subsets. Although the absolute performance metrics remain moderate—highlighting the inherent difficulty of fully automating literature screening for complex constructs—these preliminary findings provide promising empirical support. They establish multi-agent collaboration as a more rigorous and reliable paradigm for advancing LLM-assisted evidence synthesis in education.

1. INTRODUCTION

A literature review, as a scholarly paper, provides an overview of current knowledge on a given topic by summarizing and synthesizing the substantive findings of existing research, as well as highlighting theoretical and methodological contributions [13]. Accordingly, literature reviews serve to establish what is known and unknown about a particular phenomenon and to identify areas where further research is required. Based on differences in their search and analysis characteristics, literature reviews can be classified into several types, including rapid reviews, scoping reviews, systematic reviews, meta-analyses, and umbrella reviews, among others [8].

Among these, systematic reviews are among the most frequently employed approaches. They aim to collate all empirical evidence that meets pre-specified eligibility criteria in order to answer specific, clearly formulated research questions [2]. By employing explicit and reproducible systematic methods—such as the PRISMA framework [15])—systematic reviews seek to minimize bias and provide reliable findings from which conclusions can be drawn and informed decisions made. Due to their transparency, accountability, and replicability, systematic reviews have gained increasing popularity within the field of education.

Typically, systematic reviews involve a standardized set of procedures. Retrieved studies are screened for eligibility using predetermined inclusion and exclusion criteria, a process strictly requiring at least two human reviewers working independently to ensure reliability and mitigate individual bias [16]. However, it has been found that conducting a systematic review takes approximately 67 weeks from registration to publication [3]. In research areas characterized by rapid technological change, such a prolonged timeframe may render an unpublished systematic review outdated. Consequently, researchers have begun exploring automated methods to replace human effort in the labor-intensive screening phases [12].

The emergence of large language models (LLMs) presents promising opportunities to expedite this process. Recently, [6] systematically evaluated 18 different LLMs for title-and-abstract screening, demonstrating their substantial potential to reduce workload. However, their findings also highlighted significant variability among models; relying on a single LLM (a single-agent approach) often yields inconsistent accuracy, risking the exclusion of relevant studies or the over-inclusion of irrelevant ones. Furthermore, assigning a single LLM to conduct the screening fundamentally violates the methodological requirement of having multiple independent reviewers, raising concerns about the dependability and credibility of the automated screening process.

To address the limitations of single-agent approaches, recent advancements in qualitative data analysis have introduced multi-agent systems (MAS) (e.g., [17, 18]. In a multi-agent framework, multiple LLMs are instantiated with distinct roles, allowing them to collaborate, cross-verify, and engage in social behaviors such as debating and consensus-seeking [1, 26]. By simulating human collaborative workflows, multi-agent systems can effectively reduce the inherent biases and hallucinations of individual models, yielding far more robust and rigorous analytical outcomes.

Despite these advancements, there is a lack of empirical research examining the application of multi-agent LLM systems to systematic reviews, particularly within the education domain. It remains unclear whether simulating the human dual-reviewer workflow using heterogeneous LLMs (i.e., different underlying models acting as independent coders) can resolve the inconsistency issues identified in prior studies. Therefore, in this preliminary study, we aim to investigate the effectiveness of leveraging a multi-agent framework to facilitate the title-abstract screening process for educational systematic reviews. Specifically, we employ distinct LLMs to act as independent coders, evaluating their individual screening performance and their ability to reach a consensus through simulated inter-coder discussion, thereby paving the way for a more reliable, automated approach to evidence synthesis.

2. RELATED WORK

2.1 LLMs and Multi-Agent Systems in Qualitative Research

LLMs are increasingly utilized in qualitative data analysis (QDA). Early research explored single LLMs as research assistants, demonstrating their ability to simulate thematic analysis [5] and develop codebooks in educational contexts [25, 11]. While single-agent approaches improve efficiency and clarify coding definitions [25], their performance heavily depends on prompting strategies and construct complexity [11, 22, 21, 23]. Furthermore, they remain susceptible to inherent biases and hallucinations when processing complex logic.

To overcome these limitations, research is shifting toward LLM-based multi-agent systems (MAS). By assigning specific roles to different LLMs, MAS can automate complex workflows. For example, [18] utilized task-specific agents for text summarization and theme extraction, showing that this "division of labor" accelerates QDA and ensures analytical validity by approximating the rigor of human research teams.

Crucially, MAS can simulate human "triangulation" and peer-review processes via built-in collaboration. Introducing "debate" and "reflection" workflows enables agents to exhibit consensus-seeking behaviors and reach agreements through negotiation [26, 4]. In thematic analysis, employing multi-agent collaboration (e.g., independent coder roles) significantly enhances the credibility and dependability of findings compared to single agents [17]. Collectively, these mechanisms are critical for improving the rigor of automated QDA.

2.2 Automating Systematic Reviews via LLM Agents

LLMs also present opportunities to accelerate the highly time-consuming systematic review (SR) process, alleviating the burden of manual screening and data extraction. Despite methodological challenges like model bias and hallucinations, researchers are exploring end-to-end automated systems that integrate screening and bias assessment functionalities.

For title and abstract screening, single LLMs show promise but yield mixed results. While GPT-4 achieved a 100% recall rate in environmental science SRs [14], studies evaluating multiple cutting-edge models in medical SRs noted significant discrepancies in false negative and positive rates, alongside substantial instability in identifying relevant literature [19, 6]. Furthermore, extraction accuracy for complex variables remains highly domain-dependent [9].

Despite this potential, two salient research gaps remain. First, the efficacy of LLMs for SRs in the education domain is underexplored. Unlike objective clinical metrics, educational literature involves highly contextualized and subjective constructs, leaving it unclear whether LLMs can reliably apply complex inclusion/exclusion criteria here. Second, most automated SR research relies on single-agent frameworks. This unilateral decision-making is susceptible to inherent biases and fundamentally violates the SR methodological requirement of having at least two independent reviewers. It remains unknown whether a multi-agent system—simulating human dispute discussion and consensus-seeking through independent LLM coders—can surpass single agents. Consequently, empirical research is needed to validate the feasibility of multi-agent collaborative architectures for title-abstract screening in educational SRs.

3. METHOD

3.1 Data Source

In this preliminary study, we searched Computers & Education—a leading journal in the field of education—for systematic reviews with titles containing the phrase "systematic review". Our initial goal was to replicate the literature search process by adhering to the search strategies described in these systematic reviews. However, we found that many reviews did not specify the exact search date, making replication challenging. Additionally, for some systematic reviews, even when we strictly followed the reported search strategies, our search results did not correspond with those presented

Table 1: Five systematic reviews whose literature search was replicated in our study.

Reference	Topic	# Total studies identified in WoS	# Included WoS studies
[7]	Immersive virtual reality serious games for evacuation training and research	249	9
[10]	Speech-recognition chatbots for language learning	235	49
[20]	Computational thinking through programming in K-12 education	643	59
[24]	Teaching and learning robotics content knowledge in K-12 education	373	6
[27]	Impact of esports participation on the development of 21st century skills in youth	607	49

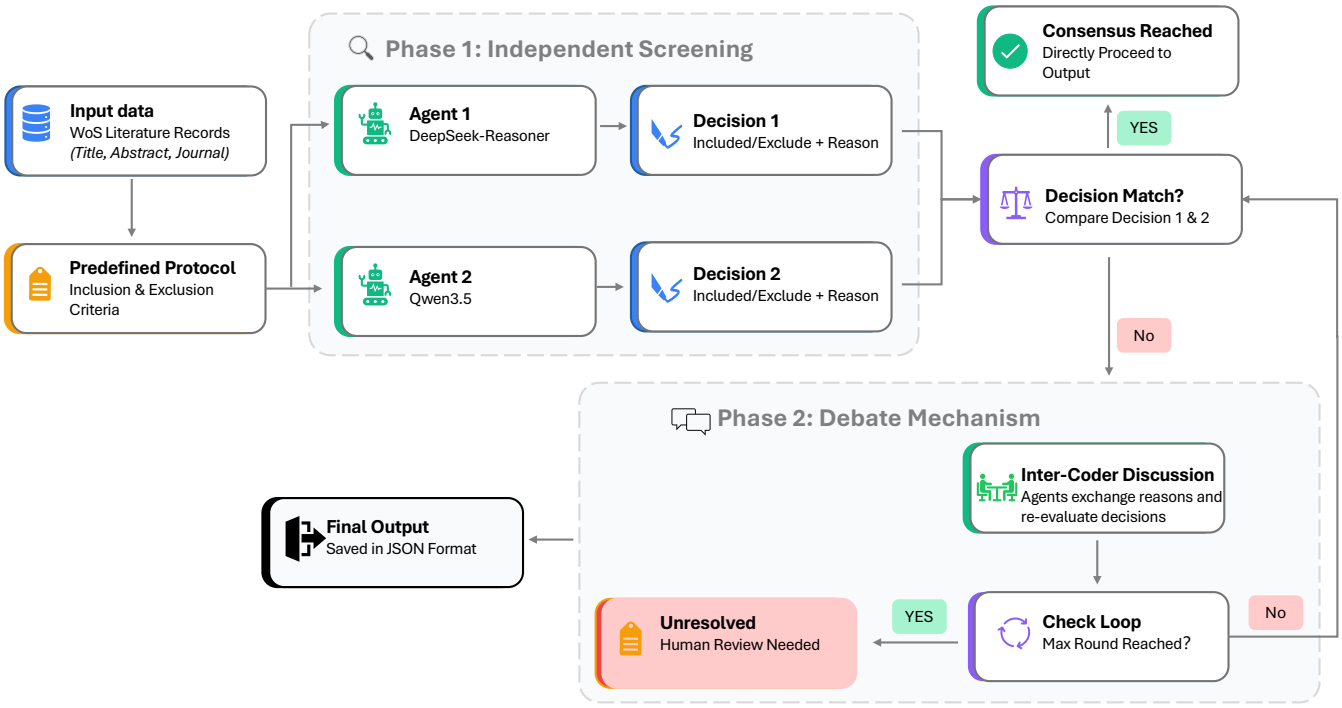

Figure 1: A dual-agent consensus-seeking workflow for systematic literature screening.

in the articles. Consequently, we revised our approach: we limited our analysis to systematic reviews that clearly reported both their search strategies and search dates. We also acknowledged that some variation between our search results and those reported in the articles was likely.

To avoid duplicate records from multiple databases, we restricted our search to the Web of Science (WoS) database. Ultimately, we selected five systematic reviews for this exploratory and preliminary study and replicated their literature search results using WoS. Table 1 summarizes the basic information for these reviews, including their topics, the total number of studies identified in WoS, and the number of WoS studies ultimately included in each review.

3.2 A dual-agent consensus-seeking workflow for systematic literature screening

In this study, we designed a dual-agent consensus-seeking workflow to simulate the rigorous human double-blind screening process for systematic literature reviews, as illustrated in Figure 1. To perform the title-abstract screening, we instantiated two distinct agents powered by heterogeneous large language models (i.e., DeepSeek-V3.2 and Qwen3.5-35b).

In Phase 1, the two agents independently coded each article and generated unilateral decisions regarding its inclusion or exclusion for subsequent full-text review. Both agents were governed by a unified system prompt that assigned them the persona of an expert academic researcher conducting a preliminary systematic review screening. Through zero-shot prompting, the models were provided with strict inclusion and exclusion criteria alongside a standardized output format (e.g., JSON). Importantly, to facilitate an objective evaluation of our workflow's efficacy, these screening criteria were directly extracted from the previously published systematic review. This design choice ensured an unbiased benchmark, allowing us to evaluate the agents' performance

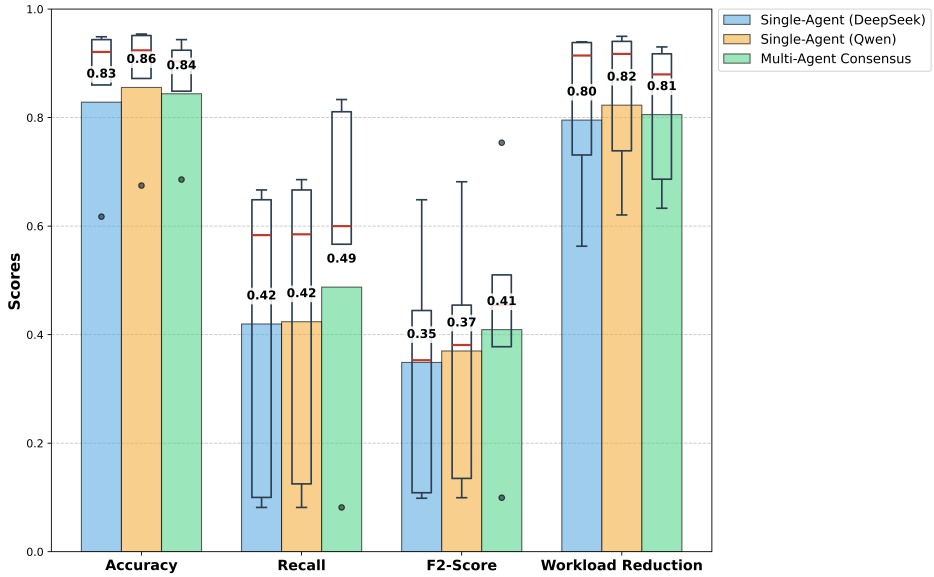

Figure 2: The aggregated global performance (represented by the bar heights) alongside the cross-sectional variance across the five systematic review (illustrated by the overlaid boxplots).

against an established human-coded ground truth.

In Phase 2, the workflow automatically cross-verified the decisions generated by the two agents. If a consensus was reached (i.e., both agents agreed to include or exclude), the final decision was recorded, and the system proceeded to the next article. However, in the event of a disagreement, the debate mechanism was triggered. During a debate round, each agent was provided with the counterpart's previous decision and rationale, prompting them to reflect, cross-examine the discrepancies, and re-evaluate their own stance. If this inter-coder discussion led to a consensus, the loop terminated successfully. If the conflict persisted, the agents engaged in further debate iterations until a predefined maximum number of rounds (i.e., $N = 3$ in our study) was reached. Articles that remained unresolved after the maximum debate rounds were flagged for human intervention by a senior researcher, perfectly mirroring the standard dispute-resolution protocol of traditional systematic reviews.

3.3 Evaluation

To rigorously evaluate the performance of the single-agent baselines (Phase 1) against the multi-agent consensus framework (Phase 2), we compared the classification decisions generated by DeepSeek and Qwen against the human-annotated ground truth (i.e., the ultimate inclusion or exclusion decisions established by the original systematic review).

Given the highly imbalanced nature of title-abstract screening in systematic reviews—where negative samples (excluded articles) vastly outnumber positive ones—we employed four specific evaluation metrics: Recall, F2-Score, Accuracy, and Workload Reduction. Recall calculates the proportion of genuinely relevant studies successfully identified for inclusion. This metric is paramount in our context, as minimizing the omission of relevant literature (i.e., false negatives) is the primary objective of automated screening. To comprehensively evaluate the model's discriminative power while heavily penalizing missed articles, we utilized the F2-Score, which assigns twice the weight to recall compared to precision. Accuracy measures the overall proportion of studies correctly classified by the agents. Finally, Workload Reduction quantifies the practical utility of the automated system by calculating the proportion of total retrieved articles that were correctly excluded (true negatives), reflecting the actual human screening effort saved.

4. PRELIMINARY RESULTS

Due to page limits, Figure 2 reports the aggregated global performance (bar heights) together with the cross-sectional variance across the five independent data chunks (overlaid boxplots).

As shown in Figure 2, the Multi-Agent Consensus system clearly outperformed the single-agent baselines in identifying positive samples. The dual-agent debate mechanism achieved the highest global Recall of 0.49, outperforming both DeepSeek (0.42) and Qwen (0.42). This 16.6% relative improvement suggests that the inter-coder discussion and re-evaluation phase successfully recovered false negatives that were initially missed under unilateral decision-making. Consistent with this pattern, the multi-agent system also obtained the highest F2-score (0.41), compared with DeepSeek (0.35) and Qwen (0.37).

Although Recall was the primary objective, the automated system must also substantially reduce human screening effort. For Workload Reduction, all three configurations performed strongly, effectively filtering out irrelevant records. The Multi-Agent system achieved a Workload Reduction of 0.81 (i.e., safely excluding 81% of all articles from human review), closely comparable to Qwen (0.82) and DeepSeek (0.80). Overall Accuracy ranged from 0.83 to 0.86 across models, indicating a consistently strong ability to identify

true negatives in the highly imbalanced dataset.

The overlaid boxplots in Figure 2 also highlight the intrinsic challenges of automated screening in subjective, imbalanced educational datasets. Accuracy and Workload Reduction exhibited compact interquartile ranges, indicating stable performance across the five data chunks. In contrast, Recall and F2-score displayed larger variability, suggesting that model sensitivity is context-dependent and fluctuates with the specific subset of literature. Notably, however, the Multi-Agent Consensus system raised the median Recall (red line within the box) to approximately 0.60, higher than both single-agent baselines. This upward shift in the median distribution provides additional evidence that the debate mechanism not only improves global performance but also enhances the robustness of screening across heterogeneous samples.

Despite these promising results, 92 studies in the corpus still failed to reach a consensus after three discussion rounds.

5. DISCUSSION

This study proposed a dual-agent consensus-seeking workflow to automate title-abstract screening in educational systematic reviews. Our preliminary findings demonstrate that simulating a human-like inter-coder debate significantly improves global Recall (0.49) and F2-Score compared to single-agent baselines (0.42), while successfully reducing the human screening workload by over 80%. This performance gain highlights the effectiveness of the multi-agent debate mechanism in rectifying unilateral LLM biases and rescuing critical false negatives.

Despite these improvements, the absolute Recall of approximately 50% indicates that fully autonomous LLM screening remains challenging in the education domain. We attribute this to the highly contextualized and subjective nature of educational constructs. Unlike explicit clinical metrics in medical reviews, educational inclusion criteria (e.g., "21st-century skills" or "pedagogical integration") often require nuanced, human-level interpretative reasoning that zero-shot prompting struggles to fully capture. Thus, future iterations should incorporate few-shot prompting with human-annotated examples to calibrate the agents' sensitivity.

ABSTRACT

AI agents that support collaborative learning must model the phenomena that drive productive group work, including communicative acts, belief formation, trust dynamics, and reasoning quality, as they unfold in real time. Existing collaborative datasets capture idealized cooperation under shared epistemic goals, but the dynamics pervasive in real classrooms, such as misconceptions, unreliable contributions, overconfident errors, and their downstream effects on group reasoning, remain largely absent and unlabeled. We propose social deduction games, specifically Secret Hitler, as a proxy testbed where collaborative problem solving and controlled injection of unreliable information co-occur with researcher-accessible ground truth. The game's role structure produces contributions that are functionally equivalent to classroom misconceptions and misdirection, but with known provenance, enabling traceable study of how unreliable information propagates through groups. We present a multi-layer annotation framework that captures communicative acts using a validated persuasion strategy taxonomy, player-reported belief states yielding first- and second-order Theory of Mind data, and post-hoc epistemic vigilance assessments of whether belief updates were warranted given available evidence. We pair this framework with multi-person egocentric sensing using Meta Aria research glasses alongside exocentric recording, providing synchronized capture of gaze, attention, and social signals from every participant's perspective. Pilot data from two 6-player, 9-round sessions demonstrates that failed epistemic vigilance, belief fragmentation, and traceable misinformation effects emerge naturally and are captured by the framework.

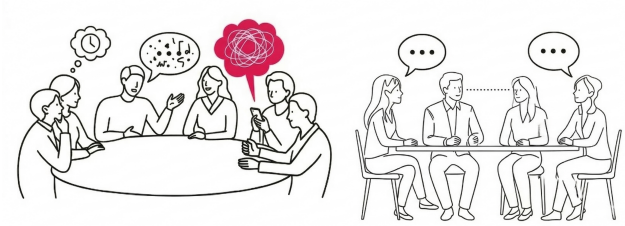

Figure 1: Real collaboration (left) involves heterogeneous contributions, competing attention, and participants who may be disengaged or misinformed—dynamics pervasive in collaboration but largely absent from controlled datasets. Idealized settings (right) capture only cooperative interaction. Our testbed produces the dynamics on the left with the ground truth needed to study them.

1. INTRODUCTION

AI agents that facilitate collaborative learning must model the phenomena that drive productive group work as they unfold: the *communicative acts* members perform, the *beliefs* they hold and revise, the *reasoning quality* with which they evaluate one another's contributions, and the *trust dynamics* that determine whose voice carries weight [2, 15, 18]. Developing models that capture these phenomena requires extensive iteration on sensing, annotation, and inference that would consume scarce instructional time if conducted in classrooms. Instead, we need proxy testbeds: controlled environments where groups collaborate naturally, producing multimodal signals (speech, gaze, gesture, posture), but where data collection serves system development rather than student learning.

Existing testbeds such as the DELI corpus [9] and Physics Playground [18] capture multi-party deliberation and collaborative problem solving (CPS), but under shared epistemic goals where all participants work toward the right answer. Real collaboration is messier: students unknowingly spread misconceptions, assert incorrect solutions with unwarranted confidence, freeload, or dominate discussions unproductively [4]. These dynamics of *unreliable contributions*—not intentional sabotage, but the natural heterogeneity of contributor quality—are pervasive in classrooms [10, 14] yet rare in existing datasets.

We propose social deduction games, specifically *Secret Hitler*,

as a proxy testbed that fills this gap. Players are secretly assigned to cooperative or disruptive teams and engage in structured rounds of discussion, voting, and policy enactment. For the majority of players, the game *is* collaborative problem solving: pooling incomplete evidence, evaluating reliability of claims, and coordinating decisions under genuine uncertainty about who is trustworthy [15, 18]. What makes the setting valuable is that a minority of players are structurally incentivized to introduce unreliable information—spreading misinformation, asserting false claims with confidence, and undermining group reasoning. These contributions are *functionally equivalent* to the misconceptions, overconfident errors, and unproductive dominance documented in classroom groups [3]: the collaborative challenge they pose is the same, even though the underlying intent differs. Crucially, every piece of unreliable information has known provenance (role assignments provide ground truth), and its effects on group beliefs are traceable through our annotation framework.

We introduce a multi-layer annotation framework targeting progressively deeper social-cognitive constructs. Layer 1 classifies communicative acts using a validated persuasion strategy taxonomy [11]. Layer 2 collects player-reported belief states after each round, yielding first- and second-order Theory of Mind data grounded in Baker et al.'s [2] framework. Layer 3 infers epistemic vigilance post-hoc [16], the capacity to evaluate communicated information for source reliability and content plausibility rather than accepting it uncritically, assessing whether belief updates were warranted given available evidence. The cascading structure of communicative act → belief update → vigilance assessment—captures the trajectory from speech to social-cognitive outcome that a classroom agent must track. We pair this framework with multimodal sensing using Meta Aria egocentric research glasses [7], instrumenting every player to capture synchronized video, eye tracking, and inertial data from first-person perspectives.

Our contributions are:

- A multi-layer annotation framework integrating communicative act classification, player-reported belief states (first- and second-order Theory of Mind), and post-hoc epistemic vigilance inference for coding group social-cognitive dynamics.
- A positioning of Secret Hitler as a CPS environment with controlled injection of unreliable information with known provenance, addressing a gap left by datasets capturing only idealized cooperation.
- Pilot data from two 6-player sessions demonstrating that failed vigilance, belief fragmentation, and traceable misinformation effects emerge naturally and are captured by the framework.

2. SECRET HITLER AS A CPS TESTBED

In Secret Hitler, 5 to 10 players are secretly assigned roles as Liberals or Fascists, with one Fascist designated as Hitler. Each round, a President nominates a Chancellor; the group votes to approve or reject; and if approved, the government enacts a policy from a constrained deck. Liberals win by enacting five Liberal policies or assassinating Hitler; Fascists win by enacting six Fascist policies or electing Hitler as Chancellor.

For the majority of players (Liberals), the game *is* collaborative problem solving: they must externalize private information, build shared representations of the game state, and negotiate coordinated action, all without knowing who their allies are. This maps onto the joint problem space [6, 15, 19] operationalized as "constructing shared knowledge" in the General Competency Model [18]. Critically, the game enforces the information asymmetry that the hidden profile literature identifies as the hardest part of real collaboration [12, 17], a challenge most CPS testbeds sidestep. Discussion phases require players to surface disagreements, provide evidence, and converge on action [3, 8], instantiating the argumentative structure that predicts decision quality [9, 13, 20].

What makes the setting distinctive is not that it introduces dynamics foreign to CPS, but that it makes *visible and labeled* the kinds of unreliable contributions that pervade real collaboration but are rarely captured in research settings. Barron [4] documented how classroom collaborations fail when members push incorrect solutions with unwarranted confidence or dismiss valid contributions. Students regularly spread misconceptions, sometimes unknowingly, sometimes through carelessness and the group's ability to detect and correct these contributions determines whether collaboration succeeds [4]. These dynamics are pervasive [10, 14] yet absent from controlled CPS datasets designed to elicit cooperation under shared goals [18]. Secret Hitler produces functionally equivalent dynamics through its role structure: Fascist players introduce misinformation, assert false claims with confidence, and selectively withhold evidence. The collaborative challenge this poses of forcing the group to evaluating contributions of uncertain reliability, pooling incomplete evidence, and reaching decisions despite misleading information, is the same challenge groups face whenever collaboration involves distributed knowledge and heterogeneous contributor quality. We do not claim that game players are cognitively equivalent to struggling students; we claim that the epistemic problem is shared. The methodological advantage is that the ground truth is known: role assignments let us track who introduced unreliable information, who accepted it (Layer 2), and whether that acceptance was warranted (Layer 3). In a classroom, the same dynamics occur but leave no traceable record.

The testbed also provides structured temporal episodes (nomination → discussion → vote → reveal), rich multimodal interaction in a facetoface small group, and repeatability across sessions. Our annotation framework (Section 3) captures what existing deliberation datasets cannot: the downstream effects of unreliable contributions on *individual* beliefs, traced from specific communicative acts to specific belief changes in specific individuals.

3. MULTI-LAYER ANNOTATION FRAMEWORK

3.1 Multi-Layer Annotation Framework

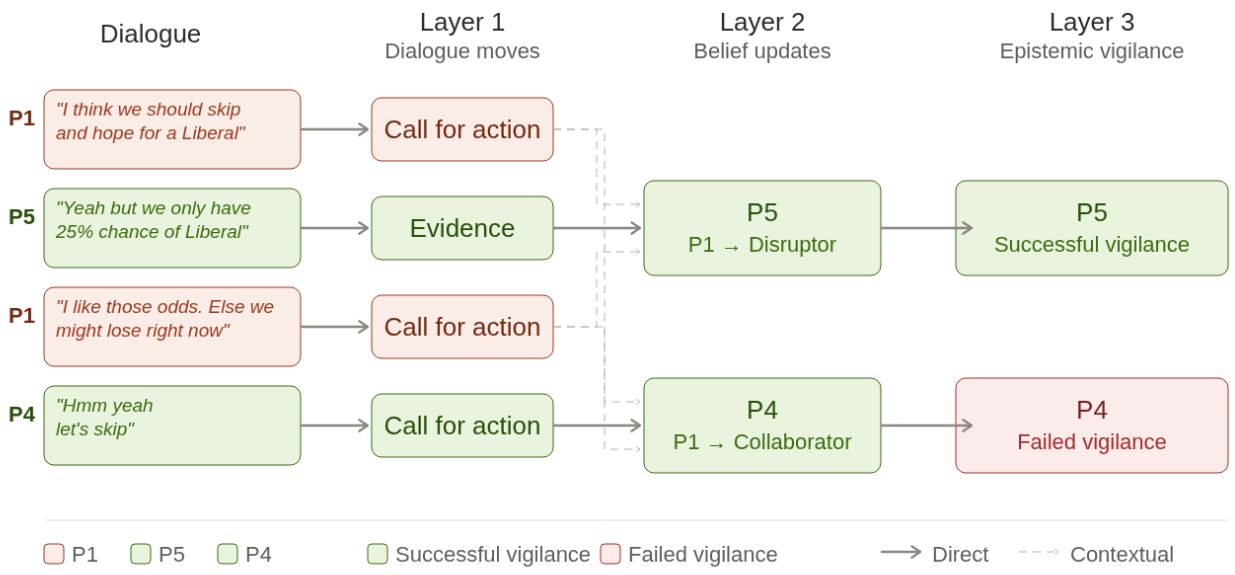

Figure 2: Three layer annotation of a discussion phase. Utterances are classified by communicative function (Layer 1), linked to belief updates (Layer 2), and assessed against ground truth as successful or failed epistemic vigilance (Layer 3). Color indicates true role (red = adversarial, green = collaborative; hidden during play).

The framework is hierarchical: each layer targets a progressively deeper dimension of group social-cognitive dynamics. Layers 2 and 3 operationalize two cognitive science frameworks: Baker et al.'s [2] Bayesian Theory of Mind and Sperber et al.'s [16] epistemic vigilance which have been influential but not previously applied to multimodal behavioral annotation in group settings.

3.2 Layer 1: Communicative Acts

We adopt the six-category taxonomy from Lai et al. [11], annotated at the utterance level: *Identity Declaration*, *Accusation*, *Interrogation*, *Call for Action*, *Defense*, and *Evidence*. This layer captures what communicative act a speaker performs, the information an agent needs to classify conversational moves in real time. Lai et al. report Krippendorff's $\alpha > 0.6$ across all categories, establishing feasibility for reliable annotation.

3.3 Layer 2: Player-Reported Belief States

At the end of each round, players report two types of beliefs:

First-order ToM. Each player records their belief about every other player's role (Liberal, Fascist, or uncertain). Since researchers know the true assignments, these reports yield calibration data: how accurately does each player's belief state track reality as evidence accumulates?

Second-order ToM. Each player records what they think others believe about *their own* role. Comparing Player A's second-order report against Player B's actual first-order report yields a direct measure of Theory of Mind accuracy [2].

These belief reports serve as supervision signals for training models that infer beliefs from observable behavior—gaze patterns, speech acts, voting behavior, and postural cues—since a classroom agent cannot ask students to report beliefs directly.

3.4 Layer 3: Epistemic Vigilance

This layer is inferred post-hoc using Layers 1 and 2 together with ground-truth role assignments [16]. For each communicative act targeting a specific player, we examine the receiver's belief trajectory:

- **Successful vigilance**: belief moved toward truth (e.g., correctly increasing suspicion of a Fascist after inconsistent behavior)
- **Failed vigilance**: belief moved away from truth (e.g., persuaded by a misleading claim, or failing to update when evidence warranted it)

Figure 2 illustrates this cascading structure with an excerpt from a pilot session. P1 (true role: Disruptive) advocates for an irrational move of skipping a turn and hoping for a favorable outcome. P5 correctly objects by presenting evidence that the odds are poor, updating their belief that P1 is a Disruptor showing successful vigilance. P4, however, accepts P1's reasoning and agrees to skip, maintaining the belief that P1 is a trustworthy Collaborator despite the weak justification: failed vigilance. The same exchange thus produces both outcomes in different receivers, and the frame-

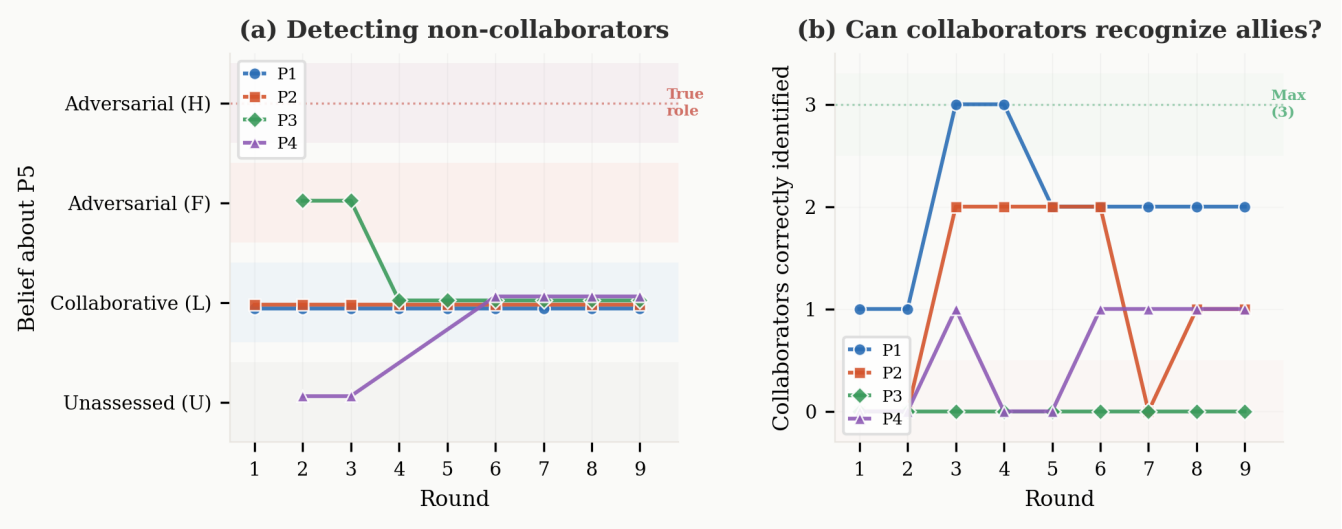

Figure 3: **(a)** Four collaborative players' beliefs about P5 (true role: Disruptive) across rounds. No collaborator ever correctly classified P5. P3 briefly suspected P5 (Rounds 2–3) but reversed by Round 4—a belief update *away* from truth, illustrating failed vigilance. **(b)** Number of fellow collaborators each player correctly identified per round (max = 3).

work captures exactly where and why the group's reasoning diverged.

4. SENSING AND DATA CAPTURE

All players wear Meta Aria Gen 1 research glasses [7], capturing egocentric RGB video, eye-tracking data, and IMU signals. Group audio is recorded via the glasses' microphones, and an overhead camera provides an exocentric reference view. Game state is logged by a facilitator.

Most multimodal learning analytics systems rely on exocentric sensing—ceiling-mounted cameras and external microphones [1]. While scalable, these setups cannot reliably recover participant-relative signals: whether someone is looking *at you*, directing a statement toward you, or attending to the current speaker. Our testbed instruments *every player* with egocentric glasses, producing synchronized capture from all participants' viewpoints. This enables gaze-derived features aligned with our annotation layers: identifying each player's attention target at utterance onset (linking Layer 1 acts to perceptual targets), characterizing gaze sequences during deceptive vs. truthful communication [5], and computing group-level attention divergence across all players at each timestep. Both egocentric and exocentric streams are captured simultaneously, enabling empirical comparison of whether first-person signals carry more information about the social-cognitive constructs in Layers 1–3.

5. PILOT DATA

To demonstrate that the target phenomena emerge naturally, we report observations from a pilot session (6 players, 9 rounds, 2 Disruptive/Adversarial and 4 Collaborative). All players wore Aria glasses and completed belief reports after each round.

Detecting Failed Vigilance. Figure 3(a) tracks collaborative players' evolving beliefs about P5, whose true role was Disruptive. Despite 9 rounds of discussion and evidence, no collaborator correctly identified P5. P3 initially suspected P5 (Rounds 2 and 3) but reversed toward Collaborative by Round 4, constituting *failed vigilance* in our Layer 3 framework: P3 possessed a partially correct signal but abandoned it, likely in response to P5's communicative acts (Layer 1) that undermined the suspicion.

Active but Counterproductive Participation. Figure 3(b) reveals a complementary pattern. P3 correctly identified zero allies across all 9 rounds, placing every collaborator in the Disruptive category—the profile of a group member who is actively reasoning but systematically misdirected. This is analogous to a student who is engaged but whose contributions fragment rather than strengthen shared understanding. Distinguishing active-but-counterproductive participation from constructive collaboration is precisely the capability our Layer 3 assessment operationalizes. P1, by contrast, peaked at identifying all three allies (Rounds 3–4) before declining, suggesting group-level belief fragmentation as unreliable information accumulated.

6. DISCUSSION AND CONCLUSION

The pilot data, though limited to a single session, demonstrates two properties. First, the multi-layer framework produces *linked annotations*: specific communicative acts traced to specific belief changes in specific individuals, assessed for epistemic warrant which is a cascading structure not available in existing CPS [18] or deliberation [9] datasets. Second, the testbed produces unreliable contributions with known ground truth, enabling study of how misinformation propagates through groups and what behavioral signals distinguish listeners who detect it from those who do not.

We frame the testbed as addressing a prior question: is it feasible to infer social-cognitive constructs from multimodal behavioral signals at all? The signals captured here are nat-

uralistic with overlapping speech, occlusions, and rapid gaze shifts, but with clean supervision unavailable in educational settings. We do not claim models trained on game data will deploy directly in classrooms; what transfers is the inference machinery and the insight that proxy testbeds with clean supervision can accelerate model development impractical to iterate on in instructional settings.

7. LIMITATIONS

The pilot comes from a single 6-player session; we do not claim generalizability. Player-reported beliefs are subject to social desirability and retrospective rationalization. Layer 3 assessments depend on binary ground truth cleaner than any classroom would provide. The game's competitive structure may elicit more deliberate reasoning than typical collaboration, and the sensing setup requires research-grade hardware whose value is in model development, not deployment.

ABSTRACT

Low completion rates are a well-documented challenge in MOOCs, and Machine Learning (ML)-based predictors have been proposed as a way to detect at-risk learners and support them through personalised interventions. Yet, evidence shows that ML models trained on such data can be biased against certain groups of learners, often the historically discriminated ones. In particular, usage patterns can substantially vary across world regions due to contextual factors, which can affect predictions. In this work, we analyse ML models trained on a MOOC dataset including African and OECD learners to examine whether, and for whom, biases arise. Our findings show that learners from Middle and Western Africa and from countries with low HDI and low literacy rates are affected by significant biases in ML predictions. Our findings highlight the need to systematically evaluate ML unfairness in African educational contexts.

Fairness, Biases, Machine learning, MOOCs, Africa

1. INTRODUCTION

The widespread adoption of ML in education, e.g., for predicting course success or dropout risk, has raised concerns about their fairness towards historically discriminated groups [7]. ML unfairness arises when model behaviours and accuracy substantially differ across learner groups [8, 21]. When such models guide important decisions like program admission, resource allocation, and interventions for at-risk learners, they risk perpetuating existing biases and hindering the academic outcomes for specific groups of learners [4].

Recent educational data mining research has explored fairness in ML models on educational datasets [3, 10, 11, 26, 29]. Yet, surveys and opinion papers highlight a key limitation: an overwhelming amount of studies focuses on North American and European learners, with few considering African contexts [8, 17, 21]. Yet, African educational contexts have distinctive features, including the high prevalence of mobile or offline learning [16], stark rural-urban contrasts [14], unequal access to connectivity, electricity and computers [16], widespread reliance on open digital spaces and digital universities to mitigate infrastructure limitations [24], decreasing gender parity with higher levels of educational level increases [1], and overcrowded classrooms [12]. These may affect the target population and platform interactions, potentially reflecting contextual constraints rather than learners' engagement, abilities or interests.

Understanding this gap is critical for fairness-aware analysis, particularly in MOOCs which serve international and highly diverse learners, and are widely adopted in Africa [12, 16, 28]. While ML studies to predict drop-out on MOOC data is extensive [2, 18], fairness analyses are scarce [10, 13, 22]. As a result, the promise of democratizing access to knowledge across continents through MOOCs cannot be fully realized if known contextual differences are not accounted for from the course design stage onward. In this respect, indiscriminately combining data from African and Western learners may exacerbate existing biases rather than mitigate them.

Within prior work, the only openly available MOOC dataset used in a fairness study is the GDP-MOOC dataset published by Lallé et al. [13]. This dataset involves students from 23 African countries, mostly located in Western, Northern and Middle Africa. This work [13] showed that ML models can accurately predict MOOC completion, but were biased against African learners. However, they treated all African learners as a single homogeneous group. Building on this, we propose a fine-grained fairness analysis of biases across African countries and socio-economic characteristics in this dataset. Beyond MOOCs, ML biases have been analysed for automatic scoring of Nigerian essays (which accounted for only $< 0.03\%$ of the data) [6], and in the PISA 2015 data, but without specific results for Africa (Al-

geria and Tunisia) [15]. This led to this research question: *Which specific countries or socio-economic characteristics help explain the biases toward Africa of ML models predicting course success in the GDP-MOOC dataset?*

2. METHOD

2.1 Data and Machine Learning Setup

We used the GDP-MOOC open dataset in this paper (`https://github.com/Mocahteam/GdPMOOC_Fairness`) [13]. It originates from a French MOOC on Project Management lasting five weeks (2022 offering) delivered on the OpenEdX platform. The dataset includes weekly aggregated statistical summaries (e.g. counts) derived from OpenEdX log data, the students' country, and their final grade. Course completion (pass/fail) is defined as achieving a final grade of at least 50%. The GDP-MOOC dataset corresponds to the Spring 2022 offering. It includes complete data for 912 learners (460 are in Africa, 452 in OECD countries in Western Europe and North America), among whom 380 (39%) successfully passed the course. Learners provided informed consent for their data to be used for research purposes, and all data are fully anonymized per the EU's General Data Protection Regulation (GDPR).

We replicate the ML pipeline proposed in [13] and shared in their GitHub to train three supervised ML models and predict in a binary way whether learners would *succeed* or *fail* to obtain the certificate at the end of the MOOC. The features used to train the models are the concatenation of weekly action counts f_w^l for each learner $l \in \mathcal{L}$. We train Logistic Regression (LR), Naive Bayes (NB), and Stochastic Gradient Boosting (SGB) on these features, selected respectively for classification performance, fairness, and accuracy–fairness trade-off [13]. We apply learner-level 5-fold stratified cross-validation with feature selection. The full dataset description and ML pipeline are reported in [13], and here we focus on the fairness analysis.

2.2 Bias Analyses

As stated above, ML models trained on the GDP-MOOC dataset exhibited significant unfairness toward African learners [13]. To better characterize these biases, we conduct a subgroup analysis based on the country of African learners (N=460). Their distribution (shown in Table 1) is highly uneven, with the top six countries accounting for over two-thirds of learners and all others having fewer than 20 each. Consequently, we opt to address our research question in two complementary ways: first by focusing on the six countries with over 20 learners (Ivory Coast, DR Congo, Benin, Cameroon, Burkina Faso and Senegal); and second by studying larger groups of countries based on UN-based socio-economic indicators. This second approach highlights higher-level biases that span similar countries. In addition, it allows us to include all of African learners into meaningful and relevant larger analytical groups. The country characteristics (listed in Table 2) are based on five country-level UN-based indicators.

UN Regions: The five sub-regions of Africa defined by the UN Geoscheme, a statistical way to group countries by main geographical areas. This is to understand at the high level whether specific parts of the continent receive more unfair predictions. The data are from the UN Statistical Division[1].

HDI: The four Human Development Index groups as defined by the UN Development Program, a widely accepted way to quantify human development in terms of life expectancy, quality of education, and standard of living. This allows assessing whether ML models perform equitably across contexts with unequal structural opportunities. The HDI groups are based on the Human Development Report for 2022[2].

Literacy: The levels of literacy among adults, as compiled by the UNESCO, which is used as a proxy for the access to fundamental education. The 2022 data are extracted from the IUS Bulk Data[3].

Education: The quality of education (from elementary to university), which is compiled by the UNESCO across a large battery of indicators as part of its Sustainable Development Goals (SDG-4). This is to evaluate whether lower quality of education in a country hinders the overall usage of the MOOCs, and in turn, the fairness of the models. The data are extracted from the IUS Bulk Data[3].

GDI: We consider the Gender Development Index as measured by the UN Development Program, since lower levels of gender development may influence how men and women engage with online learning resources such as MOOCs, potentially affecting ML fairness. Using the raw GDI values, we construct two categories, "low" and "high" GDI, by applying the African median as the cutoff threshold. The data are extracted from the Human Development Report for 2022[2].

We also considered the countries' GDP and access to the Internet, but discarded them as both metrics were highly correlated to the HDI (Pearson $r > .7$).

Fairness metrics. We measure the potential biases across the different groups described in Table 2 through two complementary metrics, namely the group-level AUC, and the MADD. For the first one, we compute the AUC of the models in the test sets for each of the groups, by selecting only learners from a specific group in the test sets (e.g., "West Africa") and computing the AUC of the models' outputs for those learners. This is a simple and commonly used approach to gauge how a model's accuracy varies across groups [10, 21, 23]. For a model to be fair, its AUC should be similar across the different groups of learners. As for the MADD, it leverages the histograms of probabilities output by a model for two groups to compute the areas where the histograms do not overlap [27]. This approach allows to measure how a given characteristics influence the models' outputs, regardless of its performances, as well as toward whom the output probabilities are inflated. To be fair, a models' outputs should not be related to any countries or characteristics it does not know about. Because the MADD involves comparing two groups in a pairwise manner, we use it by comparing each target group against all of the other learners (e.g., "Western Africa" learners vs. everybody else). AUC ranges from 0 (worst performance) to 1 (best performance) and MADD ranges from 0 (fairest) to 2 (most unfair). Both AUC and MADD are independent from

Table 1: Number of learners (n) and passing rates (pr) per African country in the GDP-MOOC dataset.

Country	n (pr)	Country	n (pr)	Country	n (pr)	Country	n (pr)
Ivory Coast	82 (22%)	Togo	16 (31%)	Niger	10 (20%)	Burundi	3 (0%)
DR Congo	74 (36%)	Guinea	14 (14%)	Tchad	10 (3%)	Mauritania	2 (50%)
Benin	60 (40%)	Congo Republic	13 (23%)	Tunisia	9 (22%)	Central African Rep.	2 (0%)
Cameroon	42 (36%)	Mali	13 (8%)	Algeria	8 (38%)	Rwanda	1 (0%)
Burkina Faso	40 (28%)	Gabon	11 (27%)	Madagascar	4 (0%)	Mozambique	1 (0%)
Senegal	33 (27%)	Morocco	8 (38%)	Djibouti	4 (0%)		

Table 2: Country characteristics, sample size per group within Africa and passing rates. We report all groups for completeness, however, only groups with ≥ 20 learners are included in the analysis.

Characteristics	Groups (#learners [passing rate])
Sub-regions of Africa	Northern (25 [32%]), Western (270 [27%]), Eastern (13 [0%]) , Middle (152 [34%]), Southern (0)
HDI	Low (369 [28%]), Medium (63 [33%]), High (28 [29%]), Very high (0)
Literacy	Low (231 [26%]), Medium (155 [33%]), High (41 [27%]), Very high (33 [27%])
Quality of education	Low (79 [22%]), Lower middle (292 [30%]), Upper middle (65 [31%]), High (24 [33%])
Gender Gap Index	Low (281 [33%]), High (179 [22%])

the decision threshold of the ML models, i.e., the probability cutoff above which a binary classifier labels an instance as positive. Thus, they can provide a more robust and stable assessment than metrics tied to a single threshold. In addition, AUC and MADD are complementary, as AUC deals with the likelihood of correct predictions across groups and MADD with the independence of the models' decisions toward group membership. Both metrics have been used in EDM fairness studies, e.g., [19, 23, 27, 29].

3. RESULTS

Table 3 reports on the evaluation of the ML models' fairness over the countries and characteristics. For the MADD, we indicate with a +/- sign whether the model's behaviour is in favour/biased (i.e., tends to give higher/lower probabilities of success in the MOOC) toward the target group. To formally compare these results, we apply a separate Friedman test for each unique combination of metric (group-level AUC and MADD), ML model (LR, SGB, and NB) and factor (countries or characteristics). Each test assesses differences in the metric across the levels of a single factor within one ML model, with repeated measures defined by the AUC/MADD values computed at each week and fold of cross-validation. To account for multiple comparisons, we apply the Benjamini–Hochberg method (BH) to adjust all p-values simultaneously across the full set of Friedman tests, making the correction stricter. We then examine significant main effects using pairwise Wilcoxon signed-rank tests with adjustment, and indicate in bold in Table 3 the values for which the tests show significant unfairness.

Sub-regions. Table 3 shows contrasting results. LR favors North Africa and is more biased against Middle Africa, while NB favors Western Africa and is more biased against Northern Africa. The Friedman tests show a significant main effect of sub-regions on AUC for RF ($p = 0.008, \eta^2 = 0.30$), and on MADD for LR, SGB and NB ($p = 0.0001, \eta^2 = 0.84$, $p = 0.0001, \eta^2 = 0.75$, $p = 0.001, \eta^2 = 0.67$, respectively). The post-hoc pairwise tests indicate that LR is significantly more biased toward Middle Africa on both metrics ($p < 0.03$). For SGB and NB, there is no significant difference in AUC, but the main effects and pairwise tests for MADD also show significantly more biases toward Middle Africa. These results provide evidence that the Middle Africa sub-region countries would experience some levels of unfairness with all models, especially LR, even though its passing rate is the highest (34%) among the three regions.

HDI. Table 3 shows that the AUC for High HDI countries is substantially higher than for the other groups with LR and SGB, but not NB. The Friedman tests only shows a significant main effect of HDI on AUC for LR ($p = 0.049, \eta^2 = 0.19$) and NB ($p = 0.038, \eta^2 = 0.20$), confirming the trends that LR is significantly less accurate for Low HDI and NB for high HDI. For all models, there is also a significant main effect in MADD ($p < 0.0001$, $\eta^2 > 0.66$ in all cases), consistently showing more biases for Low and Medium HDI groups, according to the post-hoc tests. These results show that LR exhibits clear biases for low HDI countries.

Literacy. The Friedman tests show no significant main effect of literacy groups on AUC, but significant main effects for all models on MADD ($p < 0.0001, \eta^2 > 0.51$). For all of these effects, the pairwise comparisons always show significant biases toward Low and Medium levels of Literacy, as compared to High (and surprisingly Very high for LR). These results show that literacy can capture ML unfairness in this dataset, but only in terms of MADD.

Quality of education. The Friedman tests show no main effects on AUC, but on MADD for LR and SGB ($p < 0.0001$, $\eta^2 > 0.52$). This suggests that the quality of education impacts to some extent the models' behaviors, but not their performance. The post-hoc tests for MADD indicate more biases toward the Low education groups ($p < 0.05$) across the models. More surprisingly, the same effect is found for the High education group (as compared to Lower middle and Upper middle), possibly due to its small size.

GDI. The Friedman tests reveal no main effect of GDI on

Table 3: Results per group and ML model. Bold means significantly more biased toward that group.

Factor	Values	LR		SGB		NB	
		AUC	MADD	AUC	MADD	AUC	MADD
Sub-regions	Northern Africa	0.82	1.03+	0.73	0.95+	0.69	0.28+

AUC and MADD, suggesting that no unfair treatments was observed in the models' outputs for this factor. This could stem from the fact that gender gaps are on the high side on the UN gender gap scales, meaning that this factor does not capture in sufficient details the nuances in gender gap across African countries, or conversely that all model can be trained fairly across GDI groups.

Countries. Table 3 shows that none of the African countries reach an AUC above 0.8, and that performances vary substantially across models. Friedman tests reveal a significant main effect of country on AUC for LR ($p = 0.006, \eta^2 = 0.25$), SGB ($p = 0.008, \eta^2 = 0.24$) and NB ($p = 0.002, \eta^2 = 0.29$). Post-hoc tests further indicate that LR is significantly less accurate for all African countries as compared to OECD ones, SGB for learners from Ivory Coast, and NB for learners from Cameroon. This shows that no model can perform reliably across African countries. There are also main effects of country on MADD for LR, SGB and NB. Post-hoc tests show that LR is more biased against all African countries as compared to OECD ones, SGB against all countries but Benin and DR Congo, and NB against Cameroon. Lastly, similarly to [13] when comparing African versus OECD countries (last two rows of Table 3), significant biases are observed for LR ($p = 0.002, \eta^2 = 0.19$) and SGB ($p = 0.039, \eta^2 = 0.11$), confirming that these models are more biased against Africa, even though African learners constitute the majority of the learners in this dataset.

4. DISCUSSION

Our results do show several patterns of unfairness in our ML predictors, thus answering our research question affirmatively. Three main trends of unfairness emerge in our results. First, we found evidence of biases toward learners from Middle Africa, a region that, to our knowledge, has received no prior attention in the ML fairness literature. We thus contribute to this work by providing strong evidence of biases in ML predictors trained on an international educational dataset for this part of Africa. Within Middle Africa, learners from Cameroon are exposed to biases in all models, especially NB. This calls for investigating further the possible reasons that could shape these learners' data in future work. In particular, Cameroon is characterized by strong multilingualism, severe infrastructural deficiencies in rural schools, and high dropout rates in primary and secondary education among girls and students from lower-income households [20]. Second, we uncovered biases against Western Africa, at least with LR and SGB. In related work on AI fairness in education, solely one study [6] looked at Nigerian learners (in Western Africa), without finding evidence of unfairness, possibly due to their small number of Nigerian data points. Within this region of Africa, we found in particular that learners from Burkina Faso, Senegal and Ivory Coast are exposed to varied levels of biases in the ML models, further reinforcing the per-African country analysis we propose in this paper. In a recent institutional report on deploying a MOOC at scale in Western Africa, educators from these countries reported specific issues that could explain different usage patterns of MOOCs resources [25].

Specifically, educators reported Internet connectivity issues leading to student dropouts in Burkina Faso; a clear lack of experience with remote learning in Ivory Coast; and the need for offline access to the MOOC in Senegal to enable participation for all learners. For Ivory Coast, we also found very low levels of interaction across the board, further showing that students from this country may have struggled with the MOOC's activities, which could have in turn make it more difficult for ML models to learn from these data. Third, we also found evidence of unfairness that appears to be matching existing struggles, namely countries with low HDI and low levels of adult literacy. To our knowledge, no prior studies have uncovered these trends, which, worth noticing, are not explained by sample size, since many biases affect large groups (e.g., Low HDI, Middle Africa). Overall, our findings highlight the need to broaden fairness research in ML to more diverse contexts, including replicating existing fairness studies in African settings.

Furthermore, as for the ML models, we found that LR generates substantial unfairness towards several groups, and in general is more favourable to OECD learners, which is consistent with the findings in [13] that LR is the most accurate but the most biased model. While this previous work also found that NB is the fairest model, we actually found that NB can be biased as well (e.g., toward Cameroon), showing that examining in depth unfairness is crucial to actually deploy an ML model. This confirms that different models trained on the same data can generate their own algorithmic biases.

Overall, the absence of correlation between the observed unfairness and subgroup pass rates, proportional representation, or absolute numbers of successful learners suggests that the sources of bias in our setting differ from typical representational and measurement biases, typically identified in Western educational contexts [4]. This observation complements the regional patterns discussed above and supports the hypothesis that commonly used modelling features, largely designed around assumptions and behavioural norms characteristic of Western learning environments, may not transfer well to African contexts. In particular, prior work has shown that while infrastructural constraints constitute a major barrier to MOOC adoption (often exceeding challenges related to self-discipline [9]), course contextualization, including the extent to which content reflects learners' lived realities, also plays a critical role in shaping engagement [5]. Alongside these factors, variations in digital literacy, constrained access to reliable infrastructure, and educational trajectories may shape learner behaviours in ways that are not adequately captured by current feature representations. As a result, existing modelling approaches may fail to encode meaningful indicators of learning and engagement, thereby contributing to systematic disparities in predictions. These findings highlight the need for context-sensitive feature design and fairness interventions explicitly accounting for linguistic, cultural, and infrastructural differences.

In addition to potential biases introduced by the ML models, the diversity of learning contexts and modalities for accessing the MOOC in African countries likely contributed to greater feature heterogeneity, which in turn affected model training. In the GDP-MOOC dataset, for instance, African learners interacted significantly less with videos (fewer videos played, and fewer actions such as pausing, seeking, or enabling transcripts) than OECD learners, according to a t-test with amount of video interaction as the dependent measure ($p < .05$). Within African subgroups, learners from the DR Congo showed the lowest levels of video interaction. These findings are consistent with prior work (see Introduction) emphasizing diverse modalities and challenges for accessing remote courses in Africa (e.g., mobile learning, access through digital open spaces), which may help explain some of the patterns observed here.

5. CONCLUSION

In this work, we explored the biases in ML predictors of MOOC completion, focusing on African learners, by leveraging the publicly available GDP-MOOC dataset, which includes logged events, outcomes, and learners' countries, with about half of them being African. To the best of our knowledge, our study is the first that focuses on eliciting complex patterns of unfairness within Africa in educational data.

Overall, our findings show diverse forms of unfairness that vary by ML model, highlighting the importance of investigating ML unfairness for subgroups of African learners. As these findings show no association with subgroup pass rates, proportional representation, or absolute numbers of successful learners, they suggest that the observed biases cannot be attributed solely to representation effects.

These findings provide strong evidence for the need to control for the fairness of ML predictors in education before deploying them in Africa, and provide insights about the specific groups needing more attention. However, due to the GDP-MOOC being in French, most of the African students came from countries with a sizable French-speaking population, typically Western, Middle, and Northern Africa, and future work should consider other parts of Africa and multilingual MOOCs. Another limitation is that we focused on one offering of a single MOOC, hence future work should aim at replicating the results over a larger and more balanced pool of MOOC learners. Lastly, while we provide possible reasons for the observed biases in the ML models, including structural and economical challenges documented in African studies about MOOCs, future work is still needed to link algorithmic unfairness with actual underlying causes.

With the rise of ML-driven tools in education, it is crucial to carefully consider their robustness for African learners, a continent with millions of learners who have received little attention so far in existing ML fairness studies in education. If we are to fulfill the promise that knowledge can reach a wider audience, we must pay close attention to cultural diversity at every stage of the educational and ML pipeline.

ABSTRACT

This study examined how self-regulated learning (SRL) processes differed between high- (n = 54) and low-performing (n = 57) writers during a 30-minute learning task. Adapting Fan et al.'s (2022) trace-based SRL protocol, we mapped 124,398 web log events onto eight SRL processes and further distinguished progress monitoring (timer/checklist checking) from comprehension monitoring (self-generated questioning). Group differences were tested using Mann–Whitney U tests with Benjamini–Hochberg correction across 5-minute windows, and monitoring–control coupling was examined through first-order Markov transitions. The groups did not differ in overall metacognitive frequency, but the low-performing group showed higher metacognitive activity at 20–25 min, mainly driven by comprehension-monitoring events that fed into quiz-response loops rather than strategic adaptation. In contrast, the high-performing group transitioned from Elaboration to Organisation earlier in the task. Although effect sizes were small to small-to-medium and several findings were marginal after correction, the results suggest that the effectiveness of monitoring–control coupling, rather than monitoring frequency alone, may distinguish writing performers.

Keywords

self-regulated learning, process mining, metacognitive monitoring, trace data, educational data mining

INTRODUCTION

Self-regulated learning (SRL) is a dynamic process in which learners actively set goals, select strategies, and monitor their progress toward desired outcomes [14, 15]. In technology-enhanced learning environments, SRL processes can be traced through timestamped log data that record learner interactions [2, 13]. Recent advances have enabled researchers to detect theoretically meaningful SRL processes from trace data using process mining techniques [4, 11].

A central yet under-investigated question is how the temporal deployment of metacognitive processes relates to learning outcomes. Prior studies have shown that self-regulated learners outperform less-regulated peers [1] , but most analyses treat metacognition as a unitary construct, without distinguishing between functionally different types of monitoring. This is problematic because monitoring frequency alone may not indicate effective self-regulation; what matters is whether monitoring triggers appropriate control actions [9, 14]. We restrict our scope to this monitoring–control coupling question in a single writing task, and do not make broader claims about motivational orientations such as mastery- versus performance-approach goals.

We address this gap by (a) adapting Fan et al.'s (2022) trace-based SRL measurement protocol, grounded in Bannert's (2007) framework, to a writing task context; (b) extending their process library by distinguishing *progress monitoring* from *comprehension monitoring*; and (c) examining monitoring–control coupling between groups using Markov transition analysis. Three research questions guide this study:

RQ1. How do cognitive and metacognitive SRL processes differ in temporal deployment between high and low writing performers?

RQ2. Does the temporal concentration of Organisation and Elaboration processes differ between groups across 5-minute time windows?

RQ3. Do progress monitoring and comprehension monitoring differ between groups in temporal distribution and downstream transitions?

METHOD

Participants and Task

111 sixth-grade elementary-school students (age 11) participated in a 30-minute web-based learning task that involved planning, video watching with embedded questions, and essay writing. Participants were recruited through promotional postings in nationwide online parent communities, and parental consent was obtained before any data were collected. Based on writing quality ratings, participants were classified into a high-performing group (n = 54) and a low-performing group (n = 57). A total of 124,398 timestamped events across 11 activity types were recorded. The study was reviewed and approved by the institutional review board of the Seoul National University (IRB No. 2507/001-014); both parental written informed consent and child assent were obtained prior to data collection, and log data were de-identified before analysis.

SRL Process Coding

We adapted the trace-based measurement protocol of Fan et al. (2022), which operationalises Bannert's (2007) theoretical

Hyeeun Kim, Minju Kang, Jeongyun Han, and Young Hoan Cho. Cognitive and Metacognitive Process Differences in High and Low Writing Performers: A Trace-Based SRL Analysis of Web Log Data. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) Proceedings of the 19th International Conference on Educational Data Mining, Seoul, Republic of Korea, June, 2026, pp. 611–615. International Educational Data Mining Society (2026).

framework of metacognition and cognition in hypermedia learning. The protocol maps raw trace data to learning actions (action library) and then to SRL processes (process library) through theoretically grounded sequence rules. Because the platform actions logged in our writing environment differ from the multi-channel hypermedia actions in Fan et al.'s original study, we re-constructed the action library to fit our 11 platform-logged actions and then mapped each action to the closest SRL process in Bannert's (2007) taxonomy; where the process requires temporal ordering, the mapping was applied to a two-step action sequence rather than to a single action. The resulting process library (Table 1) maps the 11 actions to eight SRL processes: five metacognitive (Orientation, Planning, Progress Monitoring, Comprehension Monitoring, Evaluation) and three cognitive (First-reading, Elaboration, Organisation). All mapping decisions were independently reviewed by the authors against Bannert's (2007) definitions before the process counts were computed.

Building on Fan et al.'s trace-based SRL framework, we retained Monitoring (MC.M) as a higher-order category but differentiated it into two theoretically meaningful subtypes. This refinement was based on the referent of monitoring rather than on surface action types alone. Progress Monitoring (MC.M_prog), comprising CHECK_TIMER, USE_CHECKLIST, and VIDEO → CHECKLIST, reflects learners′ monitoring of task progress, time, and procedural requirements, which is consistent with Zimmerman′s (2000) account of self-monitoring during performance. In contrast, Comprehension Monitoring (MC.M_comp), comprising QUESTION_VIDEO, captures learners' voluntary generation of questions about video content and can be interpreted as monitoring one's internal understanding. This interpretation aligns with reading and metacomprehension research, where self-questioning is viewed as an indicator of recognizing uncertainty or a comprehension gap [6, 10].

While Fan et al. (2022) treated monitoring-related traces as a single category, distinguishing MC.M_prog from MC.M_comp allows us to examine whether monitoring has different regulatory value depending on what learners monitor: task progress or internal understanding. This distinction is further grounded in Nelson and Narens's (1990) monitoring-control framework and the COPES model [5], which suggest that monitoring contributes to regulation when the information being monitored informs subsequent adaptive control.

Statistical Approach

Following Fan et al. (2022), who noted that SRL process distributions are typically non-normal and zero-inflated, all group comparisons used Mann–Whitney U tests. We retain this rank-based test as our primary inferential procedure for two reasons. First, the U statistic compares the full rank ordering of observations and tests stochastic dominance, not equality of medians; it therefore remains a valid group comparison even in cells where both group medians coincide at zero, since the rank-level difference between zero and non-zero observations is preserved in U. Second, the rank-biserial r derived from U ($r = 1 - 2U / n_1 n_2$) [8] is a standardised effect size that does not depend on the centre or scale of the distribution and is therefore directly interpretable for zero-inflated counts; $|r| \geq .20$ is treated as a small-to-medium effect, and Cohen's d is reported alongside r for interpretive reference. Across all 5- and 10-minute-window comparisons within each research question we applied a Benjamini–Hochberg false-discovery-rate correction (q = .05)[3], and both raw and corrected p values are reported; marginal effects ($.05 < p < .10$) are treated as exploratory and emphasised through effect sizes rather than p values. For temporal analysis, SRL process ratios were computed per 5-minute window, and first-order Markov transition probabilities were computed to examine monitoring–control coupling, providing an event-conditional view that is by construction free of the zero-inflation issue.

RESULTS

RQ1: Temporal Deployment of SRL Processes

Table 2 presents median SRL process durations across 10-minute windows. In the first 10 minutes, both groups primarily engaged in Planning and Elaboration, with the high group showing marginally greater Elaboration (Mdn: 247 vs. 183 s, $U = 1868$, $p = .052$, $r = –.21$). The critical divergence emerged at 10–20 min: the high group showed significantly greater Organisation (Mdn: 246 vs. 173 s, $U = 1953$, $p = .015$, $r = –.27$). In the 20–30 min window, the low group showed significantly greater Elaboration ($U = 1227$, $p = .006$, $r = +.20$) and marginally greater Progress Monitoring (Mdn: 13 vs. 5 s, $U = 1260$, $p = .099$, $r = +.18$), the latter likely reflecting anxiety-driven time checking when behind schedule.

Figure 1 shows dominant SRL process proportions across 5-minute windows. By 15–20 min, 81% of high performers had Organisation as their dominant process versus 61% of low performers, who maintained Elaboration longer (33% vs. 15% at 15–20 min).

Table 1. Process library mapping learning actions to SRL processes. Adapted from the measurement protocol of Fan et al. (2022), grounded in Bannert's (2007) theoretical framework. *MC.M_comp is our extension, not present in the original framework.

SRL Process	Learning Actions	Definition
MC.O Orientation	READ_INSTRUCTION NAV to INSTRUCTION	Orientation on task requirements and learning goals [2, 4].
MC.P Planning	PLAN_* ; NAV to PLAN	Planning by arranging activities and determining strategies[4].
MC.M_prog	CHECK_TIMER; USE_CHECKLIST;	Monitoring progress against time and task requirements. Progress monitoring of task completion and time management [15].
MC.M_comp*	QUESTION_VIDEO	Self-generated questioning indicating comprehension gap recognition. Monitoring without effective control when followed by repeated loops [6, 10, 14].
MC.E Evaluation	ANSWER_QUIZ	External evaluation of content understanding via platform-provided comprehension checks.
LC.F First-reading	WATCH_VIDEO	Initial information acquisition from instructional video.
HC.E Elaboration	USE_MEMO;	Connecting and recording content; note-taking during video as elaboration [7].

SRL Process	Learning Actions	Definition
	VIDEO → MEMO	
HC.O Organisation	WRITE_ESSAY; MEMO → ESSAY	Text production integrating learned information into coherent essay structure [4].

Note. Cells in which both groups display Mdn = 0.0 arise from zero-inflation, driven by the phase-structured task design (e.g., Planning concentrates in the opening minutes and Organisation in the closing minutes), by the voluntary low-base-rate nature of comprehension monitoring (QUESTION_VIDEO; see §4.2), and by two-step sequence rules in the process library that further restrict the non-zero rate. Mann–Whitney U is rank-based and remains valid in such cells: U and r summarise the rank-level difference between groups (driven by the proportion of non-zero observations) rather than the tied central tendency.

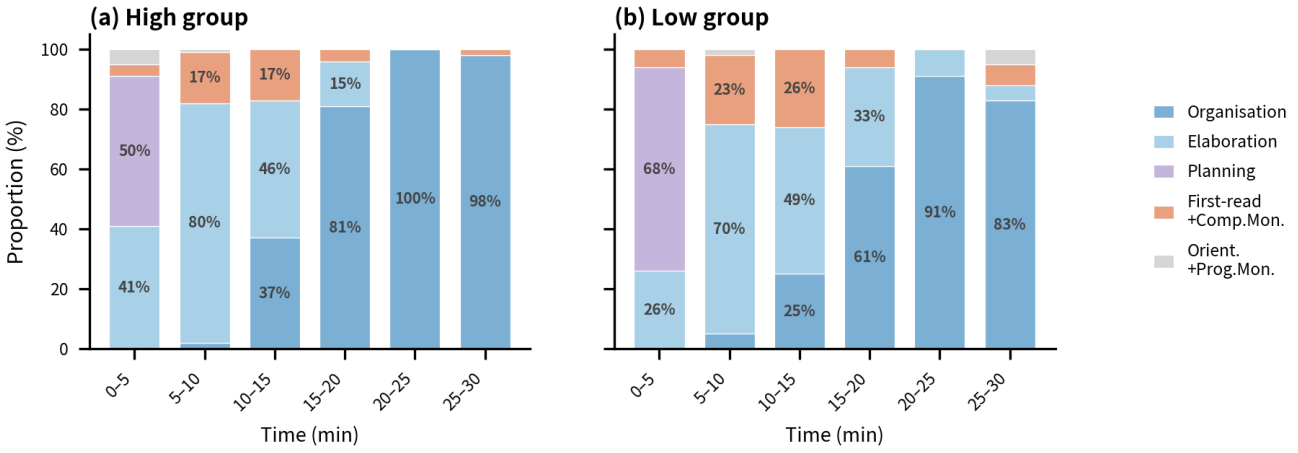

Figure 1. Dominant SRL process proportions across 5-min windows for high (a) and low (b) groups.

RQ2: Temporal Concentration

Organisation concentration (Figure 2a) showed a marginally significant difference at 15–20 min ($U = 1868$, $p = .052$, $r = –.21$). Elaboration (Figure 2b) showed a crossover: the high group had marginally higher Elaboration at 0–5 min ($U = 1825$, $p = .085$, $r = –.19$) but significantly lower Elaboration at 20–25 min ($U = 1127$, $p = .015$, $r = +.18$) and 25–30 min ($U = 720$, $p = .014$, $r = +.14$), indicating earlier completion of the Elaboration-to-Organisation phase transition.

RQ3: Monitoring and Control Coupling

Total metacognition ratio (Figure 2d) was significantly higher for the low group at 20–25 min ($U = 1015$, $p = .020$, $r = +.26$). Comprehension Monitoring (Figure 2c) showed elevated trends for the low group, particularly at 10–15 min (Mdn: 0% for both groups, but the low group's distribution had a substantially heavier right tail). Progress Monitoring was marginally higher for the low group at 20–25 min ($U = 1086$, $p = .061$, $r = +.21$).

Post-monitoring transition analysis (Figure 3) revealed differential monitoring–control coupling. After Progress Monitoring, both groups transitioned primarily to Organisation and Navigation, with similar patterns. However, after Comprehension Monitoring, the low group transitioned to Evaluation (quiz loop) at a higher rate (35.5% vs. 27.3%), while the high group showed higher Navigation probability (24.2% vs. 15.1%), suggesting strategic disengagement from unproductive comprehension checking.

The transition WRITE_PLAN → NAVIGATE was significantly more frequent in the low group (Mdn: 1 vs. 0, $U = 1155$, $p = .010$, $r = +.25$), suggesting greater post-planning disorientation. Conversely, WRITE_ESSAY → NAVIGATE was significantly more frequent in the high group ($U = 1869$, $p = .037$, $r = –.21$),

reflecting more active navigation during writing.

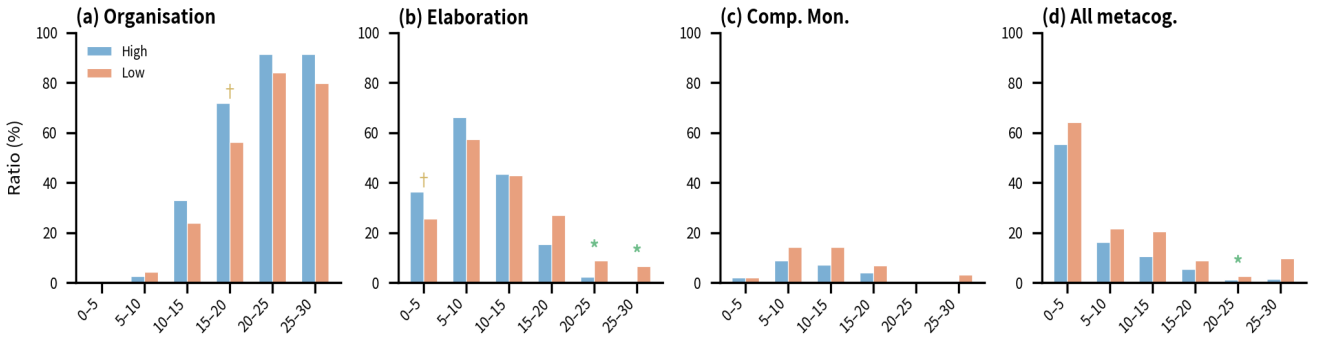

Figure 2. SRL process concentration across 5-min windows. (a) Organisation. (b) Elaboration. (c) Comprehension Monitoring. (d) Total metacognition. * $p < .05$, † $p < .10$.

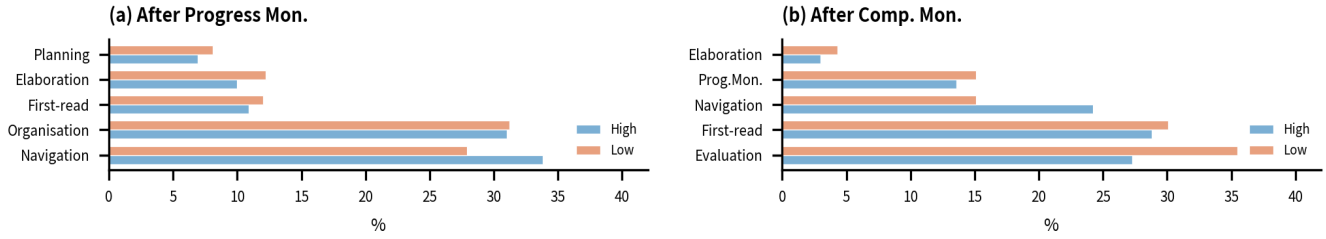

Figure 3. Post-monitoring transition probabilities. (a) After Progress Monitoring: similar patterns. (b) After Comprehension Monitoring: low group → Evaluation (quiz loop); high group → Navigation (strategic redirection).

DISCUSSION

Applying a trace-based SRL measurement protocol adapted from Fan et al. (2022) to web log data from a single writing task, this study finds that, within the bounds of this task, writing performance differences are associated with the functional effectiveness of metacognitive processes rather than with their raw frequency.

Monitoring without effective control. Our most theoretically significant finding is the differential monitoring–control coupling between groups. The low group engaged in more Comprehension Monitoring (self-questioning during video), yet this monitoring disproportionately led to Evaluation (quiz-answering) rather than strategic redirection. This exemplifies what Winne and Hadwin (1998) describe as a breakdown in the monitoring–control loop: learners detect a comprehension gap but respond passively rather than adapting strategy [14]. That the total metacognition ratio was significantly *higher* for the low group at 20–25 min (p = .020) directly challenges the common assumption that more metacognition implies better self-regulation.

The Elaboration-to-Organisation phase transition. The Elaboration crossover pattern, in which Elaboration is higher early and lower late for the high group, demonstrates a phase transition aligned with Kellogg's (1996) writing model [7]. The high group completes this transition earlier not because they elaborate less overall but because their early elaboration is more intensive, enabling a faster transition to text production.

Progress Monitoring as a lagging indicator. The marginally higher Progress Monitoring in the low group at 20–25 min likely represents reactive time checking when behind schedule, rather than proactive self-regulation. This cautions against equating monitoring frequency with quality, consistent with Schraw's (1998) distinction between monitoring accuracy and frequency [12].

Methodological Contributions

This study extends the trace-based SRL measurement protocol of Fan et al. (2022) in two ways [4]. First, our decomposition of Monitoring into productive and comprehension subtypes reveals functionally distinct processes with opposing relationships to performance, a distinction invisible when Monitoring is treated as a unitary category. Second, the post-monitoring transition analysis operationalises the monitoring–control coupling concept from Winne and Hadwin's (1998) COPES model in a data-driven manner, providing an empirical method for assessing whether monitoring leads to effective strategy adaptation [14].

Limitations

Several limitations qualify these findings. First, causal direction cannot be established from cross-sectional trace data; the observed Elaboration-to-Organisation timing differences may function either as antecedents or consequences of writing quality. Second, WRITE_ESSAY frequency is partly confounded with text quantity, creating potential circularity with the quality-based grouping. Future work should use independent baseline writing measures and consider sequence balancing to reduce the influence of overall activity volume on SRL process counts. Third, several SRL-process duration variables were zero-inflated, partly due to the phase-structured task design, the low-base-rate nature of QUESTION_VIDEO, and the restrictive two-step sequence rules. Although the Mann–Whitney U test can capture rank-level group differences under these conditions, medians are less informative when many observations are zero. Future studies could use hurdle or zero-inflated models to distinguish the presence of a process from its duration conditional on occurrence. Fourth, some effects were marginal and small to small-to-medium in size; even with Benjamini–Hochberg correction, the findings should be interpreted as preliminary and require replication with larger samples. Fifth,

the process library relied only on single-action and two-step sequence detection. As Fan et al. (2022) showed, richer multi-channel data such as eye-tracking or think-aloud protocols can improve SRL-process detection granularity, and our mapping may under-capture higher-order regulatory episodes. Finally, because the data came from a single writing task and learner population, cross-task and cross-domain validation is needed before the proposed monitoring decomposition can be treated as a general SRL measurement contribution.

ABSTRACT

Large language models (LLMs) show promise as educational aids but often lack alignment with specific course materials. We investigate Retrieval-Augmented Generation (RAG) and GraphRAG for page-level question answering on an undergraduate mathematics textbook. Using a curated dataset of 477 question-answer pairs, each tied to a specific textbook page, we compare five embedding-based RAG models, a BM25 baseline, and GraphRAG across two metrics: retrieval accuracy (whether the correct page is retrieved) and answer quality (F1 score). Our results show that embedding-based RAG outperforms GraphRAG for page-level retrieval, with `voyage-3-large` achieving 99.4% accuracy at top-10 (bootstrap 95% CI for top-1: [.644, .728]). BM25 proves a strong baseline, outperforming several embedding models. Error analysis reveals that 63.3% of top-1 failures retrieve same-chapter content, suggesting pedagogical relevance even in failure cases. GraphRAG retrieves excessive context (∼47K tokens vs. ∼3.7K for RAG), reducing generation quality. We further replicate key experiments using an open-source local LLM (Qwen3.5-35B-A3B), finding that RAG benefits are proportionally larger for weaker models (+39% vs. +16% relative F1 improvement), an important result for cost-sensitive educational deployments. These findings inform the design of AI tutoring systems that reference specific textbook pages.

Keywords

Retrieval-Augmented Generation, GraphRAG, Mathematics Education, Question Answering, AI Tutoring

1. INTRODUCTION

During self-paced study, students frequently need to locate specific textbook pages, for example to revisit a definition they have forgotten, review a proof they found confusing, or find the relevant section for a homework problem. Large language models (LLMs) have shown notable capabilities in domains such as mathematics [1, 27], yet they often lack alignment with specific course content and may produce hallucinated sources [15, 4]. For instance, prior work has shown that LLMs tend to overestimate question quality without precise course alignment [21] and struggle with complex mathematical problems in digital learning games [24]. Retrieval-Augmented Generation (RAG) addresses these limitations by combining information retrieval with LLM generation, grounding responses in domain-specific documents [10, 31]. Recent work has demonstrated RAG's effectiveness in building LLM-based tutors across various educational settings [12, 20, 9, 16, 33, 18], though challenges remain around groundedness, user trust, and retrieval transparency [6, 17].

GraphRAG [8] extends standard RAG by constructing knowledge graphs from the corpus, capturing entity relationships and enabling more structured retrieval [5]. While research has shown GraphRAG can enhance question-answering performance in some settings [13, 19], it may also introduce excessive or irrelevant content in fine-grained retrieval tasks [28, 32]. In educational contexts, it is critical that AI tutors not only provide correct answers but also precisely reference the pages students need [7, 29], enabling verification and deeper learning [6, 17].

We address the following research question: *"To what extent can an AI-based retrieval system identify the correct textbook page for a question derived from that specific page?"* We compare embedding-based RAG, a BM25 sparse-retrieval baseline, and GraphRAG on a custom dataset of 477 question-answer pairs from an undergraduate mathematics textbook [23], evaluating retrieval accuracy, generated answer quality (F1 score), and error patterns. Our contributions include: (1) a systematic comparison of seven retrieval approaches (five embedding models, BM25, and GraphRAG) for page-level educational QA; (2) an error analysis showing that most retrieval failures surface pedagogically relevant content from nearby pages; (3) evidence that BM25 remains a competitive baseline, outperforming several neural embedding models; and (4) practical recommendations for deploying RAG-based AI tutors.

2. METHODS

2.1 Dataset

Eason Chen, Chuangji Li, Shizhuo Li, Zimo Xiao, Jionghao Lin, and Ken Koedinger. Comparing RAG and GraphRAG for Page-Level Retrieval Question Answering on a Math Textbook. We used the undergraduate textbook *An Infinite Descent into Pure Mathematics* [23] as our corpus. The textbook contains 628 pages covering topics in pure mathematics. Each page was converted from PDF to LaTeX-based Markdown via GPT Vision OCR [26, 11]. We generated one question-answer pair per page (628 total) using `gpt-4o-mini`, prompting it to produce questions representative of what students might ask during self-study, for example requesting clarification of a definition, asking how to apply a theorem, or seeking the proof of a result. Two authors, who completed undergraduate coursework using this textbook, then manually reviewed all pairs, filtering out front/back matter (reducing to 528) and eliminating poorly formed or educationally irrelevant questions, yielding a final set of 477 curated pairs that reflect the types of page-specific queries students encounter when studying mathematics independently. Each pair is labeled with its source page number, enabling precise evaluation of page-level retrieval.

2.2 RAG Pipeline

Figure 1 illustrates our pipeline, consisting of three stages: (1) *Indexing*, where pages are embedded as vectors (RAG), indexed as term-frequency vectors (BM25), or encoded as relational entities (GraphRAG); (2) *Retrieval*, where the top-k most relevant pages or entities are identified; and (3) *Generation*, where the query, prompt, and retrieved content are fed to an LLM for answer generation.

2.3 Models and Baselines

We selected five embedding models from the December 2024 Massive Text Embedding Benchmark (MTEB) leaderboard [22, 14]: `voyage-3-large` and `nv-embed-v2` were chosen for their high rankings; `gte-large` is commonly used as a fine-tuning base; `text-embedding-3-large` was included for its widespread adoption; and `multilingual-e5` for its multilingual capabilities. We also include a **BM25** sparse-retrieval baseline using Okapi BM25 with default parameters, to contextualize neural embedding gains against a classical term-matching approach that requires no training or fine-tuning. For each model, we tested retrieval at $k \in \{1, 3, 5, 10\}$.

For GraphRAG [8], we adapted the framework to expose `document_ids` for each entity and text unit, enabling page-level traceability. Specifically, we modified various GraphRAG components to store and output fields such as `document_ids` and `entity_ids`, allowing our system to link each retrieved item back to a corresponding page number. We tested GraphRAG with both `gpt-4o-mini` and `o3-mini` as the underlying LLM. Note that since GraphRAG retrieves entire entities and community summaries rather than ranked pages, we cannot directly control the number of pages returned; accuracy is evaluated based on whether the correct page's entities appear in the retrieved data.

2.4 Evaluation Metrics

We evaluate with two metrics: (1) **Retrieval Accuracy**, whether the correct source page appears in the retrieved set, averaged across all 477 queries; and (2) **F1 Score**, word-overlap F1 between the generated answer (produced by `gpt-4o-mini` given retrieved context) and the ground-truth answer. The F1 score captures the balance between precision (fraction of generated words appearing in the reference) and recall (fraction of reference words appearing in the generated output). We report bootstrap 95% confidence intervals (10,000 resamples) for key comparisons to assess statistical significance. We also conducted an error analysis of retrieval failures, categorizing top-1 misses by page distance and chapter membership to understand whether failures are near-misses or far-misses. Additionally, we tested LLM-based re-ranking of retrieved pages using `gpt-4o-mini`, where the model reorders retrieved pages by estimated relevance to the query.

Table 1: Retrieval accuracy for embedding-based RAG models, BM25, and GraphRAG. GraphRAG retrieves entities rather than ranked pages, so only overall accuracy is reported.

Model	Top-1	Top-3	Top-5	Top-10
voyage-3-large	**.686**	**.910**	**.958**	**.994**
nvidia/nv-embed-v2	.585	.843	.912	.964
BM25	.579	.780	.855	.929
OpenAI emb-3-large	.549	.811	.893	.933
gte-large	.461	.711	.799	.881
multilingual-e5	.457	.702	.795	.870
GraphRAG (o3-mini)		.914		
GraphRAG (4o-mini)		.845		

3. RESULTS

3.1 Retrieval Accuracy

Table 1 presents retrieval accuracy results. Among all models, `voyage-3-large` achieves the highest accuracy across all top-k settings, reaching 99.4% at top-10. Bootstrap 95% CIs for top-1 accuracy confirm that `voyage-3-large` ([.644, .728]) significantly outperforms `nv-embed-v2` ([.541, .629]), as these intervals do not overlap at top-1 or top-3.

BM25 proves a strong sparse-retrieval baseline, achieving top-1 accuracy of .579, outperforming both `gte-large` (.461) and `multilingual-e5` (.457) at all k values despite using no learned representations. This highlights the importance of including classical baselines in retrieval evaluations. Despite strong MTEB leaderboard rankings, `multilingual-e5` underperformed on this domain-specific task, underscoring that benchmark performance does not always transfer to specialized mathematical domains.

GraphRAG achieves 84.5% with `gpt-4o-mini` and 91.4% with `o3-mini`. All five embedding models surpass GraphRAG's accuracy at top-5 or above. The gap between the two GraphRAG configurations suggests that the underlying LLM quality substantially affects graph-based retrieval performance.

3.2 Generated Answer Quality

Table 2 shows F1 scores for answer generation. The no-retrieval baseline (`gpt-4o-mini` alone) achieves 0.475. All RAG configurations improve upon this, with F1 scores ranging from 0.514 to 0.552, confirming that retrieval grounding consistently benefits domain-specific QA. GraphRAG achieves F1 of $\sim$0.524, comparable to but slightly below the best embedding-based results.

Interestingly, `nv-embed-v2` achieves the highest top-1 F1

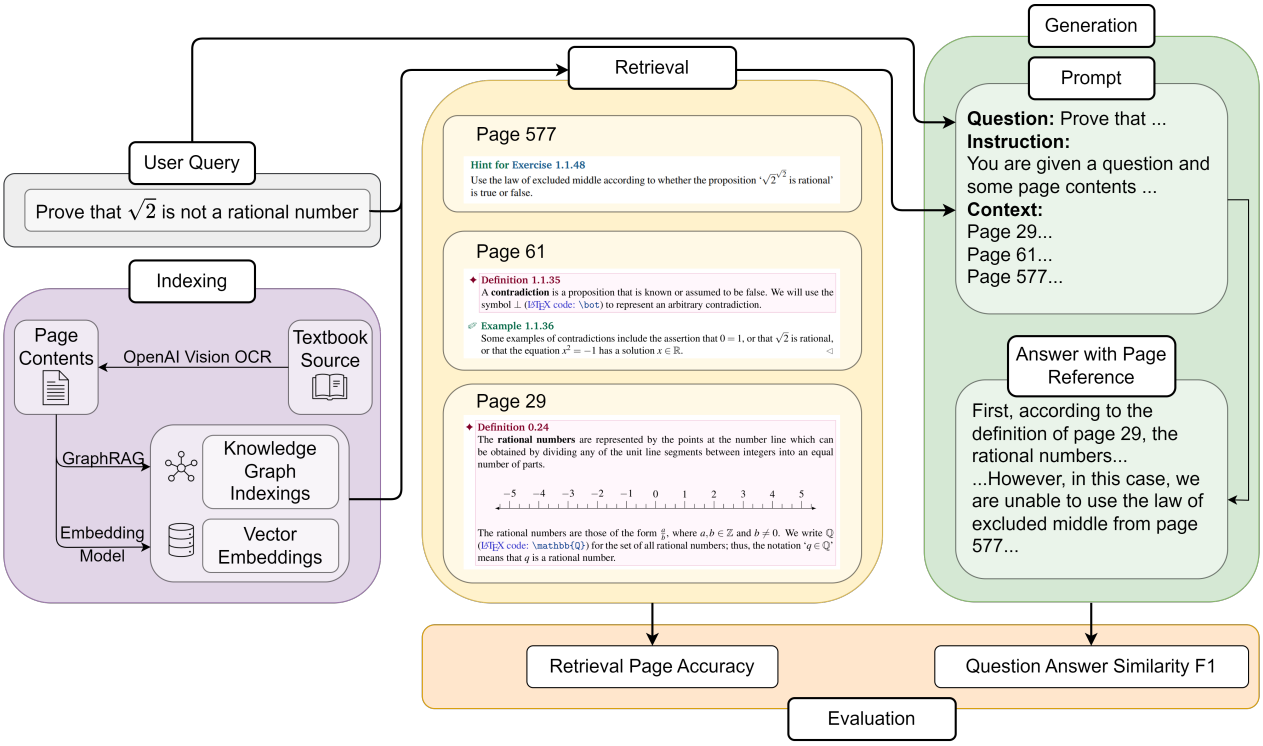

Figure 1: Our RAG pipeline: Indexing, Retrieval, and Generation stages with two evaluation metrics.

Table 2: F1 scores for generated answers. Baseline is `gpt-4o-mini` without retrieval (F1 = 0.475).

Model	Top-1	Top-3	Top-5	Top-10
voyage-3-large	.523	.543	.544	.547
nvidia/nv-embed-v2	**.537**	.542	.541	.539
OpenAI emb-3-large	.531	.549	.533	.543
gte-large	.526	.533	.550	**.552**
multilingual-e5	.514	.534	.541	.535
GraphRAG (o3-mini)		.524		
GraphRAG (4o-mini)		.525		
No retrieval		.475		

(.537) despite lower retrieval accuracy than `voyage-3-large`, suggesting retrieval accuracy and generation quality do not always correlate, because near-miss retrievals still provide useful context. Increasing k generally does not improve F1, as additional pages introduce noise. GraphRAG's ∼47K tokens of context per query (vs. ∼3.7K for top-5 RAG) overwhelms the generator, suggesting that *retrieval precision* matters more than *recall* for generation quality.

3.3 Re-Ranking

LLM-based re-ranking with `gpt-4o-mini` yielded mixed results. Re-ranking top-5 pages degraded `voyage-3-large`'s top-1 accuracy from .686 to .593, while re-ranking top-10 caused further degradation across all models. Critically, we observed hallucinated page numbers in re-ranking outputs: the LLM occasionally referenced pages not in the retrieved set. These findings suggest that LLM-based re-ranking is unreliable for page-level retrieval, particularly with larger candidate sets.

3.4 Error Analysis

We examined the 150 top-1 failures from `voyage-3-large`, categorizing each by page distance and chapter membership. Of these, 46.0% retrieved an adjacent page (distance ≤ 2), 17.3% retrieved a same-chapter but non-adjacent page, and 35.3% were far misses (different chapter). Overall, 63.3% of failures retrieved same-chapter content, with a median page distance of just 3 pages. This suggests that even "incorrect" retrievals often surface pedagogically relevant material. For example, a student asking about a proof may be directed to the adjacent page containing the theorem statement, content that is still valuable for building understanding and that an instructor might recommend reviewing first. The high proportion of near-misses reflects the textbook's pedagogical structure, where definitions, theorems, and proofs are deliberately organized across consecutive pages to support incremental learning. The 35.3% far misses, where shared terminology across chapters causes cross-topic confusion, represent the genuinely problematic failures that could misdirect students.

3.5 Open-Source LLM Replication

To assess whether our findings generalize beyond commercial APIs, we replicated key experiments using Qwen3.5-35B-A3B [30], an open-source 36B Mixture-of-Experts model running locally on 2× NVIDIA TITAN RTX GPUs with Q4_K_M quantization via Ollama. For retrieval, we tested `nomic-embed-text` [25], an open-source embedding model, also served locally.

Table 3: F1 scores: commercial API vs. open-source local LLM.

Configuration	gpt-4o-mini	Qwen3.5-35B
No retrieval	0.475	0.276
Best RAG + generation	0.552	0.384
Relative improvement	+16%	+39%

Table 3 compares generation quality (F1) between the commercial `gpt-4o-mini` and the local Qwen3.5 setup. Without retrieval, Qwen3.5 achieves substantially lower F1 (0.276 vs. 0.475). However, adding RAG with `nomic-embed-text` retrieval improves Qwen3.5's F1 to 0.384, a **39% relative improvement**, compared to only 16% for `gpt-4o-mini` with its best embedding model. This suggests that *weaker models benefit disproportionately from retrieval grounding*, as they rely more heavily on external context to compensate for limited parametric knowledge.

For retrieval accuracy, `nomic-embed-text` achieved top-1 accuracy of 45.1%, top-3 of 71.3%, and top-10 of 88.7%, below the best commercial embeddings but still serviceable. Notably, BM25 (61.2% top-1) again outperforms this neural embedding model, reinforcing BM25's strength as a zero-cost baseline.

We also attempted GraphRAG v3.0.6 indexing with Qwen3.5, successfully extracting 4,528 entities, 10,828 relationships, and 1,107 communities. However, query-time generation failed due to incompatibilities between GraphRAG's OpenAI-compatible API expectations and Qwen3.5's thinking-mode architecture. This demonstrates that while local LLM indexing for GraphRAG is feasible, end-to-end integration with open-source models remains challenging.

4. DISCUSSION AND CONCLUSION

Our findings yield several key insights for designing RAG-based educational AI systems.

RAG consistently improves over baseline LLMs. All RAG configurations produced higher F1 scores than the no-retrieval baseline (0.475 vs. 0.514 to 0.552), confirming that grounding LLM responses in textbook content improves answer quality for domain-specific question answering. This improvement is meaningful in educational settings where students benefit from answers grounded in their assigned course materials rather than the LLM's general pre-training data, which may contain incorrect or outdated mathematical content [3, 2].

Embedding-based RAG outperforms GraphRAG for page-level retrieval. GraphRAG retrieves excessive context (∼47K tokens vs. ∼3.7K for top-5 RAG), leading to lower precision and comparable or lower F1 [28, 32]. This reflects a *task-method mismatch*: GraphRAG was designed for global summarization and multi-hop reasoning, not page-level lookup. For educational applications where students need a specific page reference, the simpler embedding-based approach is more appropriate. However, GraphRAG may excel at cross-concept questions (e.g., "How do induction and well-ordering relate across chapters?") where its entity-based structure could surface connections that page-level retrieval would miss.

BM25 is a competitive baseline. BM25 outperforms two of five embedding models at all k values, partly due to high lexical overlap (72% unigram) between questions and source pages. This underscores the importance of including classical baselines, as neural embeddings do not always yield proportional gains, particularly when questions and documents share substantial vocabulary.

Most retrieval failures are near-misses with pedagogical value. Our error analysis reveals that 63.3% of top-1 failures retrieve same-chapter content (median distance: 3 pages). From an educational perspective, this means a student directed to the "wrong" page is still reading closely related material in most cases, analogous to how a tutor might say "look at the previous page first" before addressing the specific question. The top-1 accuracy of 68.6% may appear insufficient, but the near-miss pattern means the system rarely sends students to entirely irrelevant content.

Re-ranking introduces more risk than benefit. LLM-based re-ranking degraded performance for top-performing retrievers and introduced hallucinated page references, suggesting general-purpose LLMs struggle to distinguish between mathematically similar pages. Deployments requiring re-ranking should explore fine-tuned cross-encoder models or constrained decoding.

Open-source LLMs are viable but benefit more from RAG. RAG provides proportionally larger gains for weaker models (+39% vs. +16% relative F1 improvement), suggesting that retrieval grounding partially compensates for reduced model capability. This is significant for educational settings where commercial API costs are prohibitive, and aligns with EDM 2026's "Across Borders" theme, because institutions can deploy useful textbook-grounded QA systems on local hardware rather than relying on commercial APIs. Our results show that a locally hosted open-source model combined with BM25 retrieval (requiring no GPU for the retrieval component) can deliver meaningful QA quality at near-zero marginal cost.

Practical recommendations. (1) Use top-5 RAG retrieval as default (accuracy .958, ∼3.7K tokens); (2) present top-3 candidate pages to students (accuracy >91%); (3) avoid LLM re-ranking due to hallucination risk; (4) consider adjacent-page windowing to capture theorem-proof pairs spanning page boundaries.

Limitations and Future Work. While questions were curated by course-familiar authors to reflect realistic student queries, their high lexical overlap with source pages (72% unigram) may inflate retrieval accuracy relative to more diverse student phrasings; future work should supplement with authentic questions from discussion forums or office hours. Word-overlap F1 is a weak proxy for math QA, as mathematically equivalent expressions can score poorly; LLM-as-judge or symbolic equivalence checking would better capture correctness. Extending to multiple STEM textbooks, investigating hybrid BM25+dense retrieval, and conducting classroom studies measuring whether page references improve comprehension and student trust are important next steps. Notably, `multilingual-e5`'s underperformance despite strong general benchmarks raises questions about deploying these systems for non-English textbooks, an important consideration for

educational equity across linguistic borders.

ABSTRACT

Establishing adaptation rules is a key step in designing effective adaptive systems and is traditionally carried out by domain experts. This paper presents a novel approach based on a constrained multimodal neural network (NN) to extract actionable adaptation rules from learner data. Unlike post-hoc explainability methods, the architecture is intrinsically interpretable through non-negative weight constraints, enabling stable and globally consistent identification of adaptation levers. The extracted patterns are validated using a decision tree and operationalized into concrete rules regulating feedback, NPC reactions, and emotional scaffolding in a serious game. An empirical evaluation comparing adaptive and non-adaptive versions shows improved learning outcomes (with marginal statistical significance, $p = 0.058$) and significantly enhanced emotional states conducive to learning ($p < 0.001$).

Keywords

Adaptation Rules, Socio-moral Reasoning, Neural Networks, Decision Tree, Game-Based Learning

1. INTRODUCTION

Adaptive game-based learning systems personalize learning by adapting to learners' cognitive, behavioral, and affective states [1]. Central to these systems are *adaptation rules* that govern feedback and pedagogical interventions, yet they are typically expert-defined, limiting scalability and responsiveness to multimodal data [14].

Prior work has explored adaptive mechanisms using knowledge tracing, Bayesian models, and deep learning [11, 6], but often focuses on task selection while overlooking affective and interactional dimensions critical for engagement in serious games [15]. In open-ended environments, adaptation must also regulate feedback, emotional engagement, and character interactions [20].

Neural networks (NNs) can model complex multimodal data but remain difficult to translate into actionable pedagogical rules [8, 4]. Existing rule extraction methods rely on post-hoc explanations or expert-driven design. In contrast, we propose a constrained multimodal NN that embeds interpretability through non-negative weights, enabling stable and globally consistent rule extraction.

This paper makes three contributions: (1) a constrained multimodal NN architecture with intrinsic interpretability; (2) a rule extraction pipeline combining weight analysis and decision tree validation; and (3) an empirical evaluation in a serious game context.

More broadly, we show that constraining neural architectures can transform them into interpretable rule generators, bridging data-driven modeling and actionable pedagogical decision-making.

2. LESDILEMMES: GAME CONTEXT

LesDilemmes [17, 16] is a serious game designed to assess and develop socio-moral reasoning in youths (ages 8–18). Players engage with dilemmas, justify decisions, and evaluate NPC responses spanning five reasoning levels from the So-Moral framework [3]: (1) Authoritarian, (2) Egocentric, (3) Interpersonal, (4) Societal, and (5) Evaluative. Intermediate levels (1.5–4.5) capture developmental transitions. These levels are modeled as developmental constructs independent of age, enabling joint analysis across participants.

The learner model integrates affective state, cognitive profile, and socio-moral reasoning. Game dynamics combine social feedback (e.g., "likes") with pedagogical rules governing NPC reactions and feedback.

Expert-defined rules regulate interactions. For instance, agreement with a higher-level NPC ($r_n > r_p$) triggers positive feedback, while learners below level 4 receive encouragement and scaffolding toward higher reasoning. These rules may co-occur, reflecting authentic pedagogical practice.

3. CONSTRAINED MULTIMODAL NEURAL NETWORK

3.1 Architecture

We use a multilayer perceptron (MLP) as a structured aggregation mechanism for multimodal learner data. All weights are constrained to be non-negative, ensuring intrinsic interpretability [5]. All inputs are normalized to $[0, 1]$.

Given a neuron with inputs x_1, x_2 and non-negative weights w_1, w_2:

$$y = f(w_1 \cdot x_1 + w_2 \cdot x_2 + b) \quad (1)$$

where f is ReLU. Under non-negativity, feature importance is directly reflected by weight magnitude ($w_1 > w_2 \Rightarrow x_1$ is more influential).

The model integrates three modalities (Fig. 1): (1) emotions (9 features), (2) NPC evaluations (5 binary features), and (3) gameplay context (reasoning level of the first NPC visited). The output layer uses Softmax to predict $[1, 0]$ (reasoning ≤ 3) or $[0, 1]$ (reasoning > 3). A dropout layer prevents overfitting given the limited dataset.

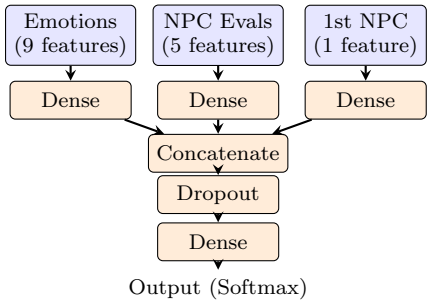

Figure 1: Constrained multimodal NN architecture for rule extraction.

3.2 Feature Importance Computation

To mitigate stochastic variability, 20 training runs are performed. Feature importance $A_{i,j}$ for input i predicting output j is computed using softmax normalization of penultimate-layer weights:

$$a_{i,j} = \frac{e^{w_{i,j}}}{\sum_{i=1}^{n} e^{w_{i,j}}} \quad (2)$$

$$A_{i,j} = \frac{\sum_k a_{i,j,k}}{\sum_k \sum_j a_{i,j,k}} \quad (3)$$

where k indexes training runs. Higher $A_{i,j}$ indicates greater influence on the prediction of output j.

This design transforms the neural network from a predictive black box into a structured aggregation mechanism whose weights directly encode interpretable relationships between learner features and outcomes. As a result, the model supports global rule extraction rather than local post-hoc explanations.

4. RULE EXTRACTION AND VALIDATION

4.1 Neural Network Analysis

Table 1 reports the penultimate-layer weights and averaged importance $A_{i,j}$ across 20 runs. *Emotions* consistently show the highest importance ($A_{i,1} = 0.475$, $A_{i,2} = 0.689$), outweighing NPC evaluations and first NPC visited.

The predictive performance of the model reached an average classification accuracy between 65% and 70% depending on the training run, which is consistent with the exploratory nature of the study and the limited dataset size. Importantly, the NN is not used as a final predictive model but as a mechanism for identifying stable explanatory patterns across modalities—which is why the final adaptation rules combine NN importance rankings with decision tree thresholds. This hybrid strategy compensates for the NN's inability to directly specify threshold values while leveraging its capacity to model nonlinear multimodal interactions.

Table 1: CMNN penultimate layer weights from 3 runs. $A_{i,j}$ averaged over 20 runs.

	Run 1		Run 2		Run 3		$A_{i,j}$	
Modality	[1,0]	[0,1]	[1,0]	[0,1]	[1,0]	[0,1]	[1,0]	[0,1]
Emotions	.007	.812	.000	.751	.925	.739	.475	.689
Eval NPCs	.066	.000	.323	.040	.043	.378	.367	.276
1st NPC visited	.067	.607	.742	.099	.116	.071	.158	.035

Table 2 details importance per emotion. **Arousal** is the most influential ($A_i = 0.234$), followed by sadness (0.165), surprise (0.155), and happiness (0.120). Table 3 shows that NPCs at levels 2 and 5 are most predictive ($A_i = 0.215$ and 0.273 respectively).

Table 2: Emotion branch weights and importance A_i (20 runs).

Emotion	Run 1	Run 2	Run 3	A_i
Neutral	.080	.093	.000	.001
Happy	.000	.475	.000	.120
Sad	.672	.013	.333	.165
Angry	.069	.702	.000	.090
Surprised	.000	.034	.583	.155
Scared	.138	.000	.041	.001
Disgusted	.000	.016	.001	.106
Valence	.346	.006	.045	.128
Arousal	.039	.404	.578	**.234**

Table 3: NPC evaluation weights and importance A_i (20 runs).

NPC Level	Run 1	Run 2	Run 3	A_i
Eval 1	.939	.186	.000	.198
Eval 2	.078	.755	.000	**.215**
Eval 3	.052	.000	.938	.167
Eval 4	.028	.588	.000	.147
Eval 5	.920	.369	.000	**.273**

4.2 Decision Tree Validation

A decision tree (Fig. 2) trained on the same dataset validates the NN findings and provides threshold values for operationalization. Key extracted rules:

- Low *arousal* $\Rightarrow$ higher probability of reasoning level > 3
- Agreement with NPC level 2 + low disgust $\Rightarrow$ reasoning level > 3
- No agreement with NPC level 2 + low surprise $\Rightarrow$ reasoning level < 3
- No agreement with NPC level 2 + agreement with NPC level 3 $\Rightarrow$ reasoning level > 3

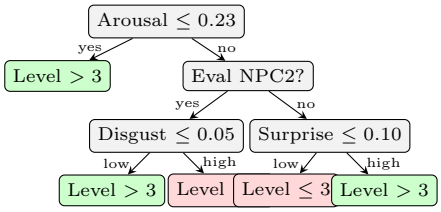

Figure 2: Simplified decision tree for socio-moral reasoning prediction.

These findings motivate concrete game adaptations: background music is changed according to arousal and valence, and players are required to visit all NPCs (including levels 2 and 5) rather than stopping after three.
While the decision tree is trained on the same dataset, it provides an independent, symbolic approximation of the learned relationships, enabling the identification of explicit thresholds and facilitating operational deployment. One advantage of using the NN is that, as the data grows, the model will still be able to highlight features that need to be observed and modified to improve the mastery of the knowledge, compared to the decision tree alone.

5. EMPIRICAL EVALUATION

5.1 Dataset and Protocol

29 youths (ages 8–18) played the non-adaptive version of *LesDilemmes* across 9 dilemmas, yielding 261 observations. Verbal justifications were transcribed via Google Speech-to-Text and analyzed with a data mining algorithm. Emotional data were collected via *Facereader* (7 basic emotions + valence + arousal). An adaptive version incorporating the extracted rules was subsequently developed and evaluated against the baseline.

5.2 Learning Outcomes

Table 4 reports paired t-test results. Players showed significant improvement from pre-test (mean 1.70) to in-game performance (2.30, $p = 0.029$) and post-test (2.49, $p < 0.001$). The non-significant difference between in-game and post-test ($p = 0.445$) indicates that gains persist after gameplay.

Table 4: Paired-samples t-test results for learning in *LesDilemmes*.

Comparison	Mean diff.	SD	t	N	p
Pre → Post	−0.789	0.706	−4.33	14	< .001
Game → Post	−0.233	1.188	−0.78	15	.445
Pre → Game	−0.491	1.056	−2.32	24	.029

Comparing adaptive (A) vs. non-adaptive (NA) versions (Table 5), the pre–post gain was 0.789 for A vs. 0.333 for NA ($p = 0.058$). Note that A participants had a lower pre-test baseline (1.70 vs. 2.18), which is partly explained by the NA group being older on average.

5.3 Emotional Impact of Adaptation

Fig. 3 compares emotional profiles between conditions. The adaptive version yields significantly higher valence ($p < 0.001$), confirming that adaptation rules oriented toward positive affect were effective despite the reading-heavy nature of the

Table 5: Adaptive (A) vs. non-adaptive (NA) comparison.

Measure	Version	N	Mean	SD
Pre→Post gain	A	15	0.789	0.706
	NA	29	0.333	0.749
Pre-test	A	15	1.700	0.575
	NA	29	2.178	0.675
Post-test	A	16	2.536	0.684
	NA	29	2.511	0.648

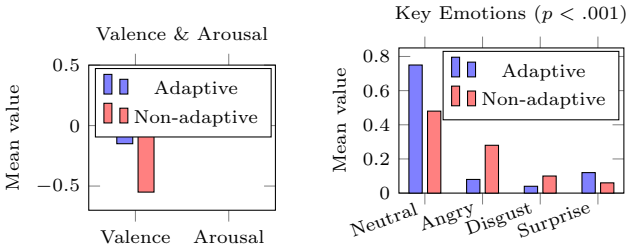

Figure 3: Emotional comparison between adaptive (A) and non-adaptive (NA) versions ($p < 0.001$). The adaptive version produces significantly higher valence, lower anger and disgust, and higher surprise.

game. The emotions neutral and anger are typically more prevalent during reading activities and tend to manifest with greater intensity when measured via Facereader [18]. In *LesDilemmes*, the predominant activity is reading—especially true in the adaptive version with additional learning and encouragement messages—and the main character has no direct control over the environment, only making decisions and evaluating others through button clicks. Therefore, negative emotions being more frequent than positive ones is entirely expected. Anger and disgust were significantly reduced in the adaptive condition, while neutrality and surprise increased. Surprise is particularly relevant: research shows surprising stimuli are remembered faster and recalled more accurately [7], and it promotes deeper cognitive engagement [2].

6. ADAPTATION RULES

A central contribution of this work is the translation of NN-derived patterns and decision tree thresholds into concrete, actionable rules deployed in *LesDilemmes*. Table 6 summarizes the five main rules implemented in the adaptive version, along with their source (NN or DT), the targeted learner state, and the game action triggered.

These rules complement expert-defined rules by targeting emotional regulation as a primary lever—an aspect absent from the original design. The NN-derived rules are globally stable (extracted from 20 runs), making them robust to stochastic training variability and suitable for deployment without per-learner retraining.

7. DISCUSSION

A key insight of this work is that architectural constraints can play a central role in making neural models usable in educational settings. Rather than relying on post-hoc interpretability, constraining the hypothesis space enables the

Table 6: Operationalized adaptation rules in *LesDilemmes*.

Condition	Source	Game Action	Goal
Valence < 0	NN (arousal)	Switch to cheerful music	Mood lift
Valence ≥ 0	NN (valence)	Play soft background music	Maintain state
Agrees with NPC $r_n > r_p$	Expert rule	NPC shows happy face + thumbs-up	Reinforce
$r_p < 4$	Expert rule	Display encouraging + scaffolding message	Scaffold
Player skips NPCs 2 or 5	NN (Eval 2/5)	Force exploration of remaining NPCs	Ensure exposure

extraction of stable and pedagogically meaningful rules that can be directly operationalized.

7.1 Interpretability by Design

A key methodological contribution of this work is the distinction between *intrinsic* and *post-hoc* interpretability. Techniques such as LIME [12] and SHAP [10] explain individual predictions after training, providing local approximations that may vary across instances. In contrast, non-negative weight constraints make the trained model itself interpretable at a global level: because all weights $w_i \geq 0$ and inputs $x_i \in [0, 1]$, the relative magnitude of weights directly encodes feature importance without auxiliary approximation.

This property is especially valuable in educational contexts, where adaptation rules must be stable, auditable, and pedagogically justifiable. A rule derived from a globally consistent model carries more credibility for instructional designers than a saliency map computed locally for a single learner episode.

7.2 Role of Emotions in Socio-Moral Learning

The prominence of affective features—particularly arousal, surprise, and happiness—in predicting reasoning level has important theoretical implications. It aligns with the cognitive-affective learning model [19], which posits that emotional states modulate attention, working memory, and long-term retention. High arousal without positive valence can hinder deliberate reasoning, while moderate arousal paired with positive affect creates an optimal state for engagement and higher-order thinking. Positive emotions also increase learner engagement, facilitate learning, and contribute to better long-term retention [13].

The observed increase in surprise in the adaptive condition is consistent with theories of *productive confusion* [7, 2]: unexpected feedback or NPC responses prompt learners to re-evaluate their assumptions, fostering deeper moral reflection. Designing NPCs to occasionally challenge learners with unexpected high-level reasoning—rather than always providing confirmatory feedback—may therefore be a principled lever for supporting reasoning progression.

7.3 Comparison with Related Approaches

Unlike deep knowledge tracing [11], which models latent skill states through LSTM networks but provides little interpretability, our constrained MLP explicitly surfaces which input dimensions drive predictions. Compared to Bayesian student models [6], which require strong prior assumptions, our approach learns directly from multimodal data without structural priors, while still producing transparent outputs. The hybrid NN–decision tree pipeline combines the representational power of neural learning with the symbolic clarity of tree-based rules—a complementary strategy supported by recent work on rule extraction from neural networks [8]. Unlike narrative personalization [20] and goal recognition [9] approaches that require manually authored rules, our rules emerge directly from data via the constrained architecture, making the approach scalable to new game contexts.

7.4 Limitations and Future Directions

Several limitations constrain the generalizability of the current results. First, the sample size ($N = 29$, yielding 261 observations) is small. Results should therefore be interpreted cautiously given the limited sample size and group differences, and viewed as preliminary evidence of the effectiveness of the extracted adaptation rules. Furthermore, the marginal significance of the adaptive gain ($p = 0.058$) warrants cautious interpretation. A pre-registered, adequately powered study is needed to confirm the learning benefit of adaptation. Second, the reasoning level labels depend on automatic speech transcription (Google Speech-to-Text) followed by algorithmic coding, introducing noise that could affect both model training and outcome measurement. Third, the age heterogeneity of participants (8–18 years) introduces developmental variance that may interact with adaptation mechanisms in ways not yet captured by the model.

Future work will address these limitations through: (1) larger and more homogeneous samples stratified by age group; (2) improved multimodal fusion incorporating gaze and physiological signals alongside facial expressions; (3) online model updating to enable within-session personalization rather than rule extraction from a fixed prior dataset; and (4) extension of the framework to other serious game contexts beyond socio-moral reasoning, such as scientific argumentation and collaborative problem-solving.

7.5 Broader Implications for Adaptive ITS

A key insight is that architectural constraints shift the neural model from a predictive black box to a knowledge elicitation mechanism, yielding stable, operationalizable rules without post-hoc interpretability. Three implications follow for adaptive ITS. First, interpretability and predictive power need not be traded off: 65–70% accuracy is maintained alongside globally consistent importance rankings. Second, the modular pipeline—NN for *which* features matter, decision tree for *when* and *at what thresholds*—allows independent updates as data or targets change. Third, globally extracted rules (20 averaged runs) are robust to stochastic variability, enabling real-time deployment without per-session retraining. The approach generalizes to any multimodal dataset with a learner outcome variable: architecture

choices adapt to available sensors while the non-negativity constraint preserves interpretability by construction.

8. CONCLUSION

This paper introduced a data-driven pipeline for extracting actionable adaptation rules from a constrained multimodal neural network in a game-based learning context. By enforcing non-negative weight constraints, the architecture transforms the NN into a globally interpretable aggregation mechanism whose weights directly encode feature importance across emotional, interactional, and gameplay modalities—without relying on post-hoc approximations.

Applied to *LesDilemmes*, the approach identifies arousal, surprise, and happiness as dominant predictors of higher socio-moral reasoning, and interactions with NPCs at levels 2 and 5 as the most informative social levers. These findings, validated by a decision tree analysis, were operationalized into five concrete adaptation rules governing background music, NPC feedback, and player navigation.

Empirical evaluation demonstrates that the resulting adaptive version shows larger pre–post learning gains with marginal statistical significance ($p = 0.058$; adaptive gain 0.789 vs. 0.333 for non-adaptive), substantially improves emotional climate ($p < 0.001$), and generates higher levels of surprise—an emotion associated with deeper cognitive engagement and better retention.

Beyond the specific game context, this work demonstrates that constraining neural architectures can transform them into interpretable rule extraction mechanisms, bridging the gap between data-driven learning and pedagogical design. This positions constrained multimodal neural networks as a practical and principled foundation for adaptive intelligent tutoring systems.

ABSTRACT

How does student–GenAI interaction quality vary with academic achievement? We introduce *coordination regimes*, a descriptive lens informed by the control-theoretic model of self-regulated learning, to characterize how students align cognitive goals, prompting actions, and inquiry phases in dialogue with GenAI. We coded 2,243 dialogue turns from 136 undergraduates along three dimensions (Learning Intention, Prompt Communicative Function, and Cognitive Presence) and analyzed them using Epistemic Network Analysis (ENA), Sequential Pattern Mining (SPM), and ANCOVA controlling for prior GPA. High achievers showed tighter co-occurrence structures linking reasoning, prompting, and resolution-oriented inquiry, while lower-achieving students more often exhibited what we term the *integration trap*: integration without enactment, in which students consolidate understanding without progressing to resolution. Sequential analyses further revealed "delegate-then-verify" patterns among high achievers versus "delegate-then-retreat" patterns among low achievers. Artifact Submission (students returning with execution results for AI diagnosis) showed the largest group difference ($\chi^2 = 31.83$, $p < .001$) and emerged as a promising scaffolding target. After controlling for prior GPA, learning intention differences were attenuated, whereas cognitive presence differences remained significant ($p = .011$), suggesting that the enactment layer of student–GenAI interaction may be partially distinct from prior academic ability and potentially scaffoldable.

Keywords

Generative AI, Student-AI Interaction, Epistemic Network Analysis, Sequential Pattern Mining, Learning Analytics

1. INTRODUCTION

Generative AI (GenAI) tools offer new possibilities for personalized learning support [8, 10]. As these tools become embedded in coursework, a central question is not simply whether students use GenAI, but how interaction quality differs across learners. Prior work has examined student–AI interaction through isolated lenses: prompt types and usage frequencies [11, 4, 14], co-occurrence structures [9], or learner profiles [7]. These approaches yield useful insights but typically treat cognitive goals, communicative actions, and inquiry processes as separate targets.

This separation limits what we can learn about interaction quality. Effective student–GenAI interaction is not reducible to asking higher-level questions, using particular prompt forms, or reaching later inquiry phases in isolation. Rather, it depends on how these elements work together as a coordinated system during dialogue. To capture this, we introduce *coordination regimes*, a descriptive analytic lens informed by the control-theoretic model of self-regulated learning [3, 15, 17]. In this model, goal-directed learning involves a *reference value* (the goal), an *output function* (the action taken), and an *input function* (monitoring progress) [3]. We operationalize these functions as Learning Intention, Prompt Communicative Function (PCF), and Cognitive Presence, respectively (Figure 1). We call the resulting group-level pattern of code co-occurrences and sequential transitions across these three dimensions a *coordination regime*. The an-

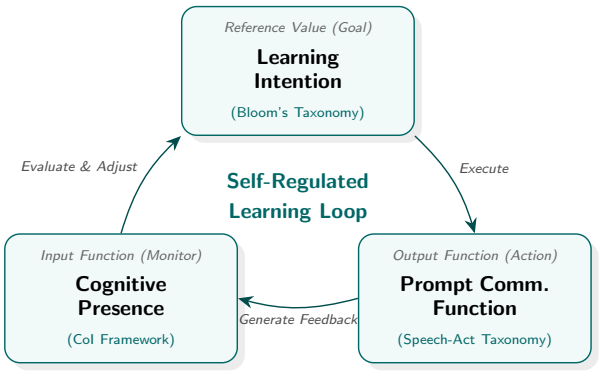

Figure 1: Operationalization of the control-theoretic SRL feedback loop. Each regulatory function is mapped to a conversational variable.

alytic value lies not in proposing new categories for Bloom's taxonomy or the Cognitive Presence framework, but in examining how goal, action, and monitoring indicators align or misalign within student–GenAI interaction.

We make three contributions. First, we offer *coordination regimes* as a conceptual lens for analyzing student–GenAI interaction as a coupled regulatory system rather than a set of independent variables. Second, we identify the *integration trap*, a recurring pattern in which lower-achieving students consolidate understanding without enacting or testing solutions. Third, we show that *Artifact Submission* (students returning with execution results for AI diagnosis) is a promising candidate target for enactment-aware scaffolding, supported by evidence that cognitive presence differences are not fully explained by prior academic ability.

We address three research questions:

RQ1. How do coordination regimes differ across achievement groups in the co-occurrence structure of Learning Intention, Prompt Communicative Function, and Cognitive Presence?

RQ2. How do turn-level sequential interaction patterns differ across groups?

RQ3. Do observed interaction differences persist after controlling for prior academic ability?

2. METHOD

The dataset comprised 136 third-year undergraduate students majoring in Statistics who were enrolled in a data mining course and used a GenAI assistant (Doubao, powered by ByteDance; a general-purpose conversational AI with code generation capabilities, comparable to ChatGPT in functionality) during Weeks 6–9 of a 16-week semester. The sample included 81 female students (59.6%) and 55 male students (40.4%). Students were stratified into three achievement tiers by final grade tertiles: G1 (High, $n = 52$), G2 (Mid, $n = 46$), G3 (Low, $n = 38$); smaller group sizes in lower tiers reflect more students excluded for absent or invalid dialogue records. The study was approved by the university ethics committee, and students provided informed consent for the use of their anonymized learning data. Dialogue records and grade information were de-identified before analysis, and all results are reported in aggregate. In total, 481 student-week observations containing 2,243 dialogue turns were collected. Each student contributed an average of 3.49 weekly observations ($SD = 1.04$).

Each turn was coded along three dimensions (Table 1). *Learning Intention* captures the prompt-expressed cognitive goal level (Remember through Create) via Bloom's revised taxonomy [2]. We use this term operationally to refer to enacted cognitive goals, not latent psychological intentions. *Prompt Communicative Function* (PCF) classifies prompts by their primary communicative function, i.e., what the student is trying to *do*, using six categories derived from speech act theory [12] and refined through pilot coding. *Cognitive Presence* captures the phase of inquiry via the Community of Inquiry framework [5]: Triggering, Exploration, Integration, and Resolution.

Inter-rater reliability was established on a random 20% sample ($n = 449$ turns) coded independently by two experts. Cohen's κ: Learning Intention = 0.72, PCF = 0.83, Cognitive Presence = 0.68. Disagreements were resolved through discussion, and the remaining turns were coded by the first author.

We used three complementary analyses. ENA [13] modeled co-occurrence structures (units: students; conversations: student-weeks; stanza window: entire conversation within each student-week; codes: 16 binary codes across three dimensions), capturing *which* codes connect within sessions. SPM [1] complemented ENA by capturing how codes unfold turn by turn; bigram and trigram frequencies were extracted from turn-level code sequences, expressed as proportions of all bigrams within each group, and compared across groups using chi-square tests with Benjamini–Hochberg correction (all p-values reported for SPM are BH-corrected). Groups were compared on ENA network positions using pairwise t-tests with Bonferroni correction. To test whether observed differences persisted beyond baseline ability, we ran ANCOVA controlling for prior-semester GPA. Together, these analyses aligned with the three research questions: ENA addressed RQ1 by comparing group-level co-occurrence structures, SPM addressed RQ2 by comparing turn-level bigram and trigram patterns, and ANCOVA addressed RQ3 by testing whether group differences persisted after controlling for prior-semester GPA.

3. RESULTS

3.1 Co-occurrence Structure (RQ1)

At the learning-intention dimension, differences were present but modest at the structural level, with stronger contrasts emerging in sequential analyses reported later. ENA networks showed that high achievers (G1) formed stronger connections along the Understand–Apply–Evaluate chain, while G2 and G3 showed more evenly distributed connections among lower-level goals (Remember–Understand–Apply) without reaching Evaluate (Figure 3). Group differences on ENA's primary dimension (SVD1) were not statistically significant after Bonferroni correction (G1 vs. G2:

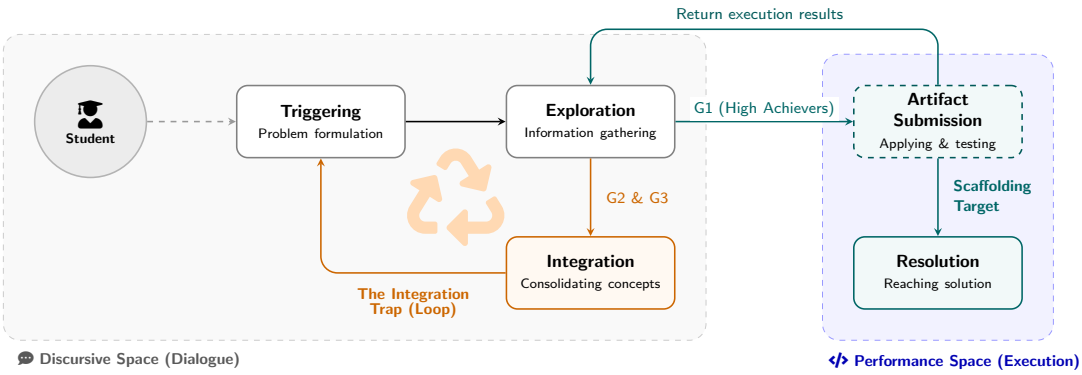

Figure 2: Conceptual model mapping the Integration Trap within the discursive space, and the pathway to resolution via Artifact Submission in the performance space. (G1, G2, and G3 refer to High, Mid, and Low achievement groups, respectively).

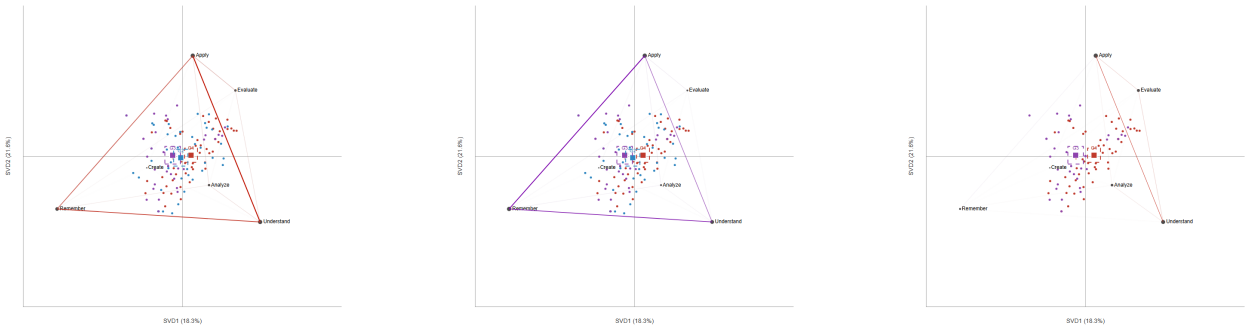
Table 1: Coding Framework: Three Dimensions of Student–GenAI Interaction

Dimension	Code	Definition	Source
Learning Intention	Remember	Recall or recognize factual information	Bloom's Revised Taxonomy [2]
	Understand	Explain or summarize concepts	
	Apply	Use knowledge in a concrete task	
	Analyze	Break down or compare components	
	Evaluate	Judge, test, or diagnose outputs	
	Create	Design or produce original artifacts	
Prompt Comm. Function (PCF)	Knowledge Query (KQ)	Ask for factual or conceptual information	Speech Act Theory [12]
	Task Delegation (TD)	Request AI to perform a task (e.g., write code)	
	Contextualized Query (CQ)	Query grounded in student's own context	
	Artifact Submission (AS)	Submit execution output for AI diagnosis	
	Elaboration (EF)	Follow up or refine a prior exchange	
	Output Shaping (OS)	Request format or style changes to output	
Cognitive Presence	Triggering	Recognize a problem or sense of puzzlement	Community of Inquiry [5]
	Exploration	Search for information or alternatives	
	Integration	Connect ideas into a coherent understanding	
	Resolution	Apply or test the solution in practice	

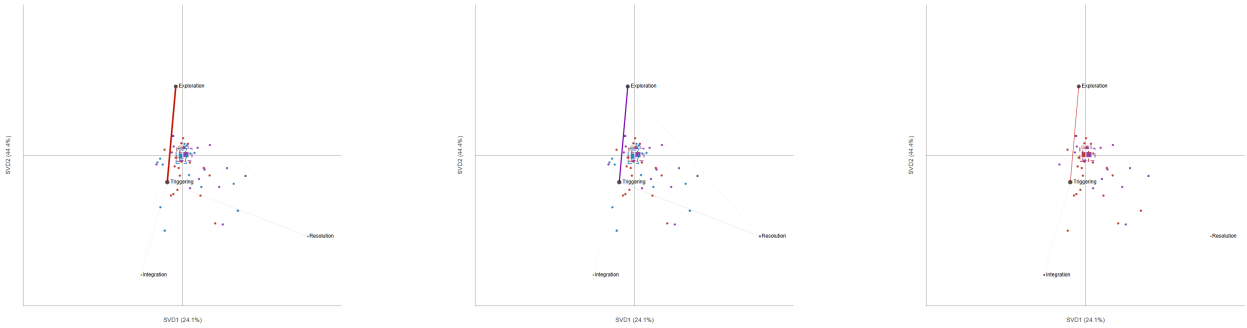
$d = 0.40$, $p = .050$; G1 vs. G3: $d = 0.40$, $p = .061$; G2 vs. G3: n.s.), consistent with the ANCOVA attenuation reported in RQ3.



At the prompt-function dimension, five of the six PCF codes differed significantly across achievement groups (Table 2), but Artifact Submission (AS) stood out as the clearest behavioral marker. In AS turns, students submit their own execution results, such as error messages or code output, for AI diagnosis. AS showed the largest group difference of any code across all three dimensions (G1: 14.5%, G3: 5.1%, $\chi^2(2) = 31.83$, $p < .001$). This finding is reinforced by cross-dimensional patterns: 51.0% of AS turns co-occurred with Evaluate-level intentions and 6.9% reached the Resolution phase. By contrast, Knowledge Query, the most common PCF code overall, was dominated by Remember and Understand (77.9%), with Resolution near-absent (0.2%).

At the cognitive-presence dimension, the clearest structural separation across achievement groups appeared in inquiry-phase patterns, where lower-achieving students were displaced toward Integration rather than Resolution. ENA networks showed that high achievers (G1) leaned toward Resolution, whereas G2 and G3 clustered near Integration (Figure 4). These structural differences along the primary network dimension (SVD1) were statistically significant after Bonferroni correction (G1 vs. G2: $d = 0.64$, $p = .002$; G1 vs. G3: $d = 0.55$, $p = .011$; G2 vs. G3: n.s.). This provides evidence for what we term the *integration trap*: lower-achieving students sustained inquiry cycles but consolidated

Table 2: PCF Distribution by Achievement Group



PCF Code	G1	G2	G3	$\chi^2(2)$	V
Knowledge Query	54.5%	65.9%	63.9%	26.78***	.109
Task Delegation	17.1%	17.7%	23.0%	7.88*	.059
Artifact Submission	14.5%	9.2%	5.1%	31.83***	.119
Contextualized Query	6.7%	3.0%	1.1%	28.40***	.113
Elaboration	6.0%	4.2%	5.5%	2.71	.035
Output Shaping	1.4%	0.0%	1.3%	9.14*	.064

Note. $^{*}p < .05$; $^{***}p < .001$. V = Cramér's V.

Figure 3: Learning Intention ENA. (a–b) Mean networks for G1 and G3; (c) contrast highlighting modest structural differences along the Understand–Apply and Apply–Evaluate edges.

(a) G1 (High Achievers) (b) G3 (Lower Achievers) (c) Contrast (G1 − G3)

Figure 4: Cognitive Presence ENA. (a–b) Mean networks for G1 and G3; (c) contrast showing G3's displacement toward Integration, illustrating the integration trap.

understanding rather than testing solutions in practice, a pattern of *integration without enactment*.

Despite these group differences, 75.1% of all coded turns remained in the Triggering phase across all groups, with Integration (3.2%) and Resolution (4.4%) rarely observed, consistent with prior findings that cognitive presence frequently stalls at lower phases [6].

3.2 Sequential Patterns (RQ2)

Sequential analyses revealed sharper contrasts, clarifying how coordination regimes unfold turn by turn.

For Learning Intention sequences, Understand→Apply appeared at 24.7% in G1 versus 8.6% in G3, and Apply→Evaluate at 20.1% versus 7.5%, indicating that high achievers progressed upward through Bloom's levels within their dialogues while lower achievers remained at foundational levels.

For prompt sequences, the contrasts were even sharper. TD→AS ("delegate-then-verify") occurred in G1 at four times the rate of G3 (3.7% vs. 0.9%, $p = .009$). Sustained debugging chains (AS→AS→AS) were present in G1 (3.5%) but entirely absent in G3. Conversely, TD→KQ ("delegate-then-retreat") was most frequent in G3 (12.1% vs. 5.6% in G1, $p < .001$). These patterns indicate that high achievers close the loop by verifying AI-generated solutions, while lower achievers return to conceptual questioning.

3.3 Does Prior Ability Explain the Differences? (RQ3)

To test whether these differences merely reflect pre-existing ability, we ran ANCOVAs controlling for prior-semester GPA.

The two dimensions behaved differently once baseline ability was accounted for. Learning Intention differences were no longer significant ($F(2, 132) = 2.30$, $p = .104$, $\eta_p^2 = .034$): *what* students asked about largely reflected their pre-existing competence. By contrast, Cognitive Presence differences remained significant ($F(2, 132) = 4.70$, $p = .011$, $\eta_p^2 = .066$): *how* students navigated the inquiry process differed across groups even after controlling for ability. That is, the group effect was fully attenuated for Learning Intention but retained for Cognitive Presence, suggesting that the enactment dimension of the coordination regime is not simply a by-product of prior ability and may be open to scaffolding.

4. DISCUSSION AND IMPLICATIONS

This study argues that differences in student–GenAI interaction are best understood as differences in *coordination regimes* (Figure 2). Lower-achieving students more often

exhibited the *integration trap*: consolidating understanding without enacting or testing solutions. Higher-achieving students more often closed the loop through *Artifact Submission*, returning with execution results that enabled diagnosis and movement toward resolution.

The ANCOVA results suggest a dimension-specific interpretation. Learning Intention differences were attenuated after controlling for prior-semester GPA, whereas Cognitive Presence differences remained, consistent with the possibility that goal selection is more tightly coupled to prior competence while enactment is not fully explained by prior ability and may be open to scaffolding. At the same time, our observational design does not support strong causal claims, and future experimental work is needed to test whether scaffolding enactment changes learning behavior or outcomes.

These findings have practical implications for learning analytics and GenAI-supported instruction. In particular, Artifact Submission appears promising as an observable trace-level marker and candidate design target because it is visible in dialogue logs, detectable automatically, and potentially responsive to real-time nudges. Rather than focusing only on prompt engineering [14, 16], educators and systems might test scaffolds that encourage enactment: running code, testing outputs, bringing back errors, and iterating on concrete artifacts. More broadly, assessment may need to place greater value on artifacts of enactment (such as tested code or verified outputs) than on artifacts of inquiry alone, such as chat transcripts.

4.1 Limitations and Future Work

While this study identifies coordination regimes in student–GenAI interaction, several boundary conditions should be considered. The study was conducted in a coding-heavy data mining course, where Artifact Submission often involved executable code, error messages, or output traces; future work should examine whether analogous enactment markers appear in less technical learning contexts. The measures also relied on dialogue logs. Learning Intention therefore captures prompt-expressed cognitive goals rather than latent psychological intentions, and the PCF coding scheme, although pilot-refined and reliable in this dataset, requires further validation across learning domains. Because achievement groups were defined within a single course, future studies should examine whether similar coordination patterns appear across courses, institutions, and learning tasks. Experimental work is also needed to test whether enactment-aware scaffolds change interaction patterns and learning outcomes.

ABSTRACT

Detecting cognitive-affective states in collaborative problem-solving is challenging due to their subjective nature, social regulation, and the complexity of multiparty speech. While prior work has largely relied on observer-coded labels in individual learning contexts, self reported states may capture internal experiences that learners regulate and do not outwardly express, precisely the states where intervention could be most valuable. We investigate whether conversational speech alone provides sufficient signal to detect self reported cognitive-affective states during collaborative problem solving. Using retrospective video-cued recall, we obtained labels for seven states (Optimistic, Confused, Curious, Disengaged, Surprised, Frustrated, and Conflicted) from 27 participants (9 groups) completing a collaborative task. We systematically compared prosodic features (eGeMAPS) and semantic embeddings (SentenceTransformers) across multiple temporal window sizes using Leave One Group Out cross validation. Four of seven states were detectable above chance with statistical significance (permutation $p < 0.05$), with AUROCs ranging from 0.570 to 0.618. The remaining three states showed promising trends but did not reach significance, likely due to limited statistical power. No single feature modality dominated across states, and optimal detection windows varied substantially, from 5 seconds for transient states like Confused to 30 seconds for sustained states like Frustrated. These findings suggest that meaningful signal for self-reported affective states exists in conversational speech during collaborative problem-solving, motivating further investigation with larger samples and richer feature representations.

Collaborative problem-solving (CPS) is a learning paradigm where two or more individuals work together to achieve a shared goal [1]. Through CPS, learners engage in social interactions such as joint reasoning, finding common ground, and coordination of strategies, which require the regulation of cognitive-affective states such as confusion and conflict. Prior research has shown that such states influence both group performance and individual learning outcomes [2]. Therefore, automatically detecting cognitive-affective states during collaborative problem-solving is useful for adaptive educational technologies to better support learners in real time.

However, automatic detection of these states in collaborative settings remains challenging. Prior work on affect detection has largely focused on individual learning contexts, where confusion and frustration can be inferred from dialogue in intelligent tutoring systems [3, 4], and multimodal signals including speech, facial expression, and gaze have improved detection [5–7]. Collaborative learning introduces additional complexity: speech overlaps and social masking make it difficult to map behavioral signals to affective states, and observable behavior does not always align with subjective experience. To obtain more ecologically valid labels, Anindho et al. [8] used retrospective cued-recall to capture cognitive-affective labels aligned to collaborative interaction, providing access to internally experienced states that may not be externally observable. Although retrospective labeling may introduce recall bias and some temporal imprecision, it may provide access to subjective states that are not captured by external observation. This brings forth an interesting question about the relationship between subjective states and observable behavior: how does self-reported affect manifest in external signals such as speech in collaborative problem-solving? To address this, we turn to a naturalistic collaborative setting in which both speech and self-reported states can be examined together.

This paper investigates the automatic detection of seven self-reported cognitive-affective states: Optimistic, Confused, Curious, Disengaged, Surprised, Frustrated, and Conflicted, from audio recordings of 27 participants (nine groups) completing a collaborative problem-solving task. Using retrospective video-cued self-report labels, we systematically compare prosodic features (eGeMAPS) and sentence embeddings (SentenceTransformers) across four temporal window sizes (5s, 10s, 20s, 30s). Our results establish preliminary baseline detection performance for each state, revealing that

four states show reliable above-chance detection (permutation $p < 0.05$): Optimistic, Curious, Disengaged, and Confused. Three additional states—Frustrated, Conflicted, and Surprised—have confidence intervals above chance, though statistical power limitations suggest these findings are preliminary. We find that no single feature modality dominates across all states, and that optimal temporal windows vary systematically by state (ranging from 5 seconds for Confused to 30 seconds for Frustrated). Despite the inherent difficulty of detecting subjective internal states from speech alone, our results demonstrate that meaningful signal exists in conversational audio for multiple cognitive-affective states, establishing an initial baseline for self-report-driven affect detection in collaborative learning environments.

2. METHODS

2.1 Participants and Task

This study examines 27 participants who were older than 18 and all fluent in English. They were recruited from the author's department with approval from the Institutional Review Board and compensated with 15 USD. The sample included 18 male, 7 female, and 2 non-binary participants, who self-identified as Asian (13), White (12), or Hispanic (2). Participants were organized into nine collaborative groups, with three participants per group. Each group completed the first part of the Weights Task, which is a collaborative problem-solving activity from Khebour et al. [9] in which participants are given five blocks, a balance scale, and told that one block weighs 10 grams. Their task is to determine the weights of the remaining four blocks through collaborative experimentation and reasoning. The task requires coordination, hypothesis testing, and shared decision-making, naturally eliciting a range of cognitive-affective states as participants encounter uncertainty, disagreement, and discovery [9]. Participants provided written consent from each participant and were informed that their audio and video recordings would be used for research purposes. Recordings are stored on secure, access-controlled servers and transcripts were de-identified prior to analysis. Figure 1 shows one of the groups collaborating during the problem-solving activity.

Figure 1: Our experimental setup during a collaborative problem solving session

2.2 Annotation of Cognitive-Affective States

Cognitive-affective states were annotated using retrospective video-cued recall. After completing the task, each participant individually watched a recording of their collaborative session and marked instances where they experienced specific cognitive-affective states. Seven states were adopted from previous research [10] and were made available for selection: Optimistic, Confused, Curious, Conflicted, Frustrated, Surprised, and Disengaged. Participants could report multiple states concurrently if they experienced overlapping cognitive-affective responses. Each annotation generated a timestamp aligned to the video timeline, along with participant and group identifiers. Annotations were completed independently to avoid social influence, and no external coders were involved in labeling. The resulting dataset therefore reflects participants' subjective, post-hoc recall of their internal cognitive–affective experience, rather than behavioral interpretations assigned by observers. An example conversational segment is presented below. Participant 3 labeled this moment as Frustrated.

> **P1:** So what if we tried 40? Which one did we say was 30?
> **P2:** Purple.
> **P1:** Perfect.
> **P1:** Okay, incorrect. So it is 50.

This segment illustrates the challenge of detecting internal states from speech alone: P1's self-reported frustration is not explicitly verbalized, and the prosodic signature must be extracted from brief utterances ("Okay, incorrect. So it is 50") that occur in the context of ongoing collaboration. The detection task requires distinguishing such moments from similar task-focused utterances spoken without frustration. Table 1 presents the distribution of labeled samples across states and window sizes. The distribution is imbalanced, with Optimistic and Confused being the most frequent states and Surprised, Disengaged, and Frustrated each having fewer than 20 samples. Windows are centered on the point of self-report: a 5-second window includes 2.5 seconds before and 2.5 seconds after the reported moment, a 10-second window includes 5 seconds before and after, and so on. We exclude any window without an associated transcript (i.e., periods of group silence). As window size decreases, the number of such samples increases.

Table 1: Number of positive samples per cognitive-affective state across four temporal window sizes.

State	5s	10s	20s	30s
Optimistic	73	81	88	90
Confused	57	58	58	59
Curious	42	49	52	54
Conflicted	18	19	19	19
Frustrated	16	16	16	16
Surprised	15	15	16	16
Disengaged	15	18	20	21
Total labeled	**236**	**256**	**269**	**275**

2.3 Feature Extraction

Prosodic features. Each participant wore an individual microphone, providing speaker-separated audio. We extracted

88 features using the eGeMAPS feature set via openSMILE [11], including F0 statistics, loudness, spectral features, voice quality measures (jitter, shimmer, HNR), and temporal descriptors. Features were computed over each temporal window.

Transcript features. Speech was transcribed using Whisper [12] and segmented into temporal windows. We obtained 768-dimensional sentence embeddings using `all-mpnet-base-v2` from SentenceTransformers [13], which outperformed BERT `[CLS]` embeddings across states.

Combined features. We additionally concatenated prosodic and transcript vectors (856 dimensions).

2.4 Classification Framework

We framed detection as a set of binary one-vs-rest classification problems, training a separate classifier for each of the seven cognitive-affective states. For each state, the positive class consisted of all windows labeled with that state (using the primary label only), and the negative class was formed by randomly sampling from all non-target windows at a 1:1 ratio. The negative class for each state consists of randomly sampled non-target windows, including both unlabeled windows and windows labeled with other states, to allow for a balanced dataset. This formulation tests whether each state has a discriminative signature that distinguishes it from both neutral collaboration and other affective states, a pragmatic choice for real-world affect detection systems that must distinguish target states from heterogeneous background activity. To reduce variance from negative sampling, we repeated the random undersampling with five different random seeds and averaged results across seeds. We evaluated Logistic Regression (L2, balanced weights), Random Forest (200 trees, balanced weights), and SVM with RBF kernel (balanced weights, Platt scaling). Features were standardized with parameters fit on training data only.

We used Leave-One-Group-Out (LOGO) cross-validation, holding out one group at a time, and report AUROC as the primary metric.

3. RESULTS

We report classification performance using AUROC as the primary metric, averaged across five negative resampling seeds. We report 95% bootstrap confidence intervals (2,000 iterations on pooled LOGO predictions) and permutation test p-values (1,000 iterations) to assess whether observed performance exceeds chance. Logistic Regression was the best or near-best model for the majority of configurations; we focus on Logistic Regression unless otherwise noted.

3.1 Detection Performance Across States

Table 2 reports the best AUROC per state across all window sizes and modalities, along with the optimal modality/window and permutation p-values. Three states met a significance criterion of CI excluding 0.50 and permutation $p < 0.05$: Optimistic (0.607, $p = 0.004$), Curious (0.600, $p = 0.016$), and Disengaged (0.618, $p = 0.023$). Confused reached significance at 5 seconds (0.570, $p = 0.049$). The remaining states of Frustrated (0.634), Conflicted (0.623), and Surprised (0.613), had CIs above chance but permutation p-values between 0.10 and 0.14, reflecting limited power with a 9-fold LOGO design. We additionally evaluated late fusion (averaging classifier probabilities from prosodic-only and transcript only models) and learned fusion (training a meta-classifier on concatenated probability outputs). Neither approach improved over the better single modality (mean AUROC difference: -0.01 for late fusion, $+0.00$ for learned fusion), suggesting that prosodic and linguistic features are largely redundant rather than complementary for most states.

Table 2: Best AUROC per state, with the corresponding optimal modality/window and permutation p-values.

State	n	AUROC	Modality	Window	p
Frustrated	16	0.634	Prosodic	30s	.108
Conflicted	18–19	0.623	Combined	30s	.136
Disengaged	15–21	0.618	Transcript	30s	.023
Surprised	15–16	0.613	Transcript	30s	.103
Optimistic	73–90	0.607	Transcript	10s	.004
Curious	42–54	0.600	Combined	20s	.016
Confused	57–59	0.570	Prosodic	5s	.049

Each state's optimal configuration differed in both temporal window size and feature modality. Across all 28 state–window combinations, transcript features were optimal 13 times, prosodic features 9 times, and combined features 6 times.

3.2 Effect of Temporal Window Size

Table 3 reports the best AUROC per state at each window size with bootstrap CIs. The optimal window varied substantially by state as seen by Figure 2. Four states achieved their best performance with 30 second windows (Frustrated, Conflicted, Disengaged, Surprised), while Optimistic peaked at 10 seconds and Confused at 5 seconds. Curious improved steadily from 5 to 20 seconds, then plateaued.

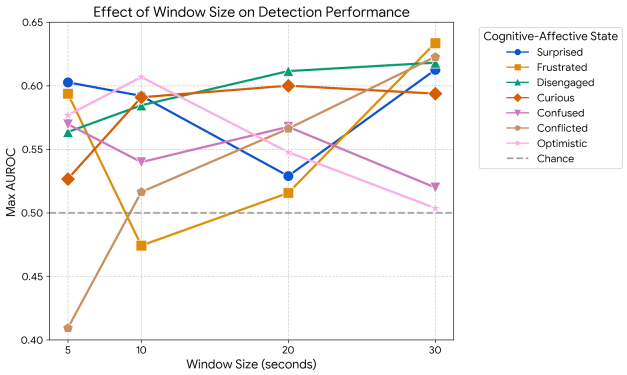

Figure 2: Interaction between temporal window size and detection performance. Max AUROC achieved for each state across 5s, 10s, 20s, and 30s windows. The crossing trajectories highlight distinct temporal dynamics: Optimistic and Confused decay with longer windows (suggesting transient expression), while Disengaged and Frustrated improve (suggesting sustained states).

The temporal trajectory differed qualitatively across states. Optimistic peaked early and declined ($0.577 \rightarrow 0.607 \rightarrow 0.548 \rightarrow 0.504$), with CIs excluding chance only at 5, 10, and 20 seconds. Curious showed consistent above-chance detection from 10 seconds onward, with significant permutation

Table 3: Best AUROC [95% CI] per state at each window size. Bold indicates the highest AUROC per state. † CI excludes 0.50; * permutation $p < 0.05$.

State	5s	10s	20s	30s
Frustrated	.594 [.51, .68]†	.474 [.39, .57]	.516 [.42, .61]	**.634** [.56, .72]†
Conflicted	.409 [.32, .49]	.516 [.44, .60]	.566 [.48, .63]	**.623** [.55, .70]†
Disengaged	.564 [.48, .66]	.585 [.50, .67]	.611 [.52, .68]†	**.618** [.54, .69]†*
Surprised	.603 [.51, .69]†	.592 [.49, .67]	.529 [.45, .63]	**.613** [.51, .69]†
Optimistic	.577 [.54, .62]†	**.607** [.57, .65]†*	.548 [.51, .58]†	.504 [.46, .54]
Curious	.527 [.47, .58]	.591 [.54, .64]†	**.600** [.55, .65]†*	.594 [.55, .64]†*
Confused	**.570** [.52, .62]†*	.540 [.49, .58]	.568 [.52, .62]†	.521 [.47, .56]

p-values at 20s ($p = 0.016$) and 30s ($p = 0.031$). Disengaged improved monotonically with window size but only reached significance at 30 seconds ($p = 0.023$).

4. DISCUSSION

This study investigated whether conversational speech contains sufficient signal to detect self-reported cognitive affective states during collaborative problem-solving. The central finding is encouraging: despite the inherent subjectivity of internal states and the social pressures that shape expression during collaboration, detectable signal exists for multiple states. We discuss the implications of this finding and directions for building on it.

4.1 Signal Exists for Subjective Internal States

We used *self-reported* labels capturing what participants said they internally experienced, rather than observer-coded labels capturing externally visible behavior. In collaborative settings, participants may regulate outward expression to maintain group harmony while still experiencing the underlying state [14, 15]. Our ability to still identify the signal despite this regulation suggests that speech-based detection of internal affective states during collaboration is feasible and worth further investment.

4.2 State-Specific Detection Configurations

A consistent finding across our systematic comparison is that each cognitive-affective state has a distinct optimal detection configuration. No single modality dominated: transcript embeddings were optimal for some states (Disengaged, Surprised, Optimistic), prosodic features for others (Frustrated, Confused), and the combination for two (Curious, Conflicted). Similarly, optimal temporal windows ranged from 5 seconds (Confused) to 30 seconds (Frustrated, Conflicted, Disengaged, Surprised).

The temporal patterns are particularly notable. Confused was best detected at short windows and degraded with longer context, while Frustrated and Disengaged improved monotonically up to 30 seconds. These patterns align with theoretical accounts distinguishing transient states from sustained episodes [16]—confusion as brief cognitive impasse that either resolves or escalates, frustration as accumulated difficulty over time. The state-specific temporal signatures suggest that affect detection systems for collaborative learning may need adaptive windowing strategies rather than fixed parameters.

The failure of multimodal fusion to improve over the best single modality (mean AUROC difference <0.01 across early, late, and learned fusion) indicates that prosodic and linguistic features are largely redundant for these states. This contrasts with typical findings in acted-speech emotion recognition [17], suggesting that the relationship between modalities may differ for self-reported states in naturalistic settings.

4.3 Limitations

The sample of nine collaborative groups limits both the reliability of leave-one-group-out estimates and the power of permutation tests, in addition to limiting generalization .

The retrospective self-report methodology introduces temporal imprecision and potential recall biases [18]. Participants may misalign labels when marking video, or preferentially recall salient moments. The binary one-vs-rest framing creates heterogeneous negative classes that include both unlabeled windows and windows labeled with other states.

Feature representations. Transcript embeddings were computed by concatenating all utterances within each window into a single string, which may not optimally capture turn-taking dynamics, overlapping speech, or the sequential structure of collaborative dialogue. Additionally, prosodic features were aggregated over fixed temporal windows, potentially missing finer-grained affective dynamics within windows.

Generalizability. Our findings are based on a single collaborative task (the Weights Task) with groups of three participants in a controlled laboratory setting. Task characteristics such as problem structure, duration, and social dynamics may influence which states emerge and how they are expressed. Detection performance may differ for other collaborative learning contexts (e.g., open-ended projects, peer tutoring, online collaboration) or different group sizes.

5. CONCLUSION

In this work, we used conversational speech to automatically detect self-reported cognitive-affective states during a collaborative problem-solving task, employing a retrospective video-cued recall approach to obtain affective labels without disrupting the task itself. Four of seven states were detectable above chance from prosodic and linguistic features alone: an encouraging result given the inherent subjectivity of internal states and the social regulation that characterizes collaborative settings. These results motivate future work incorporating richer features, additional modalities, and larger samples. We hope they inspire continued investment in self-report-driven approaches to affect detection in educational technology. We note that the intended application of this work is to assist educators and AI tutoring

systems in providing timely support; any deployment should ensure that inferred states are used to benefit the individual learner rather than for surveillance or social comparison.

ABSTRACT
This study investigates how task difficulty shapes learners' self-reported attention and multimodal exploratory behaviors in an extended reality (XR) diagnostic simulation. Twenty-one medical students completed three strabismus diagnostic subtasks of increasing difficulty (ocular motility, cover-uncover, and prism cover tests) while gaze and head movement data were continuously recorded alongside self-reported attention measured after each task. Results revealed asymmetrical divergence: self-reported attention declined significantly with task difficulty, while gaze path rate and head movement rate increased significantly. This compensation strategy indicates heightened cognitive demand. Critically, behavioral indicators carry context-dependent cognitive meanings, high exploratory activity does not uniformly signal engagement but may indicate struggle. These findings are essential for designing adaptive XR diagnostic systems that interpret behavioral signals appropriately.

Keywords
extended reality, task difficulty, attention, gaze behavior, head movement

1. INTRODUCTION
Extended Reality (XR) has gained traction as a training tool in high-stakes professional domains, offering learners a level of immersion and high contextual realism that conventional digital environments cannot replicate [1]. In clinical education, XR-based diagnostic simulations allow repeated practice of complex procedural skills in safe, controlled contexts, yet they also impose concurrent demands on visual attention, spatial navigation, and clinical reasoning that can strain learners' limited cognitive resources [2].

A key challenge in evaluating XR-based training is that most studies rely on post-task outcome measures, such as accuracy or scores, which offer limited insight into how learners allocate cognitive resources in real time. Gaze and head movement data captured continuously during task performance offer a more direct window into these moment-to-moment processes [4][5]. However, the relationship between behavioral indicators and cognitive states is not straightforward: as task demands rise, learners may simultaneously report declining attention while displaying increased exploratory effort, a behavioral compensation pattern whose meaning shifts with difficulty context [6].

The present study addresses this gap using a within-subjects design in an XR strabismus diagnostic simulation. We examine (1) how self-reported attention changes across three difficulty levels, (2) how gaze and head movement indicators vary with task difficulty, and (3) how the relationship between attention and exploratory behavior shifts depending on the difficulty context. By integrating subjective and objective behavioral measures, this study aims to provide a context-sensitive account of learner cognitive states in immersive clinical training.

2. THEORETICAL BACKROUND

2.1 XR Learning Environments and Cognitive Demands in Clinical Training
XR-based simulations have gained increasing attention in clinical education for their capacity to replicate realistic diagnostic scenarios while enabling safe, repeatable practice [2]. The Cognitive Affective Model of Immersive Learning (CAMIL) provides a theoretical account of how XR environments engage learners: technological features such as immersion and agency activate cognitive and affective processes, including cognitive load and self-regulation that mediate learning outcomes [1]. Critically, while immersion enhances engagement, it can simultaneously impose extraneous cognitive demands through the need to navigate three-dimensional space and coordinate visual and physical actions alongside core task performance. This dual nature makes it particularly important to characterize how learners' cognitive states change as task demands escalate within XR simulations.

2.2 Task Difficulty, Attention, and Behavioral Compensation
According to Cognitive Load Theory, human working memory is limited, and rising task complexity increases intrinsic load, progressively depleting the cognitive resources available for sustained attention [3]. As task demands increase, learners are expected to report decreased attentional focus, which can be reliably measured using validated subjective mental effort scales [7]. However, the relationship between subjective attention and observable behavior is not straightforward. Rather than reducing exploratory effort in

proportion to attentional decline, learners may instead intensify their visual and physical search to compensate for depleted cognitive resources, a pattern termed behavioral compensation [4]. Whether this compensatory pattern emerges, and how its meaning shifts with difficulty context, remains an underexplored question. Crucially, behavioral compensation is conceptualized here as a strategic redirection of behavioral effort when attentional resources are depleted, distinguishing it from random or fatigue-driven movement: learners actively intensify exploration to gather diagnostic cues despite reduced subjective attention [10, 11]. This framework predicts not only main effects of difficulty on both attention and behavior, but also a context-dependent reversal of their relationship at high difficulty, where preserved attentional capacity becomes increasingly coupled with strategic exploratory effort [12].

2.3 Multimodal Behavioral Indicators: Gaze and Head Movement

Eye gaze and head movement provide continuous, non-intrusive indices of cognitive dynamics during task performance that retrospective self-reports cannot capture [5]. Gaze path rate reflects the volume and spatial extent of visual exploration, while gaze speed variability indexes instability in information-seeking dynamics. In XR specifically, head translation path rate captures embodied spatial exploration, as learners must physically reposition themselves to acquire visual information within three-dimensional space [8]. Critically, the functional meaning of these indicators may vary depending on difficulty context: the same level of gaze exploration may reflect unfocused, scattered search at low difficulty, but strategic, resource-dependent search at high difficulty [6]. Integrating subjective attention with multimodal behavioral data is therefore essential for accurate cognitive assessment.

.

3. METHOD

3.1 Participants

Twenty-one medical students (13 males, 8 females; third- or fourth year) participated in this study. All had completed relevant ophthalmology coursework and practical training in strabismus prior to participation. The study was approved by the Institutional Review Board (No. 1040198-221021-HR-128-02).

3.2 Procedure and Task Design

Participants completed three strabismus diagnostic subtasks using a HoloLens 2 head mounted display, following a 10-minute familiarization session and eye-tracking calibration. The tasks were administered in a fixed order mirroring standard clinical workflow with progressive cognitive demands: (1) ocular motility test (Level 1; low difficulty), in which participants positioned themselves approximately 40 cm from the virtual patient and moved a fixation stick along an H-pattern while tracking the patient's eye movements to determine the presence of strabismus; (2) cover-uncover test (Level 2; medium difficulty), in which participants alternately covered each of the virtual patient's eyes with an occluder and observed refixation movements to identify both the presence and the type of strabismus; and (3) prism cover test (Level 3; high difficulty), in which participants placed a prism over the non-deviating eye while applying the occluder to the strabismic eye, then iteratively adjusted the prism degree until eye movement was no longer observed in order to quantify the angle of deviation. The progressive difficulty structure reflects escalating demands in visual search, pattern recognition, and procedural reasoning beyond passive vision screening, and is consistent with established clinical training standards and was validated by ophthalmology specialists. Trial duration was limited to three minutes for Levels 1 and 2, and five minutes for Level 3. A within-subjects design was employed, with each participant completing all three tasks.

3.3 Measures

*S*elf-reported attention was assessed immediately after each task using a 7-point Likert scale [9], where higher scores indicate greater attentional focus. Four behavioral indicators were derived from continuous XR tracking logs. *Gaze path rate* (GPR) and *gaze speed variability* (SD of instantaneous gaze speed) served as indices of visual exploration volume and stability, respectively, computed from frame-to-frame gaze hit position data. *Head movement rate* (HMR) and *head angular speed variability* (SD of angular speed) served as indices of embodied exploration, derived from head position and rotation quaternion data sampled at each frame.

3.4 Analysis

Task difficulty was treated as an ordered three-level predictor. To address RQ1 and RQ2, within-person dependence was accounted for using participant-level random-intercept linear mixed models (LMM), a participant fixed-effects approach was substituted when random-effects structures were not estimable. To address RQ3, Pearson correlations between self-reported attention and each behavioral metric were computed separately at each difficulty level to examine context dependent shifts in the attention and exploration relationship. All analyses were conducted in Python (Google Colab), with $\alpha = .05$.

Note on the dataset. A complementary descriptive analysis of the same XR strabismus simulation dataset has been reported in the proceedings of iLRN 2026 [13]. That prior work focused exclusively on comparing behavioral indicators across difficulty levels. The present study extends this work by introducing self-reported attention as a subjective cognitive measure, examining the difficulty-contingent relationship between attention and exploratory behavior, and interpreting findings through Cognitive Load Theory to propose a behavioral compensation mechanism.

4. RESULTS

Table 1 summarizes descriptive statistics and model-based effects for all five outcome variables across the three difficulty levels.

4.1 RQ1. Effects of Task Difficulty on Self-Reported Attention

Self-reported attention decreased significantly as task difficulty increased ($\beta = -0.184$, $p = .008$, LMM). Mean scores declined monotonically from 6.20 ($SD = 0.62$) at Level 1 to 6.06 ($SD = 0.74$) at Level 2 and 5.83 ($SD = 0.54$) at Level 3, confirming that learners experienced progressively greater cognitive strain across the three diagnostic subtasks.

4.2 RQ2. Effects of Task Difficulty on Exploratory Behavior

Increased task difficulty was associated with significant increases across three of the four behavioral indicators. Gaze path rate rose approximately 2.85-fold from Level 1 to Level 3 ($\beta = 0.32$, $p < .001$, LMM), indicating that learners engaged in substantially broader visual scanning under higher demand. Gaze speed variability also increased significantly ($\beta = 0.78$, $p = .010$, fixed effects), reflecting greater instability in visual search dynamics. Head movement rate similarly increased with difficulty ($\beta = 0.01$, $p < .001$, fixed effects),

suggesting that learners engaged in greater physical repositioning as diagnostic demands escalated. Head angular speed variability showed an increasing trend but did not reach statistical significance (β = 0.04, p = .100). Together, these results indicate that despite declining subjective attention, learners intensified their exploratory effort across difficulty levels, a pattern consistent with behavioral compensation under increasing cognitive load. Notably, while the decline in self-reported attention was modest (5.9% reduction across levels), behavioral indicators showed substantially larger relative increases (gaze path rate: 185%; gaze speed variability: 50%; head movement rate: 50%), suggesting that objective behavioral metrics may capture cognitive demand shifts more sensitively than subjective reports.

4.3 RQ3. Difficulty-Contingent Shifts in the Attention–Exploration Relationship

The relationship between self-reported attention and GPR shifted in direction across difficulty levels (Table 2). At Levels 1 and 2, negative correlations were observed (r = -0.217 and r = -0.176, respectively), indicating that learners reporting lower attention exhibited broader visual exploration patterns, consistent with unfocused, scattered search. In contrast, at Level 3, the correlation reversed to positive (r = 0.342), despite a statistically significant decline in mean attention across the cohort (L1: M = 6.20 → L3: M = 5.83, β = -0.18, p = .008). This reversal is notable: the substantial increase in mean GPR (from 0.34 at L1 to 0.97 at L3) coincided with decreased attention, suggesting that visual exploration intensity increased not because of greater attentional resources, but possibly due to heightened task demand. Within this constrained attentional environment, the positive correlation (r = 0.342) indicates that learners who retained relatively higher attention tended to exhibit more extensive gaze-based exploration, a pattern consistent with a compensatory mechanism whereby preserved attentional capacity is redirected toward broader information gathering.

For HMR, negative correlations persisted across all three levels (Level 1: r = -0.182; Level 2: r = -0.300; Level 3: r = -0.055), with magnitude substantially attenuated at Level 3. This progressive dissociation between attention and head-based exploration under increasing demand suggests that gaze became the primary behavioral marker of cognitive resource allocation at peak difficulty, whereas head movement decoupled from attentional availability, possibly reflecting a shift toward more efficient, gaze-centered diagnostic strategies.

Table 1. Descriptive Statistics and Model Effects by Task Difficulty

Outcome	L1 M (*SD*)	L2 M (*SD*)	L3 M (*SD*)	β	p	Model
Attention	6.20 (0.62)	6.06 (0.74)	5.83 (0.54)	−0.18	.008	LMM
Gaze path rate	0.34 (0.22)	0.77 (0.52)	0.97 (0.84)	0.32	<.001	LMM
Gaze speed variability	2.88 (1.07)	4.13 (1.92)	4.33 (2.65)	0.78	.010	Fixed
Head movement rate	0.02 (0.01)	0.03 (0.01)	0.03 (0.02)	0.01	<.001	Fixed
Head rotation variability	0.15 (0.10)	0.22 (0.11)	0.23 (0.22)	0.04	.100	Fixed

Note. L1 = ocular motility; L2 = cover–uncover; L3 = prism cover. β = unstandardized coefficient. LMM = linear mixed model. Fixed = participant fixed effects.

Table 2. Pearson Correlations Between Attention and Exploratory Metrics by Difficulty Level

	Level 1	Level 2	Level 3
Attention – GPR	−0.217	−0.176	+0.342
Attention – HMR	−0.182	−0.300	−0.055

Note. GPR = gaze path rate; HMR = head movement rate. Bold indicates direction reversal.

5. DISCUSSION AND CONCLUSION

This study examined how task difficulty shapes self-reported attention and multimodal exploratory behaviors in an XR diagnostic simulation, and how the relationship between these measures shifts with difficulty context.

5.1 Declining Attention and Behavioral Compensation

Consistent with Cognitive Load Theory [3], self-reported attention declined monotonically as diagnostic task demands escalated. Concurrently, gaze path rate and head movement rate increased significantly, presenting an asymmetrical pattern in which subjective attentional resources were depleted while behavioral exploratory effort was amplified. This divergence is interpretable as a behavioral compensation strategy: despite declining attentional capacity, learners persistently expanded their visual search for diagnostic cues. The finding underscores that behavioral quantity (gaze/head movement) and attentional quality (self-reported focus) do not move in tandem, and that exploration metrics alone may misrepresent cognitive engagement without accounting for difficulty context and concurrent attentional constraints. An alternative interpretation, that increased eye movements at higher difficulty reflect visual strain rather than cognitive compensation, is less consistent with the observed selective patterns: gaze path rate increased significantly while head rotation variability did not, and the GPR–attention correlation reversed at Level 3 — patterns not predicted by a fatigue-based account[11].

5.2 Difficulty-Contingent Reversal of the Attention–Exploration Relationship

The most theoretically significant finding is the reversal of the attention−GPR correlation at Level 3. At lower difficulty levels, lower attention was associated with broader exploration, consistent with unfocused, scattered search. At the highest difficulty level, this relationship reversed within a substantially constrained attentional environment. Within this depleted-attention context, learners who retained relatively higher attentional resources tended to exhibit more extensive gaze-based exploration.

This pattern suggests a compensatory mechanism: when task difficulty depletes attentional capacity across the cohort, learners with preserved (relative) resources redirect their search effort toward more thorough visual exploration to compensate for degraded

cognitive focus. The reversal does not indicate that higher absolute attention predicts exploration; rather, it reflects how the same cognitive resource (attention) is allocated differently under distinct difficulty contexts.

This finding aligns with the CAMIL model's prediction that high cognitive demands amplify performance heterogeneity [1] and underscores the critical risk of misclassifying learner cognitive states when behavioral indicators are interpreted without considering concurrent difficulty level and attentional availability [5].

5.3 Implications, Limitations, and Conclusion

These findings carry direct implications for adaptive XR learning system design. Because the same behavioral signal carries different cognitive meanings across difficulty levels and attentional states, real-time learner state monitoring requires multimodal data that combines objective behavioral indicators (gaze, head movement) with subjective attention measures and explicit difficulty-level context. A learner exhibiting simultaneously low attention and high gaze exploration under peak demand may not be "strategic" but rather "compensatory"—attempting to maintain performance through expanded search despite depleted attentional capacity. Conversely, low exploration coupled with low attention under high demand may indicate cognitive overload and risk of disengagement, warranting targeted adaptive scaffolding.

Several limitations should be noted. The small sample size limits generalizability, and the modest strength of the attention–exploration relationship suggests substantial individual variability. The fixed task order, while ecologically valid, introduces potential order and fatigue effects. Future research should employ larger, multisite samples to confirm the replicability of the difficulty-contingent reversal, examine how these behavioral-attentional profiles relate to diagnostic accuracy outcomes, and investigate whether real-time multimodal monitoring can support adaptive difficulty adjustment in clinical XR training.

This study has several limitations. The modest sample size (n = 21) limits generalizability, though the consistent direction of effects across multiple indicators warrants larger-scale replication. The fixed task order, retained for ecological validity in line with standard clinical workflow, cannot fully separate difficulty effects from order or fatigue effects; counterbalanced designs are needed where clinically feasible. Self-reported attention, collected post-task, may not capture moment-to-moment fluctuations; future research should incorporate diverse cognitive load measures (e.g., pupillometry, EEG) to formally test the behavioral compensation hypothesis. Finally, future work should examine how these multimodal behavioral signatures predict diagnostic accuracy to validate their utility as adaptive assessment tools in XR training

In conclusion, this study provides empirical evidence that task difficulty produces divergent, difficulty-dependent trajectories in attention and exploratory behavior in XR. Critically, the functional meaning of behavioral indicators (gaze, head movement) is not static but context-dependent, shaped by both difficulty level and the learner's residual attentional capacity. These findings advance the theoretical understanding of learner cognitive states in immersive environments and offer a nuanced behavioral basis for designing more responsive, context-aware clinical training systems that account for the complex interplay between objective exploration and subjective attentional availability.

Do Online Quiz-Taking Behaviors Matter? An Event-Level Log Analysis in Computer Science Courses

Steve Geinitz
Metropolitan State University of Denver
geinitz@msudenver.edu

ABSTRACT

This work-in-progress study asks whether fine-grained online quiz process data can explain exam performance in computer science courses. Using event logs from two courses, we aggregated quiz behavior for $N = 138$ student-exam observations and investigated whether browser focus-switching ("page blur") and broader quiz-taking profiles added explanatory value beyond pre-semester GPA. We extracted ten behavioral features capturing blur frequency, timing, attempts, variability, and formative quiz performance, then applied random-forest feature ranking, hierarchical regression, and K-means clustering. Page blur frequency emerged as the strongest behavioral predictor and was found to be statistically significant in predicting summative exam performance beyond pre-semester GPA alone ($p = 0.041$). In contrast, interpretable behavioral clusters did not significantly improve model fit ($p = 0.148$). The results suggest that a specific attention-related process signal can be more informative than broader behavioral profiles, although its gain over an academic baseline is modest. These findings are used to motivate a future intervention in which page blur is embedded within a broader Effort-and-Engagement score is shared with students through personalized feedback.

Keywords

student assessment, learning management systems, learning analytics, process data, nudge interventions

1. INTRODUCTION

Online quizzes are now routine in education but are often observed only through scores. In unproctored settings, that leaves instructors with little visibility into how students interact with an assessment and whether they persevere with a challenging problem, switch away to another resource, or engage in repeated practice. Learning analytics makes these behaviors visible through learning management system (LMS) process data, but it remains unclear which signals are genuinely useful for explaining later summative performance.

That question is especially important when quizzes function as low-stakes, frequent assessments rather than one-shot checkpoints. In that setting, quiz logs capture not only performance but repeated opportunities for practice, retakes, and feedback before a higher-stakes exam. This makes them a useful context for analytics intended to support students early, while there is still time for behavior change.

The work herein focuses on one concrete signal: browser focus loss during a quiz attempt, recorded as a "page blur." We treat blur events as a low-cost, imperfect proxy for attention switching or external resource use. The study is also part of a broader work-in-progress effort to develop an Effort-and-Engagement (EE) score that combines quiz behaviors with other student-facing course indicators to support non-punitive, personalized feedback. Here, however, we narrow the contribution to two questions.

- **RQ1:** Does the frequency of browser focus-switching ("page blur" events) during quizzes predict final exam performance, after controlling for students' baseline academic ability (GPA)?
- **RQ2:** Can unsupervised clustering of quiz behaviors (including timing, attempts, and blurs) identify distinct student profiles that explain performance differences better than GPA alone?

2. RELATED WORK

Process-data research shows that event logs can reveal strategies that are not visible in correctness-only measures [7, 8]. In LMS settings, log event features can predict achievement, but recent reviews emphasize that these gains depend heavily on feature engineering, context, and strong baseline comparison [1, 13]. Process-mining and formative-assessment studies have also shown that quiz behavior can be summarized into interpretable patterns or clusters [2, 4, 9].

Attention and multitasking research provides the conceptual motivation for using page blur as a signal. Attention can be inferred from interaction traces [18], off-screen exam behaviors can be detected through more intrusive sensing [5], and multitasking is often associated with poorer academic outcomes [10, 12, 17]. At the same time, window-switching behaviors are context dependent and should not be treated as a standalone cheating detector or risk label [14, 16]. This tension motivates our focus on whether a specific blur signal is more useful than broader behavioral profiling.

3. METHODS

We analyzed quiz logs from the Canvas LMS for two upper-division computer science courses offered during Fall 2025. To align quiz behavior with major assessments, we aggregated data over two eight-week windows. Namely, quizzes preceding the midterm and quizzes preceding the final. Because students could contribute to one or both windows, the final dataset contained $N = 138$ student-exam observations from roughly 70 students. The outcome variable was the corresponding exam grade, with pre-semester GPA serving as the academic baseline. Many quizzes included randomized Canvas "Formula" items, which reduced the value of answer memorization across attempts and made repeated attempts more interpretable as continued engagement with the procedure.

For each observation, we extracted ten quiz-level features describing blur frequency and change, time on task, timing variability, number of attempts, days of engagement, and formative quiz performance. We first trained a random forest model to identify the most salient behavioral predictors, then estimated hierarchical linear models to compare a GPA-only baseline with a GPA+blur model and a GPA+cluster model. For clustering, we tested $K = 2$ through $K = 5$ on the full behavioral feature set and retained $K = 3$ because it yielded the most interpretable profiles. We also used 5-fold cross-validation as a secondary comparison between blur-based and cluster-based predictive configurations. The extracted features were:

- **avg_page_blurred_mean**: average page-blur frequency per attempt
- **avg_blurred_change_mean**: average change in blur count across attempts
- **avg_days_between_attempts_mean**: average spacing between attempts
- **avg_duration_mean**: average attempt duration
- **avg_duration_change_mean**: average change in duration across attempts
- **pct_correct_mean**: mean highest formative quiz score
- **std_duration_mean**: within-quiz duration variability
- **distinct_days_mean**: average number of active quiz days
- **std_page_blurred_mean**: variability in blur frequency
- **total_attempts_mean**: average number of quiz attempts

Note that many of those features consist of a summary statistic, e.g. average, over all the attempts for one quiz. These are then averaged again over all of the quizzes in the time period using an arithmetic mean to yield one feature for each student-exam pair.

4. RESULTS

The random-forest feature ranking identified GPA as the strongest overall predictor, but page-blur measures emerged as the most important behavioral features, with

Table 1: Top Behavioral Features from the Random Forest

Feature	Importance
`avg_page_blurred_mean`	0.155
`avg_blurred_change_mean`	0.111
`avg_days_between_attempts_mean`	0.077
`avg_duration_mean`	0.069
`avg_duration_change_mean`	0.067

`avg_page_blurred_mean` and `avg_blurred_change_mean` ranking above formative quiz performance. We therefore centered the confirmatory models on `avg_page_blurred_mean`.

For RQ1, the GPA-only model explained 18.2% of the variance in exam grades ($R^2 = 0.182$). Adding average blur frequency increased R^2 to 0.207, and the blur coefficient was negative and statistically significant ($\beta = -0.512$, $t = -2.063$, $p = 0.041$). The nested-model comparison was also significant ($F_{1,135} = 4.26$, $p = 0.041$). In practical terms, students who switched away from the quiz window more frequently tended to perform worse on the associated summative exam, even after accounting for GPA.

For RQ2, K-means with $K = 3$ yielded interpretable profiles that we summarized as steady workers, high-effort retrying students, and low-effort/high-distraction students. However, adding these cluster labels to the GPA model did not significantly improve model fit ($R^2 = 0.205$; $F_{2,134} = 1.94$, $p = 0.148$). This same pattern appeared in cross-validation also, as seen in Table 2, where models using the continuous blur feature outperformed those using cluster labels. Together, these findings suggest that a granular, theoretically motivated attention signal carried more explanatory value than broader behavioral categories.

The three clusters were still descriptively useful. The "steady worker" profile paired longer, more focused attempts with strong quiz scores; the "high-effort retrying" profile showed repeated, shorter, focused attempts; and the "low-effort/high-distraction" profile combined fewer attempts with more blur events and weaker formative performance. These profiles suggest meaningful differences in quiz-taking strategy, even though they did not explain summative performance beyond GPA.

- **Steady workers**: longer attempts, moderate retake behavior, and relatively low blur frequency
- **High-effort retrying students**: more attempts spread across days, shorter attempts, and strong formative scores
- **Low-effort/high-distraction students**: fewer attempts, less distributed engagement, and the highest blur frequency

Table 2 shows the comparison of blur-based and cluster-based models using 5-fold cross-validation. The same pattern holds there, in which models using the continuous blur feature achieved lower error than those using cluster labels, with the random forest with GPA and blur performing best

Table 2: 5-Fold Cross-Validation Comparison

Model	RMSE
Random Forest (GPA + Blur)	18.08
Linear Regression (GPA + Blur)	18.53
Random Forest (GPA + Clusters)	18.55
Linear Regression (GPA + Clusters)	18.71

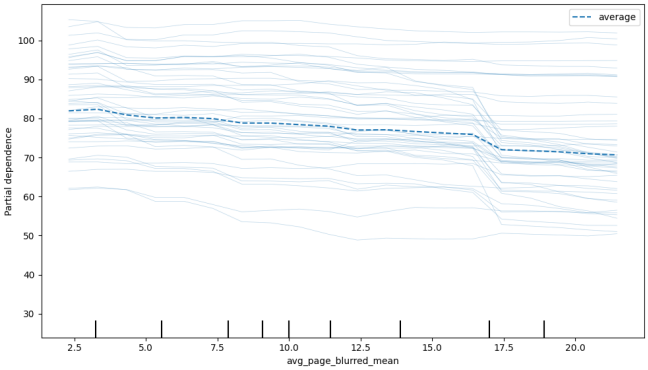

Figure 1: Partial dependence and ICE plot for average page blur frequency and its relationship with exam scores. As blur frequency increases, the modest but statistically significant negative relationship can be seen.

overall. Figure 1 presents the partial dependence and individual conditional expectation plot when average page blurs were used to directly predict exam performance.

5. DISCUSSION AND NEXT STEPS

The central finding is that granularity matters. Namely, that a specific, theoretically grounded signal tied to attention switching explained more than broad behavioral profiles. This does not mean that page blur should be treated as a direct proxy for cheating or disengagement. The gain beyond GPA was modest, and prior work shows that log metrics are highly context dependent [1, 14]. Still, blur frequency appears useful as a low-stakes risk signal when it is interpreted alongside other course behaviors rather than in isolation.

This is also why the clustering result remains useful, even though it was not significant in the regression model. The clusters helped describe different quiz-taking strategies in a way that may still matter for instructor insights and feedback. In other words, the profiles were descriptively interesting, but the blur metric was the sharper explanatory signal for this dataset. However, the implication should not be that blur events replace broader views of student engagement. But, instead, that they can add a specific attention-related signal that is easy to collect and interpret. In practice, this makes blur events more useful as one component of a larger engagement model than as a standalone indicator.

That framing directly informs our next step. We are using this result to design an Effort-and-Engagement (EE) score that combines page blur frequency with broader indicators such as attendance, assignment completion, quiz participation, and retakes. The aim is not high-stakes classification, but student-facing feedback that makes engagement patterns more visible and actionable. This direction is consistent with work on nudge analytics [3], student-facing dashboard feedback [6, 19], and personalized nudges [15]. In future work, we plan to evaluate whether periodic, supportive EE updates can shift quiz behavior, quiz-retake patterns, and student perceptions of support without becoming punitive or noisy. That future study will let us test whether a small but interpretable log-data signal can be translated into an actionable, student-facing intervention rather than remaining only a predictive model.

5.1 Limitations

Several limitations matter for interpreting the current result. First, this is an observational analysis from two upper-division computer science courses at a single institution. The dataset is adequate for this work-in-progress, but it is modest, and the student-exam structure means that some students contributed more than one observation across the two assessment windows. The findings should therefore be interpreted as evidence of a promising signal in a specific course context rather than as a general effect size for LMS quizzes.

Second, blur events are behaviorally ambiguous. A page blur can reflect off-task multitasking or answer-seeking, but it can also reflect note-checking, calculator use, accessibility needs, temporary interruptions, or ordinary course-related resource use. Our claim is deliberately narrower, which is that frequent focus-switching is associated with lower exam performance after controlling for GPA. We do not interpret blur as a direct measure of cheating, intent, or disengagement. That is also why we frame the signal as low stakes and combine it with other student-controllable behaviors in the planned intervention.

Third, the predictive gain is modest. GPA remained the strongest baseline predictor, and the increase in explanatory power from adding blur was meaningful but not large. For practice, that means the value of process data here is not that it unlocks a highly accurate predictive model. Its value is that it surfaces a concrete, interpretable behavior that instructors can discuss with students and potentially target through supportive feedback. That practical value is stronger in courses that already rely on low-stakes, frequent quizzes. Repeated formative assessments create multiple chances to practice, revisit material, and act on feedback, so they also create multiple opportunities for instructors to notice process patterns before a major exam. This is one reason the signal is more useful for early support than for high-stakes classification.

5.2 Intervention Design

The planned EE score aggregates five student-controllable dimensions of course engagement:

1. **Attendance**: proportion of class sessions attended
2. **Assignments**: proportion of assignments turned in
3. **Quiz attempts**: proportion of available quizzes attempted
4. **Quiz retakes**: repeated engagement with formative quizzes
5. **Page blur frequency**: average focus-switching rate during quiz attempts

The score is intended to surface interpretable components rather than produce a single opaque risk label. The sample

message below illustrates the style of the planned feedback, which aims to be supportive, behavior-focused, and framed around concrete next steps, rather than to shame or punish.

Your Effort & Engagement Update

Hi [Student],

Here is your current effort-and-engagement snapshot for CS 1234. This is not a grade—it is a reflection of how you have been engaging with the course so far.

Attendance	85%	
Assignments Submitted	90%	
Quizzes Attempted	100%	
Quiz Retakes	40%	
Quiz Focus (blur rate)	65%	
Overall EE Score	**71/100**	(class mean = 75)

You are doing well—you have attempted every quiz and your attendance is strong. Two areas to consider: you have retaken fewer quizzes than most of your peers, and your quiz focus score suggests you may be switching away from the quiz window frequently. Retaking quizzes can help you practice the process, and staying on-task can make that practice more valuable.

Keep it up!

Figure 2: Representative EE score message used to illustrate the planned student-facing intervention.

The design of these messages follows three principles from prior work. They should be 1) *personalized* to the student's own data, 2) *explanatory* about which behaviors are driving the score, and 3) *actionable* in the next steps they recommend [6, 11, 19]. The LLM should itself be viewed as an auxiliary delivery mechanism for that feedback, rather than as the source of the intervention logic itself.

We envision these messages being delivered routinely, but are aware students may ignore them if frequency is too high. Ideally, the message supports reflection without becoming part of the grading environment. Each EE score component is transparent and controllable, allowing students to see if their score is affected by attendance, missing assignments, limited quiz participation, low retake behavior, or frequent focus-switching. This transparency is important as the intervention aims to prompt helpful self-regulation rather than create a vague sense of surveillance.

The next study will therefore focus less on prediction and more on response to feedback. We plan to examine whether supportive EE updates change behaviors that instructors actually want to influence, such as quiz completion, retake use, and sustained on-task engagement, and whether students perceive the messages as useful, fair, and non-punitive. That evaluation is necessary before any broader deployment, because even interpretable analytics can fail if the feedback they generate is mistimed, noisy, or too easy to misread.

6. CONCLUSION

The main contribution of this work has been to investigate several quiz-process indicators and has found that page blur frequency provides the clearest behavioral signal beyond GPA. While broader student profiles can be useful for classifying students broadly, their prediction capabilities are more limited. The combination of modest predictive value and high interpretability makes blur most promising as one component of a student-facing engagement intervention rather than as a standalone risk flag. Because the signal comes from low-stakes, frequent quizzes, it is also available early enough to inform supportive feedback before higher-stakes assessments occur.

7. ACKNOWLEDGEMENTS

This research was approved by, and conducted in compliance with, the Institutional Review Board (IRB) at Metropolitan State University of Denver. The authors would like to express their gratitude to the Human Subjects Protection Program for their guidance and support in ensuring the ethical integrity of this study. ABSTRACT

Large language models are increasingly used in math learning settings for hint generation, worked–solution support, and automated assessment. In multilingual deployment, however, prompt choice affects not only correctness but also response cost and fairness across learner languages. We study three prompting paradigms, Direct, Chain–of–Thought (CoT), and Program–of–Thought (PoT), across English, German, French, and Luxembourgish on three math benchmarks spanning school to college levels. Using Qwen3–32B, we compare accuracy, token usage, and latency with and without self–consistency. We find that CoT with self–consistency is the strongest default on arithmetic tasks, while PoT with self–consistency becomes more effective on harder problems requiring sustained computation. Across settings, we observe a stable performance hierarchy of EN $>$ DE $\approx$ FR $>$ LB, with LB also incurring the largest token and latency overhead. These results show that prompt configuration is a practical design decision for multilingual math support systems, with direct implications for reliability, efficiency, and cross–lingual fairness.

1. INTRODUCTION

Large language models (LLMs) are increasingly integrated into educational mathematics workflows, including hint generation, worked–solution support, answer validation, and teacher–facing verification. In multilingual settings, such systems must provide support that is not only accurate, but also timely, interpretable, and equitable across learner languages. Yet prompt design is often treated as a purely technical implementation choice, even though it directly affects the quality, transparency, cost, and latency of learner–facing support [6, 18].

Prior work shows that prompting strategies such as Chain–of–Thought (CoT), self–consistency, and Program–of–Thought (PoT) can substantially affect mathematical reasoning performance [20, 19, 2, 4]. CoT elicits intermediate reasoning steps before the final answer, which can improve solution quality and make the response more interpretable. Self–consistency improves robustness by aggregating multiple sampled solutions through voting, although it also increases token usage and latency [19]. Program–based approaches such as PoT or PAL delegate numerical computation to executable code, which is often beneficial on harder mathematical problems that require sustained symbolic or numerical manipulation [2, 4]. These strategies therefore differ not only in correctness, but also in cost, response time, and pedagogical transparency.

Educational research has also begun to explore LLMs as components of tutoring, explanation generation, automated feedback, and assessment workflows [21, 1, 24]. In such settings, evaluation must go beyond raw correctness. A system that is accurate but slow may be unsuitable for interactive classroom use, while a system that produces correct but opaque answers may be less useful for learning support than one that provides interpretable intermediate reasoning. In multilingual educational deployment, these trade–offs become even more important because differences in response quality or speed across languages can translate into unequal learner support.

Multilingual mathematical reasoning remains uneven across languages. Benchmarks such as MGSM show that LLMs can solve math problems in multiple languages, but performance often degrades outside English and other high–resource settings [14]. More recent work similarly reports sensitivity to language resource level, translation quality, and prompting setup [12, 15]. Recent work also questions whether single–set math benchmark accuracy is sufficient for evaluating reasoning, showing that LLM performance can vary across controlled re–instantiations of the same GSM8K–style problems and can deteriorate when irrelevant but seemingly relevant clauses are added [10].

These issues are especially relevant for lower–resource languages, where weaker pretraining coverage may affect both answer quality and reasoning stability. However, prior work

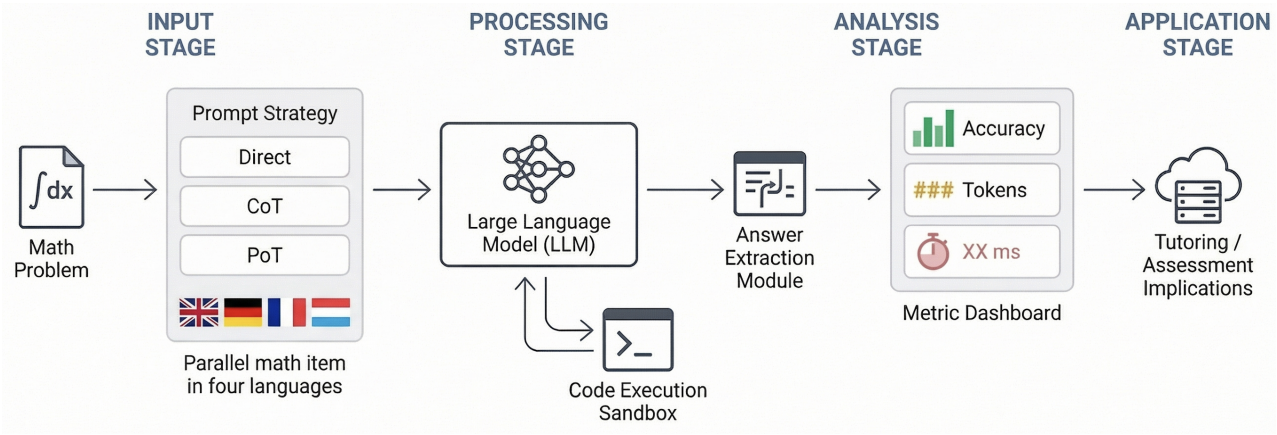

Figure 1: Pipeline of multilingual math support evaluation.

has focused mainly on per–language accuracy and has paid less attention to how prompt choice changes the trade–offs among correctness, token cost, latency, and interpretability in multilingual educational use.

These benchmarks are not only abstract tests of model reasoning. They also approximate common functions in learner–facing systems. Arithmetic problems are closely related to stepwise hinting, answer checking, and formative support in school mathematics, while harder problems reflect advanced feedback, verification, and teacher–facing solution analysis. Under this view, prompt choice is not merely an inference–time optimization detail. It changes the quality, speed, and interpretability of support that multilingual tutoring and assessment systems provide to different learner groups.

We address this gap through a compact empirical study across four languages, English (EN), German (DE), French (FR), and Luxembourgish (LB), using three prompting paradigms: Direct, CoT, and PoT. We evaluate performance on arithmetic and harder mathematics benchmarks and analyze both answer quality and computational cost, with particular attention to LB as a low–resource language relevant to multilingual educational deployment.

These trade–offs matter directly for educational use. In tutoring and hint generation, prompt choice affects whether learners receive interpretable step–by–step guidance or only a final answer. In automated checking, latency and computational cost affect classroom usability and scalability. In multilingual settings, unequal performance across languages raises fairness concerns because students using lower–resource languages may receive slower or less reliable support. Our study therefore treats prompting as a design choice for multilingual tutoring, feedback, and assessment systems, not only as an inference–time optimization problem. Our contributions are:

- We provide a focused evaluation of multilingual math support performance across EN, DE, FR, and LB, including a low–resource language.
- We show that the most suitable prompting strategy depends on task difficulty. CoT with self–consistency is strongest on arithmetic tasks, while PoT with self– consistency is more effective on harder mathematics.
- We show that lower–resource language support can be both less accurate and more computationally expensive, which makes prompt configuration a fairness and deployment issue for tutoring and assessment systems.

2. METHODOLOGY

2.1 Benchmarks and languages

We evaluate on three math benchmarks covering different difficulty levels: GSM8K [3], SVAMP [11], and CollegeMath [16]. GSM8K and SVAMP emphasize arithmetic word problems, while CollegeMath contains advanced textbook–style mathematics. We use EN test sets and translate them into DE, FR, and LB using DeepL, preserving mathematical expressions verbatim and applying light post–editing. Manual spot–checking was used to verify that translated items preserved problem structure, numerical references, and solution equivalence across languages. This step helps reduce the risk that observed cross–lingual differences are caused by obvious translation artifacts rather than by differences in model behavior. Table 1 shows a parallel SVAMP item with the original EN problem and its FR, DE, and LB translations.

These benchmarks also serve as controlled proxies for multilingual educational use cases, including hint generation, worked–solution support, answer validation, and teacher–facing checking or verification. To support reproducibility and facilitate further experimentation, the translated benchmark files as well as the full code used for the evaluation pipeline are publicly available on the accompanying repository[1].

2.2 Model and prompting

We use Qwen3–32B [22], a strong multilingual open–weight model with established mathematical reasoning ability, making it suitable for controlled comparison across prompt styles and languages. It is a 32B dense model trained on approximately 36T tokens across 119 languages and dialects, and

[1]Project repository: multilingual-math-bench.

Table 1: Parallel SVAMP example with the original English item and its French, German, and Luxembourgish translations.

Lang.	Problem text
EN	Debby bought 200 water bottles and 256 soda bottles when they were on sale. If she drank 312 water bottles and 4 soda bottles a day, how many days would the soda bottles last?
FR	Debby a acheté 200 bouteilles d'eau et 256 bouteilles de soda lorsqu'elles étaient en promotion. Si elle buvait 312 bouteilles d'eau et 4 bouteilles de soda par jour, combien de jours les bouteilles de soda dureraient–elles ?
DE	Debby hat 200 Wasserflaschen und 256 Limonadenflaschen gekauft, als diese im Angebot waren. Wenn sie täglich 312 Wasserflaschen und 4 Limonadenflaschen trinkt, wie viele Tage reichen die Limonadenflaschen dann?
LB	Debby huet 200 Waasserfläschen a 256 Soda–Fläschen kaaft, wéi se am Rabatt waren. Wann si all Dag 312 Waasserfläschen a 4 Soda–Fläschen drénkt, wéi vill Deeg géifen d'Soda–Fläschen duergoen?

includes a native thinking mode for internal reasoning [22]. We evaluate it across three benchmarks, four languages, and three prompting strategies in a multilingual math–support setting. Figure 1 summarizes the evaluation pipeline.

For each problem, we compare three prompting modes. Direct prompting requests only the final answer. CoT prompting elicits intermediate reasoning steps before the answer. PoT prompting generates executable Python code whose returned output is treated as the final answer. For each strategy, we evaluate both single–sample decoding and self–consistency with five samples (SC@5). In the SC@5 setting, we sample five independent outputs per item and aggregate their final answers by majority vote. This design allows us to compare not only prompting styles, but also the trade–off between single–pass efficiency and ensemble–style robustness.

2.3 Decoding and evaluation

We use the same prompting setup across all four languages and evaluate both single–sample decoding and self–consistency with five samples (SC@5). We use a fixed temperature of $T = 1.0$ across prompting strategies to encourage output diversity for self–consistency, while leaving other decoding parameters at their default settings.

For each dataset and language, we evaluate the full test split under both single–sample and SC@5 settings. For each item, final answers are extracted with a uniform post–processing pipeline that normalizes formatting differences across languages and prompting styles. Predictions are counted as correct when the extracted answer matches the reference after simple normalization, such as removing whitespace or formatting wrappers. For arithmetic expressions, we additionally allow equivalence under basic symbolic normalization. For PoT, only the printed final output is evaluated, and executions that fail to produce a parsable answer are counted as incorrect. We record problem–level accuracy, average generated tokens, and wall–clock latency. This setup allows us to compare not only answer quality, but also the deployment trade–off between efficiency and robustness in multilingual educational settings.

We report problem–level accuracy, average generated tokens, and wall–clock latency. These metrics are relevant for multilingual educational deployment, where systems must balance answer quality with response cost and speed. Accuracy captures answer quality, generated tokens approximate inference cost, and latency reflects whether feedback can be delivered quickly enough for interactive use.

3. RESULTS AND DISCUSSION

Table 2 summarizes the main accuracy patterns. Across prompting modes and datasets, self–consistency generally improves over single–sample decoding, with larger gains on harder tasks and for some prompting styles. Two findings stand out. First, the best prompting strategy depends on task difficulty: CoT with self–consistency is strongest on arithmetic tasks, while PoT with self–consistency becomes the best–performing option on harder mathematics. Second, performance is consistently uneven across languages: EN performs best, DE and FR are usually close behind, and LB shows the largest degradation.

Table 2: Accuracy (%) for Qwen3–32B across languages. Highlighted rows indicate the best–performing method.

Dataset	Method	EN	DE	FR	LB
GSM8K	Direct	78.1	64.8	66.9	33.5
	CoT SC@5	**87.5**	**71.2**	**69.1**	**51.5**
	PoT SC@5	69.3	70.3	68.5	44.7
SVAMP	Direct	81.6	72.2	74.3	44.2
	CoT SC@5	**87.0**	**76.9**	**74.9**	**68.6**
	PoT SC@5	66.2	73.9	71.9	64.6
CollegeMath	Direct	41.6	41.0	38.4	31.1
	CoT SC@5	38.2	40.0	39.9	35.6
	PoT SC@5	**56.6**	**48.7**	**51.9**	**42.1**

For school–level arithmetic, CoT with self–consistency offers the best balance of performance and interpretability. On GSM8K, for example, CoT SC@5 improves EN accuracy from 78.1% with Direct prompting to 87.5%, and similar gains appear on SVAMP. This pattern is consistent with prior work showing that self–consistent CoT can recover diverse but correct reasoning paths [19]. For learner–facing support, CoT offers an additional advantage: beyond improving answer quality, it produces explicit intermediate reasoning that can be repurposed as hints or worked examples.

PoT behaves differently on easier benchmarks. On GSM8K for Qwen3–32B, PoT can underperform because the model sometimes fails to follow the Python instructions or produces code with syntax errors, which the execution environment counts as incorrect. This suggests that the underlying solution strategy may be reasonable, but brittle at the implementation level, in line with prior observations for PAL and related code–based methods [2, 7].

A qualitative inspection of failed outputs suggests that er-

Table 3: Observed trade–offs of prompting strategies for multilingual math support.

Method	Observed strength	Observed constraint	Deployment relevance
Direct	Computationally efficient and structurally simple.	Does not provide explicit intermediate reasoning.	Appropriate when answer delivery and low overhead are prioritized.
CoT + SC@5	Strongest arithmetic performance, with interpretable reasoning traces.	Increased token usage and response latency.	Appropriate for explanatory support, including hints and worked examples.
PoT + SC@5	Strongest performance on harder tasks requiring sustained computation.	Depends on stable code generation and execution.	Appropriate for advanced verification and more formal solution support.

rors arise from several sources. For Direct and CoT prompting, failures often involve incorrect arithmetic, incomplete final–answer extraction, or reasoning paths that are plausible but numerically inconsistent. For PoT, errors are more implementation–sensitive: some outputs contain syntactically invalid Python code, missing print statements, or code that computes an intermediate quantity rather than the requested final answer. In the translated settings, some failures also appear to be linked to language–specific phrasing or answer–format variation. These observations are not intended as a full causal error taxonomy, but they indicate that multilingual math–support failures involve both reasoning errors and interface–level issues such as parsing, translation, and code execution.

On harder problems, the pattern changes. For CollegeMath, PoT SC@5 outperforms Direct and CoT in EN and remains strongest in the other languages. This suggests that delegating computation to executable code becomes useful when tasks require sustained symbolic or numerical manipulation, in line with prior work on program–aided mathematical reasoning [2, 4]. In educational settings, this makes PoT suited to advanced support scenarios such as automated checking, teacher–facing verification tools, or systems that generate formal worked solutions for difficult exercises.

Table 3 summarizes these observed trade–offs and links each prompting strategy to its most relevant educational deployment scenario.

No single prompting strategy is optimal across all forms of math support. CoT is strongest when interpretable step–by–step guidance is valuable, whereas PoT becomes preferable when computational precision dominates. This matters for educational applications, where the same system is expected to support both hint generation and answer validation.

For educational applications, this distinction is consequential. If a system is primarily used to generate hints or worked examples, CoT may be preferable because it exposes intermediate reasoning that can be shown to learners or adapted by teachers. If the system is used for automated checking or higher–stakes verification, PoT may be preferable on harder tasks because computational reliability becomes more important than explanatory detail. In multilingual settings, these design choices also interact with equity, since learners using lower–resource languages may receive support that differs not only in quality but also in responsiveness.

Across all settings we observe a consistent hierarchy

$$\text{EN} > \text{DE} \approx \text{FR} > \text{LB},$$

where German and French typically retain much of the English baseline, while Luxembourgish shows larger drops, especially on the harder benchmark. This pattern aligns with multilingual math evaluations that report stronger performance for high–resource languages and larger degradation for lower–resource ones [14, 15, 12].

Efficiency also differs by language. Figure 2 shows that LB requires more generated tokens than EN across prompting strategies, with especially large increases under self–consistency. The token gap is also consistent across methods, which suggests that the efficiency disadvantage is not tied to a single prompting style. In our runs, this also translated into higher latency. For example, under single–sample CoT on GSM8K, average latency increased from approximately 5.7 seconds in EN to 7.6 seconds in LB. Thus, lower–resource language support is disadvantaged twice: it is often less accurate and more expensive, which aligns with prior multilingual mathematical reasoning studies reporting stronger performance in high–resource languages and larger drops in lower–resource settings [14, 12, 15]. For multilingual tutoring or classroom–facing systems, this matters because learners using lower–resource languages may receive slower and less reliable support, even when the underlying task is the same.

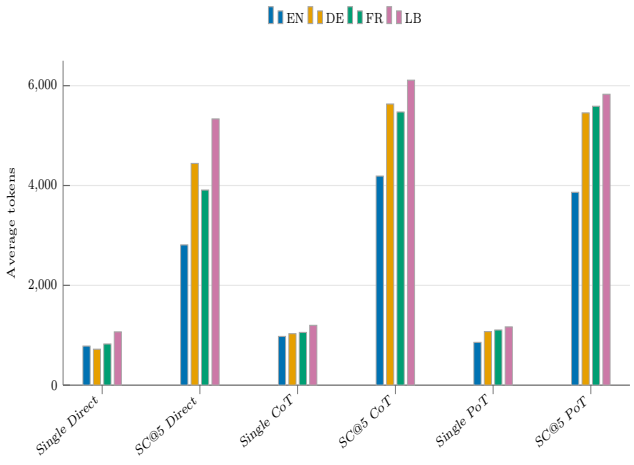

Figure 2: Average token usage across prompting strategies and languages. Self–consistency (SC@5) increases token cost, and LB is consistently among the most expensive settings.

Our findings have three implications for educational data mining and multilingual math support systems: **First**, prompt choice should be treated as a deployment decision rather than a neutral implementation detail. For arithmetic tutoring, CoT with self–consistency provides a strong default because it improves accuracy while preserving interpretable reasoning traces that can support hints, worked examples, or feedback generation [9]. By contrast, Direct prompting may be cheaper, but it offers less transparency and may therefore be less suitable when the instructional goal is to help learners understand the solution process rather than only obtain the correct answer. In education, the value of a response depends not only on correctness but also on whether the reasoning process is understandable and usable. This makes interpretability a functional requirement rather than an optional property when the system is intended to support learning rather than only scoring.

Second, the best strategy changes with task difficulty. For harder mathematics, PoT with self–consistency becomes more reliable than CoT, suggesting that external code execution can stabilize multi–step symbolic or numerical reasoning [23, 8]. This is especially relevant for advanced exercises, automated checking, or teacher–facing systems that must verify mathematically precise solution procedures. In other words, a single prompting strategy is unlikely to be optimal across all educational uses of LLM–based math support.

Third, multilingual support shows clear operational disparities across languages. The consistent hierarchy EN $>$ DE $\approx$ FR $>$ LB indicates that a single prompt configuration may offer uneven quality across learner languages, although this study does not isolate the causal source of the gap. The higher token and latency burden for LB suggests that multilingual systems should use language–specific calibration and fairness auditing rather than assuming uniform performance [5, 17].

This cross–lingual gap has consequences for multilingual educational deployment. A student asking for support in a lower–resource language may receive feedback that is not only less accurate, but also slower and more expensive to generate. This creates an equity issue for tutoring and assessment systems serving linguistically diverse learners. Multilingual math support should therefore be evaluated not only for average correctness, but also for consistency of support quality across learner languages, alongside broader trade–offs between reasoning quality and computational efficiency [13].

4. LIMITATIONS AND CONCLUSION

This study is benchmark–based and does not evaluate learners, teachers, classroom interaction, or learning outcomes directly. The multilingual setup also relies on translated benchmarks, so residual translation or answer–extraction artifacts may affect results, and EN performance may benefit from stronger pretraining coverage or benchmark familiarity. This caution is reinforced by recent work showing that performance on GSM8K–style tasks can vary across controlled re–instantiations and small problem modifications, suggesting that single benchmark scores may not fully capture reasoning robustness [10]. Our scope is also limited to one multilingual model, four languages, and a small set of prompting strategies, so the exact trade–offs may differ for other models or language settings.

Even with these limitations, the main patterns are consistent. CoT with self–consistency is the strongest default for arithmetic support, whereas PoT with self–consistency is more effective for harder problems that benefit from executable reasoning. Across languages, lower–resource settings such as LB show both accuracy degradation and higher efficiency costs. For multilingual math support systems, prompt configuration is therefore a question of reliability, cost, and fairness. More broadly, evaluating multilingual LLMs for mathematics is not only a question of benchmark performance, but also of how reliably and equitably support can be delivered across learner languages.

5. ETHICS STATEMENT

This study does not involve the collection of new human–subject data, learner interaction data, classroom data, or personal information. All experiments are conducted on existing mathematical benchmark datasets and their translated versions. No personally identifiable information is processed, and no participants are recruited. Therefore, the study does not raise human–subject privacy risks. The work is intended as a benchmark–based analysis of multilingual prompting behavior, not as an evaluation of individual learners or teachers. Because no new human–subject data were collected, local ethics–board approval was not required under the scope of this study.

6. ACKNOWLEDGMENTS

This research was conducted in the context of the LuxVoice project, funded by the Luxembourg National Research Fund (FNR) under grant agreement (project reference 19205922). LuxVoice aims to advance Luxembourgish language technologies and support the development of robust multilingual AI resources. The authors gratefully acknowledge the support of RTL Lëtzebuerg and the University of Luxembourg. This work contributes to broader efforts toward inclusive, reliable, and linguistically grounded AI systems for Luxembourgish and other low–resource language settings.

ABSTRACT

In-app assessments are increasingly used by EdTech programs to measure students' proficiency and guide instructional decisions. Student engagement in these assessments is crucial for generating reliable learning signals; however, efforts to increase student engagement in platform-based assessments often impose additional demands on teachers. To explore an optimal assessment design, we implemented supervised assessments in which a teacher is present while students complete the assessment. We find that supervised assessments significantly increase student engagement, as evidenced by longer average assessment durations and a substantial reduction in timed-out or aborted sessions. At the same time, the number of classes participating in the assessment decreases slightly. These findings highlight a trade-off between assessment quality and participation rates, and suggest that supervision improves data quality primarily through increased student engagement.

Keywords

In-app assessment, Supervised assessment, Student proficiency, Low- and middle-income countries

1. INTRODUCTION

Assessment results constitute a key source of information for understanding the evolution of students' learning. Students and their families respond to feedback and information generated by reliable assessments [3, 4, 5].

Assessment data are also critical for teachers, as they provide information on students' learning trajectories and can inform instructional practices. A growing body of literature examines how teachers use assessment data to guide pedagogical decisions and improve student learning outcomes [10, 9, 12, 13]. This evidence suggests that increased access to assessment information can improve instructional targeting, goal setting, and teachers' self-efficacy [6]. However, there remains limited empirical evidence on how teachers use data generated by information and communication technology (ICT) systems and how such data shape instructional practices in large-scale educational settings [7].

The usefulness of assessment data depends fundamentally on student engagement during assessment activities [8, 14]. In-platform based environments, disengagement — such as rapid guessing, non-response, or aborted sessions — can generate noisy signals about student proficiency. These issues are especially salient in unsupervised digital assessments that are completed without active teacher oversight. Proctoring offers a potential mechanism to address these challenges by introducing teacher supervision during assessments, thereby increasing student engagement and completion. However, teacher supervision also increases the effort required from teachers, which may discourage participation in more demanding assessment formats. Existing evidence on the benefits of proctoring primarily comes from higher education and focuses largely on cheating behavior in online assessments [15, 2], leaving open questions about its role in shaping engagement and data quality in large-scale primary education systems, particularly in low- and middle-income country contexts.

In this paper, we study the effects of introducing supervised assessments on a national-scale EdTech platform operating in Kenya. In September 2025, the platform tested supervised assessments in place of unsupervised assessments, with teachers proctoring students during assessment administration. This proctoring is mostly observational and similar across students in different classes and schools. Using platform data covering more than 300,000 students across approximately 10,000 schools, we examine how teacher supervision influences student engagement and participation in digital assessments.

2. INTERVENTION

EIDU is a digital education platform operating at scale in Kenya. The platform provides interactive learning content in numeracy and literacy through Android devices, with games-based content units adapted to students' individual learning pace [11, 1].

Prior to September 2025, the platform administered assessments in an unsupervised format, where assessment tasks were automatically launched on the device without active teacher oversight and learners could abort the assessments at any point of time. In September 2025, EIDU introduced and tested a supervised assessment format, in which a teacher is present and actively proctors students as they complete the assessment. During the assessment teachers observe learners without providing any feedback or scaffolding. Examples of digital assessment items of letter recognition and number identification can be found in Figures 1 and 2.

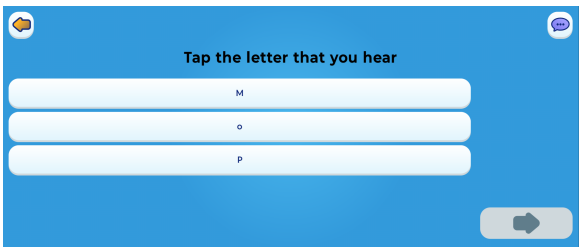

Figure 1: Letter Recognition - Digital assessment

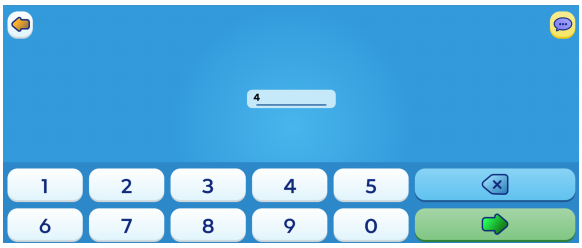

Figure 2: Number identification - Digital assessment

We examine how this introduction of teacher supervision affects student engagement and participation in digital assessments. We measure these outcomes using three school-level indicators: (i) the average time students spent on the assessment; (ii) the share of assessment sessions that were aborted or timed out; and (iii) the average number of classes per school participating in the assessment. These three indicators constitute the main outcome variables of our analysis. We additionally descriptively show how the change from unsupervised to supervised assessments changed the distribution of students' scores.

This large-scale evaluation was conducted in close coordination with county-level education authorities, who approved and monitored the implementation of the intervention. All data were anonymized, and access was restricted to researchers involved in the project.

3. DATA AND METHODS

The data covers the period from January to November 2025 and include 310,363 5-year old learners across 10,322 schools and 25,130 classes. Students are assessed in both Reading and Mathematics, completing 11 items in letter recognition and 12 number identification per assessment moment. All outcomes are aggregated at the school-level.

To examine the effects of supervised assessments, we use a pre-post research design that compares outcomes before and after the introduction of teacher supervision. The pre-intervention period is coded as $t = 0$ and the post-intervention period as $t = 1$. The post period corresponds to the introduction of supervised assessments in September 2025, when supervised assessments were introduced and tested in the platform.

For each school s and time period $t \in \{0, 1\}$, we estimate the following specification:

$$Y_{st} = \alpha + \beta S_t + \varepsilon_{st}, \tag{1}$$

where Y_{st} denotes the outcome of interest and S_t is a dummy variable equal to 1 in the post-intervention period (supervised assessments) and 0 in the pre-intervention period (unsupervised assessments). The coefficient β captures the average change in school-level outcomes following the introduction of teacher supervision. ε_{st} stands for the error term.

4. RESULTS

Tables 1–3 present the main results. In each table, Column (1) reports results for the full sample. Column (2) restricts the sample to one month before and after the introduction of supervised assessments to account for potential learning trajectory effects over time. Column (3) of Table 1 further restricts the sample to completed assessments. In addition, we report the average level for each outcome for unsupervised assessments.

Tables 1 and 2 indicate a higher level of engagement among the students who participated in the assessments. The introduction of supervised assessments is associated with increases in average assessment duration ranging from 0.09 to 0.26 minutes. This corresponds to an increase between 9% and 25% compared with unsupervised assessments. We also find a large reduction in the share of sessions that were aborted or timed out. The latter effect is particularly pronounced, with aborted or timed-out sessions declining by approximately 30 percentage points following the introduction of supervision. These patterns suggest that teacher proctoring substantially increases the likelihood that students remain engaged through assessment completion.

At the same time, supervised assessments are associated with a modest reduction in participation across classes. Table 3 shows that the average number of classes per school participating in assessments declined by approximately 0.3 classes following the introduction of supervision. This result suggests increased selectivity in class participation when assessments are administered under teacher supervision.

The distribution of assessment scores also changes following the introduction of supervision. We compute the share of correct items for each student assessment and then aggre-

Table 1: Effects on Mean duration (in minutes)

R-squared	0.004	0.003	0.007

Notes: The table presents school-level OLS regression results with mean duration as the dependent variable. The omitted category corresponds to non-supervised assessments. Standard errors clustered at the school level are reported in parentheses.*** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

Table 2: Effects on the Share of sessions aborted

	%	
	(1)	(2)
Supervised	-0.346***	-0.330***
	(0.00380)	(0.00430)
Av. Unsupervised	0.61	
1 Month before-after	NO	YES
Observations	16,911	11,647
R-squared	0.331	0.283

Notes: School-level OLS regression results with the share of aborted/timed-out sessions as the dependent variable. Standard errors clustered at the school level are in parentheses.*** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

Table 3: Effects on Number of classes engaged

	Number of classes	
	(1)	(2)
Supervised	-0.293***	-0.272***
	(0.00778)	(0.0113)
Av. Unsupervised	1.23	
1 Month before-after	NO	YES
Observations	16,911	11,647
R-squared	0.034	0.038

Notes: School-level OLS regression results with the number of classes engaged as the dependent variable. Standard errors clustered at the school level are in parentheses.*** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

gate these measures at the school level. As shown in Figure 3, unsupervised assessments exhibit a pronounced mass of scores at zero, indicative of low student engagement and high levels of non-response. In contrast, supervised assessments display a markedly different score distribution, characterized by higher average scores and the absence of zero inflation, consistent with increased participation among participating students. As observed in Table 3, the introduction of supervised assessments led to a decline in the share of classes per school participating in the assessments. To control for this compositional effect, Figure 4 includes only classes that participated in both assessments. The figure shows a similar pattern in the score distributions for supervised and unsupervised assessments.

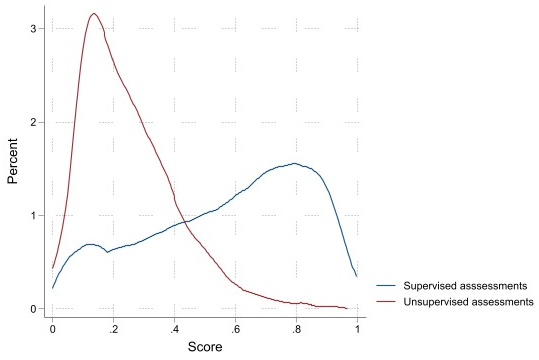

Figure 3: Score distribution, school level (scale: 0–1)

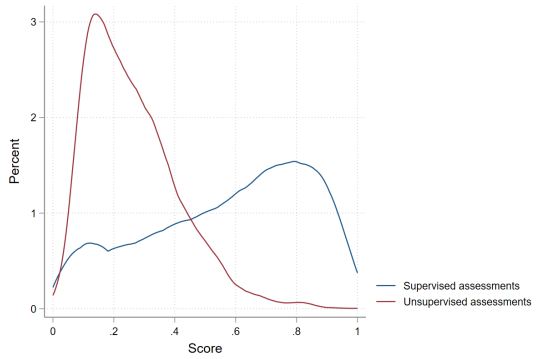

Figure 4: Score distribution for classes observed in supervised and unsupervised assessments, school level (scale: 0–1)

5. CONCLUSION

Accurate student assessment data is key to understanding students' progress and informing instructional decisions across educational contexts. The value of such data depends not only on assessment content, but also on how assessments are administered and the extent to which students are engaged during assessment activities.

As the EdTech sector continues to expand, digital assessments are increasingly embedded alongside instructional materials and used to guide personalization at scale. In this

setting, ensuring meaningful student engagement during assessment becomes critical for generating reliable learning signals. To address this challenge, EIDU introduced supervised assessments, in which teachers proctor students during assessment administration. While supervision has the potential to improve data quality, it also increases the burden on teachers.

Our results show that students engage more with supervised assessments, as measured by the increase in average time spent answering items and the strong decrease in the average share of sessions that were aborted or timed out. However, we also observe a slight decrease in the average number of classes participating in assessment, consistent with increased burden for some teachers. These findings highlight a tradeoff between assessment engagement and participation when supervision is introduced at scale.

Future work should explore in-product solutions that preserve the engagement benefits of supervision while reducing participation-related burden, further enabling the collection of higher-quality digital assessment data.

ABSTRACT

Large language models (LLMs) have shown the potential for generating educational content at scale, assisting educators in creating practice tasks or synthesizing data for training educational models. However, LLMs suffer from the "Artificial Hivemind" effect, where they produce homogeneous content. This homogeneity limits the diversity of LLM-generated tasks, a crucial factor in these educational settings. In this paper, we investigate how to increase the diversity of generated tasks while keeping their utility high. Inspired by the divergent–convergent thinking stages in creativity literature, we propose a prompting framework with two reasoning stages: (1) exploring the creative space, and (2) satisfying the input requirements. We evaluate CreativeDC, a method instantiated from this framework in the domain of Python programming, using both automated metrics and expert evaluation. Results show that CreativeDC produces significantly more distinct high-utility tasks (about 1.6×) than baselines. Our work offers an effective approach for generating and evaluating more diverse tasks at scale.

Keywords

Large Language Models, Task Generation, Programming Education, Diversity, Divergent–Convergent Thinking

1. INTRODUCTION

Large Language Models (LLMs) have demonstrated remarkable capabilities, leading to their rapid adoption across important domains such as education [1–14]. In particular, prior work has used LLMs to generate programming tasks [15–18], enabling active learning strategies such as the "doer effect" through task generation at scale [19, 20]. Moreover, LLMs can also be used to generate synthetic data, for example, for training tutor models [12, 14, 21]. In such settings, maintaining task diversity is crucial to adequately cover learning objectives and different difficulty levels. Yet LLMs have been shown to exhibit an "Artificial Hivemind" effect [22], where they tend to produce similar and repetitive outputs within a single model and across different models, resulting in limited output diversity.

Existing work has proposed various methods to address the limited diversity and homogeneity of LLM outputs. These include fine-tuning through preference optimization with creativity signals [23] and using multi-agent discussion or debate frameworks [24]. However, these approaches are typically designed and evaluated for benchmarks such as creative writing or general instruction following, rather than the structured requirements of educational task generation. Another line of work has incorporated thematic topics and learning concepts as input to LLMs to generate a wide range of tasks, e.g., in programming education [15–17]. However, these efforts do not primarily focus on optimizing for task diversity. This gap motivates our central question: *How can we generate a diverse set of high-utility practice tasks*?

In this work, we tackle this question in the context of programming task generation. Drawing inspiration from the creativity literature and the divergent-convergent thinking stages [25–27], we propose a two-stage prompting framework and instantiate CreativeDC, a method for generating diverse contextualized programming tasks. Given a theme and a programming concept as context, CreativeDC instructs the LLM to first go through a *divergent thinking stage*, where it explores the creative space of ideas with respect to the input theme. Then, in the following *convergent thinking stage*, the model refines promising ideas into a valid programming task using the given programming concept. This decoupling encourages the LLM to explore a broader ideation space before committing to a final task. Our main contributions are:

1. We propose a novel prompting framework with divergent-convergent thinking stages and develop CreativeDC, a method for generating diverse programming tasks.
2. We define and propose approaches to evaluate effective diversity, which measures the number of distinct tasks among high-utility tasks.
3. We show through automated and expert evaluations that CreativeDC achieves significantly higher effective diversity than baseline methods.

Figure 1 shows an overview of our method. We release our code and data publicly to support future research.[1]

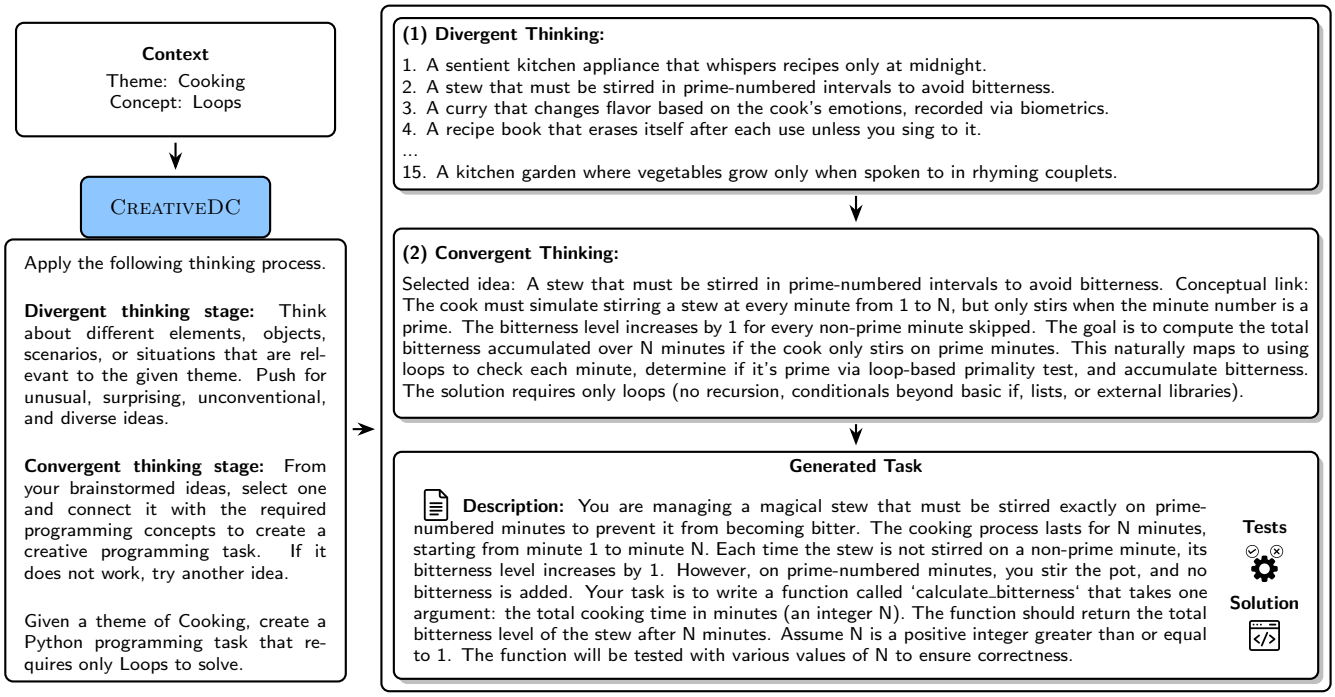

Figure 1: Overview of CreativeDC for programming task generation. The input is a context containing a theme and a programming concept. Our method instructs an LLM to apply a two-stage reasoning process: *(1) Divergent thinking stage* and *(2) Convergent thinking stage*. The generated task consists of a description, a test suite, and a solution.

2. RELATED WORK

LLMs for Task Generation. LLMs have been used to generate educational tasks across domains, including topic-specific questions, mathematics word problems, and programming exercises [2–9]. In programming education, recent work has generated multiple-choice items and contextualized tasks [15–18]. However, these works primarily optimize task correctness or difficulty alignment, whereas we also consider the diversity of generated tasks.

Diversity Collapse of LLMs. LLMs exhibit an "Artificial Hivemind" effect, characterized by high intra-model and inter-model homogeneity [22]. Post-training alignment further amplifies this convergence [28] and reduces LLM creativity and output novelty [29]. Moreover, LLMs have been shown to lack novelty [23, 29] and suffer from "functional fixedness", a bias that limits unconventional thinking [30]. These findings motivate methods that explicitly scaffold exploration rather than direct prompting alone.

Improving Diversity of LLM Outputs. Methods have been proposed to promote diversity in LLM outputs, including fine-tuning with creativity signals [23], multi-agent frameworks [24, 31], and persona simulation for diverse perspectives [21]. However, these methods are primarily designed for open-ended generation settings such as creative writing. Our work instead targets educational task generation, where outputs must balance diversity with utility.

3. PROBLEM SETUP

We formalize the problem of generating diverse tasks, discuss the metrics for evaluation, and state our objective.

Preliminaries. We denote a programming task as a tuple $\mathcal{P} = (\mathcal{P}_{\text{desc}}, \mathcal{P}_{\text{eval}}, \mathcal{P}_{\text{sol}})$, where $\mathcal{P}_{\text{desc}}$ is a natural-language task description, $\mathcal{P}_{\text{eval}}$ is an evaluation guide or final answer for checking the correctness of any answer, and $\mathcal{P}_{\text{sol}}$ is a reference solution. Given a context $\mathcal{C}$, which specifies the requirements for task generation, and an integer K, we seek to generate a set of tasks that satisfy $\mathcal{C}$. We denote the generated set of K tasks as $\mathcal{S}(\mathcal{C}) = \{\mathcal{P}_1, \mathcal{P}_2, \ldots, \mathcal{P}_K\}$. For example, if $\mathcal{C}$ corresponds to a learning concept, we aim to generate K tasks that help students practice that concept.

Metrics. We evaluate a task set $\mathcal{S}(\mathcal{C})$ along the following metrics. *Diversity* captures the degree of task variation and is defined as the number of semantically distinct tasks in $\mathcal{S}(\mathcal{C})$. *Utility* captures whether a task $\mathcal{P} \in \mathcal{S}(\mathcal{C})$ is valid, comprehensible, and relevant to the given context. We assign $\text{Utility}(\mathcal{P}) = 1$ if it meets these criteria and 0 otherwise. We define the subset of high-utility tasks as $\mathcal{S}_{\text{util}=1}(\mathcal{C}) = \{\mathcal{P} \in \mathcal{S}(\mathcal{C}) \mid \text{Utility}(\mathcal{P}) = 1\}$. We define *Effective Diversity* as the diversity of this high-utility subset. Intuitively, it measures the number of distinct high-utility tasks. We detail the measurement of these metrics in Section 5.

Objective. Our goal is to design a method that, given a context $\mathcal{C}$, produces a set of K tasks $\mathcal{S}(\mathcal{C})$ with high *effective diversity*. This objective is challenging because encouraging diverse outputs can conflict with the utility constraints [32].

In this work, we instantiate this setup for the generation of programming tasks given a context, following prior work on contextualized programming tasks [15–17]. Figure 1 illustrates an example context and a generated task.

Table 1: Prompts for all methods. {placeholder} is replaced with the actual theme and concept for each context.

BASE
Task Instruction Given a theme of {theme}, create a Python programming problem that requires only {concept} to solve. The problem should include a problem description, a test suite, and a solution program. Below are the requirements for the problem: • The problem must be clearly relevant to the given theme of {theme} and the theme is explicitly used throughout. It requires only {concept} to solve the problem. • The problem description must be sensible and sound natural. It must provide comprehensive information required to solve the problem and pass the test suite (e.g., how the program will be tested, function signatures). Do not use type hints. Do not mention the required programming concepts in the problem description. • The test suite must consist of at least 5 comprehensive test cases written in the Pytest framework format. The testsuite must be correct and cover both base and corner cases. If the test suite involves handling files and I/O, the related files should be created using 'setup_module()' and removed using 'teardown_module()' functions in the Pytest framework. Everything from the solution program will be imported manually; do not import anything else except 'pytest' and 'os'. Do not use multiple assert statements in a single test case. • The solution program must use only {concept}. Do not include any comments, usage examples, or tests in the solution program. The solution program must pass the test suite. # Output Format Output a JSON object with the following keys: `'description'`, `'test_suite'`, and `'solution'`.
COT
Think step by step to generate a problem. # Task Instruction (same as in BASE) # Output Format Output a JSON object with the following keys: `'chain_of_thought'`, `'description'`, `'test_suite'`, and `'solution'`.
CREATIVEDC
Apply the following thinking process to generate a problem. *Divergent thinking phase:* Think about only the given theme and list down wildly different and underexplored elements, objects, scenarios, or situations that are relevant. Ignore the required programming concepts in this phase. Push for unusual, surprising, unconventional, and diverse ideas. Explore the creative space related to the theme as much as possible. *Convergent thinking phase:* From your brainstormed ideas, select one and connect it with the required programming concepts to create a creative programming problem. Make sure the problem does not require any other programming concepts other than the given programming concepts. If it does not work, feel free to go back to select another idea and try again. # Task Instruction (same as in BASE) # Output Format Output a JSON object with the following keys: `'divergent_thinking'`, `'convergent_thinking'`, `'description'`, `'test_suite'`, and `'solution'`.

4. OUR METHOD: CREATIVEDC

We draw inspiration from creativity literature and staged models [25–27] to propose a two-stage prompting framework that structures the model's reasoning into *divergent thinking* and *convergent thinking* stages. Divergent thinking aims to generate many diverse ideas without judgment, while convergent thinking selects and refines the best ideas into a concrete solution. We instantiate this framework as CREATIVEDC (**Creative D**ivergent-**C**onvergent) (cf. Figure 1).

Stage 1: Divergent Thinking. In this stage, CREATIVEDC instructs the LLM to explore the thematic space of context $\mathcal{C}$ without imposing any constraints from the target programming concept in $\mathcal{C}$. By focusing only on the theme, the model is encouraged to brainstorm varied and underexplored elements, objects, scenarios, or situations. Pushing for unusual, surprising, and unconventional ideas helps the model traverse a broader semantic space. The goal of this stage is to avoid the premature convergence often seen in direct prompting, where the model settles too quickly on ideas that satisfy the technical requirements but offer limited variety.

Stage 2: Convergent Thinking. In the second stage, CREATIVEDC instructs the model to select one promising idea from the brainstormed list and refine it into a valid programming task $\mathcal{P}$. The output must satisfy all requirements of $\mathcal{C}$ and, crucially, primarily test the specified programming concept. If the selected idea cannot be developed into a valid task, the model is encouraged to return to the brainstormed list and try another idea. In this way, the convergent stage uses the broader idea pool produced by Stage 1 while enforcing the constraints required for utility.

After going through the two stages, the model outputs the final task $\mathcal{P} = (\mathcal{P}_{\text{desc}}, \mathcal{P}_{\text{eval}}, \mathcal{P}_{\text{sol}})$. Figure 1 illustrates the two stages of our method with an example generated task.

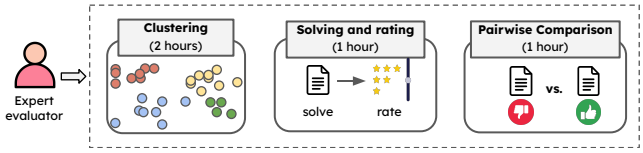

Figure 2: Overview of Expert Evaluation.

5. EVALUATION SETUP

In this section, we present an evaluation setup designed to answer the following questions: **(i)** How does effective diversity scale with the number of generated tasks? **(ii)** How do expert evaluators perceive the generated tasks?

Task Contexts. We use a set of 20 task contexts, each of which is a pair of a theme and a target programming concept following prior work on contextualized tasks [15–17]. We use 4 themes ("Cooking", "Science Fiction", "Superheroes", and "Board Games") and 5 concepts ("Variables", "Selection Statements", "Loops", "Lists", and "Strings"). For each context, we generate K tasks per method. We report the results for $K \in \{10, 20, 30, 40, 50\}$ in Section 6.

Methods. We compare CreativeDC (described in Section 4) against two baselines: Base and CoT. Base directly prompts the model to generate a task from the given theme and concept. CoT prepends a "Think step by step" instruction to the Base prompt to elicit intermediate reasoning [33]. Table 1 shows the prompts for all methods. For all methods, we use Qwen3-235B-A22B [34], a strong open-weight model, enabling reproducible generation. We set the temperature to 1.0.

Expert-based Evaluation Overview. We use a mix of automated and expert-based evaluation as further discussed in Section 5.1 and Section 5.2. We present an overview of our expert evaluation for assessing diversity and multiple task aspects in Figure 2. More concretely, we recruited three experts with experience in programming education and tutoring in programming-related courses. All three are non-native English speakers (one female, two males; mean age 28.7 years), and none are authors of this paper. Participation was voluntary, and no personally identifiable data was collected. Each expert evaluator was assigned the same programming concept ("Variables") and a randomly sampled theme. We use small subsets of tasks generated during the automated evaluation to reduce the workload. We exclude Base from expert evaluation due to similar performance to CoT in automated evaluations (cf. Section 6). To maintain objectivity, the source of each task remained undisclosed throughout the study.

5.1 Measuring Effective Diversity

We measure the effective diversity of a task set $\mathcal{S}$ (defined in Section 3), which requires evaluating both task diversity and task utility. Below, we present two approaches we used to evaluate the set diversity: automated and expert-based.

- **Automated Vendi Score.** We use the Vendi Score [35] to measure task diversity automatically. Given a set of tasks, it ranges from 1 (all tasks identical) to $|\mathcal{S}|$ (all tasks dissimilar), quantifying the number of distinct tasks in $\mathcal{S}$. To begin, each task $\mathcal{P}$ is represented by an embedding obtained from a model (Qwen3-Embedding-0.6B [36]). Given the task embeddings, we construct a cosine similarity matrix and compute the Vendi Score as the exponential of the Shannon entropy of its eigenvalues.
- **Expert-based Clustering.** We involve expert evaluators to assess task diversity through clustering the generated tasks. Given a set of tasks, an evaluator either assigns each task to a cluster based on its semantic similarity to other tasks in the set or creates a new cluster for the task. The number of final clusters provides an expert-annotated measure of task diversity, corresponding to the number of distinct tasks as judged by experts.

Next, we describe how we measure effective diversity which is defined as the diversity (number of distinct tasks) of the high-utility subset $\mathcal{S}_{\text{util}=1}(\mathcal{C})$ (cf. Section 3). To this end, we need to evaluate the utility of generated tasks. For scalability, we use an LLM-as-a-judge approach, which has been used in prior work including task utility evaluation [15, 22, 32]. Given a task $\mathcal{P}$, the judge first generates a solution, which is executed against $\mathcal{P}_{\text{eval}}$ to verify *Task Validity*. The judge then assesses *Context Relevance* (whether the task is relevant to the given context) and *Comprehensibility* (whether sufficient information is provided). Utility$(\mathcal{P}) = 1$ if the task $\mathcal{P}$ satisfies all three criteria. We use Gemini 2.5 Flash-Lite [37] as the judge, chosen for its cost-effectiveness. Using a model from a different family than the generator also avoids self-preference bias.

5.2 Measuring Other Task Aspects

Beyond diversity metrics, we asked experts to perform additional evaluations on small subsets of generated tasks. More specifically, each evaluator solved and rated 6 tasks (3 from CoT and 3 from CreativeDC) via a web interface (providing a task description, code editor, and console). After completing a task or reaching a 10-minute limit, evaluators rated *Theme Relevance*, *Concept Relevance*, *Task Validity*, and *Comprehensibility* on 3-point Likert scales (e.g., Relevant / Partially Relevant / Irrelevant). Supplementary dimensions included *Difficulty* (3-point) and *Interestingness* (5-point). After finishing the task ratings, we asked each evaluator to perform pairwise comparison in terms of novelty. Each pair comprised one task from CoT and one task from CreativeDC. We randomly sampled 20 pairs of tasks. For each pair, the evaluator selected the more novel task and wrote a brief justification.

6. RESULTS

We present the effective diversity with respect to the number of tasks K in Figure 3 and ratings for other task aspects in Table 2.

6.1 Effective Diversity

Effective Diversity via Automated Vendi Score. Figure 3a shows that all methods generate more distinct tasks as the number of tasks K increases. Notably, CreativeDC significantly outperforms both CoT and Base across all K values ($p < 0.001$, Bonferroni-corrected paired Wilcoxon signed-rank tests [38]), while CoT and Base are statistically indistinguishable. At $K = 50$, CreativeDC generates about 13

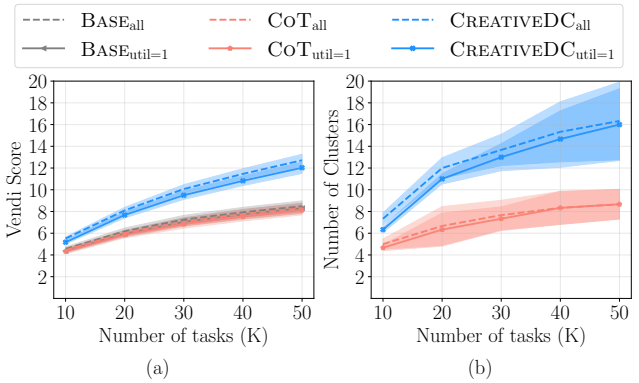

Figure 3: Effective diversity with respect to number of tasks K via (a) automated Vendi scores and (b) expert evaluation. Solid lines denote effective diversity (diversity of high-utility tasks only) and dashed lines denote diversity over all tasks. Shaded bands show SE across contexts. CreativeDC consistently outperforms baselines across both evaluations.

distinct tasks (dashed blue line), and about 12 distinct tasks when restricted to high-utility tasks only (solid blue line). In contrast, both CoT and BASE generate about 8 distinct high-utility tasks (solid red and grey lines).

Effective Diversity via Expert Evaluation. Figure 3b shows that effective diversity perceived by experts has a similar pattern but is generally higher than the automated Vendi Score. For instance, evaluators created about 16 clusters at $K = 50$ for CREATIVEDC when restricted to high-utility tasks, compared to about 9 clusters for CoT. While CoT shows signs of saturation, CREATIVEDC maintains an upward trend. Because each expert evaluated a uniquely themed subset of tasks, inter-rater agreement measures are not applicable. This evaluation provides evidence that the automated metric we used can serve as a proxy for expert-perceived diversity.

6.2 Expert Ratings for Other Task Aspects

We compute the average expert ratings (cf. Section 5.2) by mapping 3-point scales to $\{1, 0.5, 0\}$ and 5-point scales to $\{1, 0.75, 0.5, 0.25, 0\}$. Table 2 shows that tasks generated by CREATIVEDC were judged higher than those from CoT on the utility-related submetrics. Tasks generated by both methods were perceived as between easy and medium in difficulty. Notably, CREATIVEDC tasks were rated higher in interestingness (0.81 vs. 0.50) and were preferred in 96.67% of pairwise novelty comparisons. Justifications for experts' decisions favoring tasks generated by CREATIVEDC include: "It makes the cooking theme and the question very life-like"; "Trading recorded personal experiences as currency is definitely novel to me–the problem even opens up my mind for new possibilities that may really happen in the future".

7. CONCLUDING DISCUSSION

We proposed CREATIVEDC, a method for generating diverse and high-utility tasks in programming education. Through automated and expert evaluations, CREATIVEDC has been shown to produce more distinct high-utility programming tasks, improving the effective diversity of generated tasks.

Table 2: Expert evaluator ratings (means ± SE) for various task aspects: utility, novelty, and difficulty. Highest scores are bolded for metrics where higher is better (↑).

Metric	CoT	CREATIVEDC
Utility:TaskValidity ↑	0.78 ± 0.15	**1.00 ± 0.00**
Utility:ThemeRelevance ↑	0.94 ± 0.06	**1.00 ± 0.00**
Utility:ConceptRelevance ↑	0.89 ± 0.07	**0.94 ± 0.06**
Utility:Comprehensibility ↑	0.72 ± 0.15	**0.83 ± 0.08**
Novelty:Interestingness ↑	0.50 ± 0.04	**0.81 ± 0.04**
Novelty:Win Rate (%) ↑	3.33 ± 2.32	**96.67 ± 2.32**
Difficulty:Self-rated	0.17 ± 0.08	0.17 ± 0.08
Difficulty:Pass Rate (%)	88.89 ± 11.11	100.00 ± 0.00
Difficulty:Time Taken (mins)	3.84 ± 0.55	3.38 ± 0.61

Next, we discuss limitations of our work and suggest future directions. First, our evaluation focused on introductory programming concepts; extending this framework to other educational domains, such as mathematics or science, would demonstrate its generalizability. Second, while our expert study provides initial validation, it is limited by its sample size and demographic diversity; it would be useful to conduct large-scale studies to evaluate the tasks from the perspective of students. Third, the two stages in our method can be iterated in a loop to improve the quality of the generated tasks; exploring this iterative process is a promising direction. Fourth, our experiments focus on introductory Python programming concepts; it would be useful to check whether this diversity holds in harder problems with advanced concepts and whether diversity across difficulty levels can be enforced while maintaining the effective validity and utility of the generated tasks. Finally, our evaluation focused on theme and concept as a task context; expanding the context to include learner-state contextualization (e.g., difficulty, student profiles) is a natural next step for generating diverse and personalized tasks.

ABSTRACT

Educational prediction models are increasingly used to identify students who may need early academic support. When such models are trained with privacy-preserving methods, evaluation often focuses on average predictive performance and measured privacy leakage. However, this can overlook an important deployment concern: private training may also change how prediction errors are distributed across student groups. We examine this issue using two public educational datasets. OULAD serves as the primary dataset because it supports both privacy auditing and group-level error analysis, while UCI697 is used only as a secondary consistency check for the relationship between private training, predictive quality, and measured privacy leakage. Across both datasets, we compare standard non-private training with Differentially Private Stochastic Gradient Descent (DP-SGD). We evaluate predictive quality using test AUC, measured privacy leakage using a loss-based membership inference attack, and, on OULAD, group-level error patterns using worst-group gaps in true positive rate and false positive rate. Across both datasets, stronger private training reduces predictive quality more clearly than it changes the measured privacy-audit outcome. On OULAD, under the fixed threshold used for controlled comparison, privacy-preserving training also increases group-level error gaps. These results suggest that evaluating student prediction models only through average predictive performance and measured privacy leakage can miss an important part of the effect of privacy-preserving training. Educational prediction models trained with privacy-preserving methods should be evaluated jointly in terms of predictive quality, measured privacy leakage, and group-level error patterns, especially when they are used to inform student support decisions. 1. INTRODUCTION

Prediction models are increasingly used to identify students who may be at risk of failure, withdrawal, or dropout [1, 2, 3]. These models are sometimes trained on sensitive educational records, including demographic information, academic histories, and learning activity traces. The collection and use of such records raise concerns about student privacy, consent, transparency, and institutional responsibility [4]. Privacy protection is therefore needed because trained machine learning models may reveal information about the records used during training, including whether a particular student's record was included [5, 6].

Prior work has developed privacy-preserving training methods such as DP-SGD [7, 8]. Evaluations of such methods commonly consider predictive performance and measured privacy leakage. Predictive performance describes how well a model distinguishes between students with different outcomes, whereas measured privacy leakage examines whether information about individual training records remains detectable from the trained model. For example, a membership inference attack tests whether an attacker can determine whether a particular user record was included in the training data [5, 6]. One common audit is membership inference, which tests whether an attacker can determine whether a particular student record was included in the training data. Membership inference does not necessarily reveal a student's identity or complete educational record. However, when an attacker already has auxiliary information about a student, evidence of training-set membership may strengthen an association between that student and sensitive information, such as course participation, academic difficulty, dropout risk, or receipt of educational support. For this reason, reducing measured privacy leakage is an important goal of privacy-preserving training. However, privacy and utility alone may still provide an incomplete view of model behaviour in deployment [9]. A model may maintain usable predictive performance and show little detectable membership signal under a selected privacy attack, while still changing how prediction errors are distributed across student groups.

In practical implementation, prediction models may influence which students are identified for support, which students are overlooked, and which students are incorrectly flagged for intervention. Therefore, even when a privacy-preserving model retains usable overall predictive performance and shows little detectable membership signal under a selected privacy attack, it may still distribute prediction errors unevenly across

student groups. This matters because uneven error patterns can create unequal consequences for students: some groups may be more likely to receive timely support, while others may be more likely to be missed or unnecessarily targeted for intervention. Thus, in addition to evaluating overall model quality and measured privacy leakage, privacy-preserving training should also be evaluated in terms of how prediction errors are distributed across student groups.

This study investigates this deployment concern by examining whether the introduction of privacy-preserving training changes not only predictive quality and measured privacy leakage, but also the distribution of prediction errors across student groups. Specifically, we compare standard non-private training with Differentially Private Stochastic Gradient Descent (DP-SGD), a widely used privacy-preserving training method that clips per-example gradients and adds noise during optimisation [7, 8]. We use OULAD as the primary dataset because it supports both privacy auditing and group-level error analysis, and we use UCI697 as a secondary case to test whether the relationship between privacy protection and predictive quality also appears in another educational setting [3, 10].

To evaluate individual-level privacy risk, we use a membership inference attack (MIA), which tests whether an attacker can distinguish a student record used for model training from a record that was not used for training [5, 6]. This attack provides one operational measure of whether information about an individual training record remains detectable from the trained model. To evaluate group-level consequences, we examine whether privacy-preserving training changes how prediction errors are distributed across student groups [1, 2]. These two concerns are commonly studied through different evaluation traditions. Privacy research often focuses on formal privacy guarantees or attack-based audits of individual records [5, 6], whereas educational prediction research commonly evaluates average predictive performance and examines group fairness as a separate dimension [11, 12]. Evaluating these dimensions separately can obscure an important deployment concern: a model may retain usable average predictive performance and show little detectable membership signal under a selected privacy attack, while still producing more uneven error patterns across student groups after privacy-preserving training is introduced. This study contributes an integrated evaluation perspective for privacy-preserving educational prediction by examining predictive quality, measured individual-level privacy leakage, and group-level error patterns within the same empirical comparison. This joint evaluation makes visible whether private training changes not only average model performance and detectable membership signals, but also which student groups are more likely to be correctly identified, overlooked, or incorrectly flagged for support. As introduced in Figure 1, our study is guided by two Research Questions (**RQs**):

RQ1. How does private training change predictive quality and measured privacy leakage in educational prediction?

RQ2. Does private training also change group-level error patterns in ways that would be missed by evaluation based only on utility and privacy audit?

2. METHOD

Our evaluation has three parts, each aligned with the paper's central question: predictive quality, measured privacy leakage, and group-level error patterns. Predictive quality is evaluated using test AUC. Measured privacy leakage is evaluated using a loss-based membership inference attack. Group-level error patterns are evaluated on OULAD using worst-group gaps in true positive rate (TPR) and false positive rate (FPR).

2.1 Datasets and prediction tasks

We use two public educational datasets with different roles in the study. OULAD is the primary dataset because it is the only dataset in our experiments that supports all three parts of the analysis within a single setting: predictive quality, privacy auditing, and group-level error evaluation [3]. UCI697 is used only as a secondary consistency check for the relationship between private training, predictive quality, and measured privacy leakage [10].

The Open University Learning Analytics Dataset (OULAD) contains 32,593 student-course records with course outcomes and demographic attributes such as gender, region, age band, and education level [3]. The prediction task in this study is course failure or withdrawal. We use structured student and course features, including previous attempts, studied credits, and categorical variables converted into numeric form.

The UCI Student Dropout and Academic Success dataset (UCI697) contains 4,424 higher education records and 36 features related to enrolment background and academic progress [10]. The prediction target is dropout versus graduation. We do not use UCI697 for group-level error analysis in this study. For both datasets, all training conditions use the same preprocessing pipeline within each dataset, so comparisons are between training conditions rather than between different feature sets or preprocessing choices.

2.2 Training setup and split protocol

We compare standard non-private training with Differentially Private Stochastic Gradient Descent (DP-SGD) [7]. DP-SGD modifies ordinary gradient-based training in two steps: it clips each example's gradient to bound the influence of any single training record, and then adds Gaussian noise to the aggregated clipped gradients during optimisation. In our experiments, the clipping norm is fixed at $C = 1.0$. We evaluate privacy budgets $\epsilon \in \{1, 5, 10\}$ and set $\delta = 1/n_{\text{train}}$, with smaller ϵ corresponding to stronger privacy protection.

We use logistic regression as a simple linear baseline and a small multilayer perceptron (MLP-small) as the main nonlinear baseline for matched comparisons. MLP-small is chosen to compare private and non-private training under the same feature representation. Across conditions, the model family, feature inputs, data splits, and evaluation protocol are held fixed. The main change is whether DP-SGD is applied during training. All conditions are run with matched random seeds, and each reported result summarises five runs per condition. For each run, models are trained on a training split and evaluated on the same held-out test split for predictive quality, privacy, and, where applicable, group-level error analysis. This keeps the comparison focused on the effect of private training rather than on differences in data partitioning.

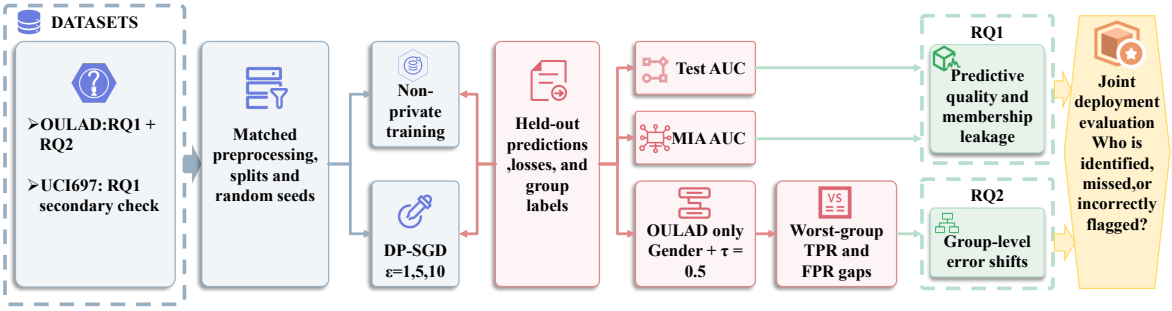

Figure 1: Study design aligned with the two research questions. Both datasets are used to compare non-private training with DP-SGD. RQ1 focuses on predictive quality and privacy leakage. RQ2 focuses on group-level error shifts and is evaluated on OULAD only.

2.3 Privacy audit and group-level error evaluation

To evaluate measured privacy leakage, we use the loss-based membership inference attack proposed by Yeom et al. [6]. In this attack, the attacker uses prediction loss as the signal, with lower-loss examples treated as more likely to be training members. For each run, the attack compares training members with held-out non-members from the same split used for model evaluation. We report membership inference attack AUC, which measures how well the attack separates training members from non-members. An AUC close to 0.5 indicates near-random separation, whereas a larger value indicates stronger measured membership signal. We use this attack as one measured privacy audit under a specific threat model, rather than as a complete characterisation of privacy risk in educational prediction.

To evaluate group-level error patterns on OULAD, we compare two worst-group error gaps across gender groups. We use gender as a first group-based check because this attribute is complete and consistently represented in the OULAD records used here. The first metric is the worst-group gap in true positive rate, and the second is the worst-group gap in false positive rate. For a group g, TPR_g is the proportion of positive cases in that group that the model correctly predicts as positive, and FPR_g is the proportion of negative cases in that group that the model incorrectly predicts as positive. We report

$$\Delta_{\mathrm{TPR}} = \max_g \mathrm{TPR}_g - \min_g \mathrm{TPR}_g$$

and

$$\Delta_{\mathrm{FPR}} = \max_g \mathrm{FPR}_g - \min_g \mathrm{FPR}_g.$$

A larger TPR gap means that some groups are more likely than others to receive correct positive predictions, whereas a larger FPR gap means that some groups are more likely than others to receive incorrect positive predictions. All group-level error results use a fixed decision threshold of 0.5 to support controlled comparison across training conditions. This choice is intended to isolate changes in model behaviour rather than to represent an optimal deployment threshold.

3. RESULTS

3.1 RQ1: Privacy-preserving training on predictive quality and measured leakage

Table 1 reports the main OULAD results across five matched random seeds per condition. For RQ1, we examine two outcomes commonly used to evaluate private training: predictive quality and measured privacy leakage. Table 2 reports the corresponding utility–privacy patterns on UCI697 as a secondary consistency check.

We begin with predictive quality. On OULAD, the non-private MLP-small baseline achieves a test AUC of 0.661 ± 0.004. Under DP-SGD with $\epsilon = 1$, test AUC decreases to 0.644 ± 0.002, and partially recovers to 0.649 ± 0.002 at $\epsilon = 5$ and $\epsilon = 10$. This pattern is consistent with the expected privacy–utility trade-off: stronger privacy protection produces the largest reduction in predictive quality, whereas looser privacy budgets recover some utility. UCI697 shows the same pattern. There, the non-private baseline achieves the highest test AUC, 0.952 ± 0.008, DP-SGD at $\epsilon = 1$ yields the largest drop to 0.919 ± 0.012, and performance improves again at $\epsilon = 5$ and $\epsilon = 10$. Across both datasets, private training therefore changes predictive quality in the expected direction.

The measured privacy-leakage results require a more cautious reading. On OULAD, the loss-based membership inference attack AUC remains close to random guessing in all conditions, including the non-private baseline. This is therefore better interpreted as evidence that the evaluated attack is already weak in this setting, rather than evidence that DP-SGD removes a strong privacy leakage signal. Additional analysis supports this interpretation: member and non-member scores are already highly similar before private training is applied. The UCI697 results support the same reading, with membership inference attack AUC remaining close to 0.5 across all conditions.

Taken together, the RQ1 results show that private training changes predictive quality more clearly than it changes the measured privacy-audit outcome. This means that evaluation based only on utility and privacy audit provides only a partial view of its effects.

Table 1: Main results on OULAD, with 5 seeds per condition. Test AUC measures predictive quality. Membership inference attack (MIA) AUC measures how well a loss-based attack separates training members from non-members. TPR and FPR gaps measure group-level error differences across gender groups.

Condition	Test AUC	MIA AUC	TPR Gap	FPR Gap
LR Baseline	0.640 ± 0.002	0.501 ± 0.001	0.063 ± 0.010	0.075 ± 0.015
MLP-small Baseline	0.661 ± 0.004	0.506 ± 0.003	0.016 ± 0.009	0.009 ± 0.002
MLP-small DP-SGD $\epsilon = 1$	0.644 ± 0.002	0.503 ± 0.001	0.045 ± 0.014	0.064 ± 0.014
MLP-small DP-SGD $\epsilon = 5$	0.649 ± 0.002	0.503 ± 0.002	0.031 ± 0.016	0.046 ± 0.012
MLP-small DP-SGD $\epsilon = 10$	0.649 ± 0.002	0.503 ± 0.002	0.028 ± 0.019	0.042 ± 0.011

Table 2: UCI697 results, used only as a privacy–utility consistency check.

Condition	Test AUC	MIA AUC
Baseline	0.952 ± 0.008	0.502 ± 0.013
DP-SGD $\epsilon = 1$	0.919 ± 0.012	0.495 ± 0.013
DP-SGD $\epsilon = 5$	0.938 ± 0.012	0.495 ± 0.014
DP-SGD $\epsilon = 10$	0.941 ± 0.012	0.494 ± 0.013

3.2 RQ2: Privacy-preserving training on group-level error patterns

RQ2 examines the part of model behaviour that would be missed if evaluation were limited to predictive quality and privacy audit. This analysis is conducted only on OULAD, the only dataset in this study that supports group-level error evaluation. The answer is yes: under the fixed threshold used here, private training changes how prediction errors are distributed across groups.

Relative to the non-private MLP-small baseline, both worst-group error gaps increase under private training. At $\epsilon = 1$, the TPR gap rises from 0.016 ± 0.009 to 0.045 ± 0.014, and the FPR gap rises from 0.009 ± 0.002 to 0.064 ± 0.014. At $\epsilon = 5$ and $\epsilon = 10$, both gaps remain above the non-private baseline, although they are smaller than at $\epsilon = 1$. This indicates that the shift is not confined to the strictest privacy condition, even if it is most pronounced there.

This finding matters because the change in group-level error patterns appears alongside only a modest change in overall AUC. On OULAD, private training does not remove the model's predictive usefulness, but it does alter how support-related errors are distributed across groups. A deployment decision based only on average predictive quality and privacy audit could therefore conclude that the private model remains broadly acceptable, while missing that the pattern of errors across groups has shifted.

The two gap types also have distinct practical interpretations. A larger TPR gap means that some groups are more likely than others to receive correct positive predictions, whereas a larger FPR gap means that some groups are more likely than others to receive incorrect positive predictions. In educational settings, these differences can translate into unequal access to intervention or unequal exposure to unnecessary intervention, even when the model still appears acceptable on average performance metrics.

Taken together with RQ1, these results show why utility and privacy audit alone are not sufficient for evaluating private training in educational prediction. In settings such as OULAD, private training changes not only overall utility, but also how support-related errors are distributed across groups.

4. DISCUSSION

This study shows that private training can change more than average predictive performance and measured privacy leakage. On OULAD, DP-SGD reduced predictive quality to some extent, while the evaluated loss-based membership inference attack remained close to random across both private and non-private conditions. When evaluation stopped at these two dimensions, the training conditions might appear similar under the selected privacy audit, even though the audit provides limited evidence because attack performance was already close to random for the non-private model. However, the same models produced larger worst-group TPR and FPR gaps under the fixed decision threshold used for comparison. This indicates that private training can alter the distribution of support-related prediction errors even when average predictive performance remains usable and the selected privacy audit detects little membership signal.

4.1 Implications

The practical importance of this finding lies in how educational prediction models are used. In student-risk modelling, predictions are often connected to advising, tutoring, outreach, or other forms of early support. A true positive can correspond to a student being correctly identified for support, whereas a false negative can correspond to a student being overlooked. Similarly, a false positive can expose students to unnecessary intervention or concern. Group-level shifts in TPR and FPR therefore matter because they may change which groups are more likely to receive support, be missed, or be incorrectly flagged. The contribution of this paper is to make this deployment issue visible in the evaluation of privacy-preserving educational prediction models.

This finding also has a methodological implication for educational data mining. Privacy, predictive performance, and group-level error behaviour are often evaluated as separate concerns. The present results suggest that this separation can be incomplete when prediction models are used to inform student support. In this setting, average utility and the evaluated privacy audit alone would not have shown that private training also changed who was more likely to be correctly identified, overlooked, or unnecessarily flagged. Evaluating these dimensions jointly therefore provides a more

deployment-relevant view of privacy-preserving educational prediction.

4.2 Limitations and Future Work

Several limitations define the scope of the findings. *First*, the privacy audit uses only one loss-based membership inference attack, which detected little separation between members and non-members even before private training. The results therefore should not be interpreted as evidence that DP-SGD removed a strong membership signal or as a complete assessment of privacy risk. Future work should examine stronger and complementary attacks, including confidence-based, entropy-based, shadow-model, label-only, and white-box attacks. *Second*, the group-level analysis is limited to gender groups in OULAD and to worst-group TPR and FPR gaps. Future studies should examine additional attributes, intersectional groups, and complementary metrics such as FNR, positive prediction rate, positive predictive value, and calibration error. *Third*, the fixed threshold of 0.5 supports controlled comparison but does not represent all institutional intervention rules. Future work should test whether similar shifts appear across thresholds and realistic support-allocation policies. *Fourth*, the analysis documents group-level error shifts but does not identify their causes. Further work should examine whether these shifts arise from gradient clipping, added noise, subgroup size, class imbalance, or feature-distribution differences. *Finally*, the study uses two public datasets and relatively simple models. The findings should therefore be tested with larger datasets, richer model families, and deployment settings where student identifiability, privacy risk, and intervention consequences can be evaluated more directly.

5. CONCLUSION

This paper investigated how privacy-preserving training changes predictive quality, measured privacy leakage, and group-level error patterns in educational prediction. Across two public datasets, stronger privacy-preserving training consistently reduced predictive quality, while the evaluated loss-based membership inference attack remained close to random. On OULAD, privacy-preserving training also changed worst-group TPR and FPR gaps across gender groups.

These findings show that evaluating privacy-preserving training only as a privacy–utility trade-off can provide an incomplete account of its deployment effects. A model may retain usable average predictive performance and show little measured leakage under a particular membership inference attack, while still changing how prediction errors are distributed across student groups. In educational settings, this matters because such errors may affect which students are correctly identified for support, which students are overlooked, and which students are unnecessarily flagged for intervention.

The main contribution of this paper is therefore to broaden the evaluation frame for privacy-preserving educational prediction. Rather than treating predictive quality, measured privacy leakage, and group-level error patterns as separate concerns, our results suggest that they should be examined jointly when student prediction models are used to inform support decisions. This joint evaluation is especially important in contexts where privacy-preserving training is adopted to protect student data, but the resulting models may still have unequal consequences across student groups.

ABSTRACT

The transition into higher education is a critical phase. In Austria, it is structured through the Study Entry and Orientation Phase (StEOP), a formally mandated introductory phase. Despite its central role, corresponding regulations are specified in natural language, making them difficult to interpret, compare, and analyse. This paper addressed this challenge by proposing a formal model of StEOP regulations based on nested course pools and credit requirements. To operationalise the model, we introduce a semi-automated extraction approach. Results show that all but one of the analysed StEOPs can be consistently mapped to the proposed model. By introducing a formal model of the StEOP and empirically validating its applicability, this work enables the systematic analysis and comparison of curriculum designs, laying the foundation for data-driven evaluation of study entry phases.

Curriculum Modelling, Formalisation, Constraint Satisfaction Problems, Rule Extraction, Data Mining

1. INTRODUCTION

The transition to higher education (HE) represents a critical phase for many students, often marked by uncertainty about study requirements and expectations. To facilitate this transition, universities have implemented various support mechanisms. In Austria a structured introductory phase – the **St**udy **E**ntry and **O**rientation **P**hase (StEOP) – has been introduced. The StEOP defines a set of courses with additional constraints that students must complete before they can enrol in more advanced courses. The aim of the StEOP is to provide an early overview of the study program's content and requirements, enabling students to make informed decisions about whether the chosen field of study aligns with their interests and abilities, and to serve as a regulatory mechanism.

While the StEOP is implemented nationwide and follows general regulatory guidelines, its concrete design and structure are defined individually for each study program. These specifications are described in textual form within the official curricula. However, there is no standardised formal model or machine-readable representation of these regulations. Without such a formal representation, systematically analysing and understanding how curriculum design – particularly different StEOP implementations – affects student progression and success remains challenging. This work addresses this gap by proposing a formal model of StEOP regulations, introducing a semi-automated extraction approach, and empirically evaluating the model's validity. Thus, we aim to answer the following research questions:

RQ1 How can the StEOP structure be formally modelled?

RQ2 To what extent can different StEOP implementations be accurately represented using the proposed model?

2. RELATED WORK

Our work relates to and extends existing work in the fields of curriculum analytics (CA) and educational data mining (EDM), especially prior research on curriculum modelling, study planning, and formal representations of study regulations: Study regulations are typically specified in natural language, which makes them accessible to humans but difficult to process computationally. This gap introduces challenges such as ambiguity and limited support for automated analysis and verification [3]. Therefore, modelling curriculum regulations (e.g., StEOPs) in a formal, machine-readable way remains an important topic in educational technology (EdTech) and EDM, where structured representations are a prerequisite for large-scale analysis. Prior work has approached curriculum modelling from different perspectives, including structural analysis [1], formal verification [6], and individual study planning [7]. One line of research formulates curriculum planning as a CSP, proposing a planning system based on a constraint-satisfaction approach for constructing valid study plans across multiple semesters [11]. Similarly, process mining approaches can be used to model prerequisite structures and learning pathways to support study planning [5, 10]. Other approaches focus on richer semantic representations of curricula, for instance, based on disciplines, competences, and specialisations [12], or model curricula as prerequisite graphs to support curriculum overview [8] and to verify structural properties such as soundness and the absence of cycles [6].

3. BACKGROUND

The StEOP was initially defined in §66 of the Austrian Universities Act (AUA) of 2002 and underwent significant revisions in the 2015 amendment (BGBI. I Nr. 131/2015). The regulation mandates that all Bachelor's programs, with a few exceptions, must incorporate a StEOP. Its primary goal is to "provide students with an overview of the essential contents of the respective degree program and its further progression, and create an objective basis for making a personal assessment of his or her choice of study" (§66 AUA 2002 (1)). The StEOP must comprise between 8 and 20 credits according to the European Credit Transfer System (ECTS), which have to be completed before students can continue with more advanced courses. An exception are the pre-reg courses, non-StEOP courses students can take up to a certain credit limit before completing the StEOP. By restricting access to advanced courses, the StEOP serves as a regulatory mechanism, imposing a barrier that encourages early completion of foundational courses to engage with the study program's core concepts and expectations at an early stage. At the same time, the pre-reg courses relax the definition by providing some flexibility.

As part of a nationwide analysis in Austria in 2020 [4], standardised indicators were compiled and evaluated to compare the StEOP across eleven institutions. Results showed that 26 % of all enrolled students did not complete any StEOP examinations. Further, among those who started the StEOP, only 47 % completed it within the first semester, and 72 % within two semesters. Still, surveys showed that the StEOP mostly provided a good overview of essential study content, clarified performance expectations, and positively reinforced students' choice of study.

4. AN ILLUSTRATIVE EXAMPLE

To illustrate the structure of StEOP regulations, we consider an example from the Mechanical Engineering (ME) program at TU Wien in 2025. The English translation of the corresponding part of the curriculum definition is given in Figure 1. As shown, the StEOP consists of ten courses organised into groups, accompanied by a natural-language specification that defines the conditions for completing the StEOP: Students must complete twelve credits while meeting various conditions, including completing all mandatory courses and choosing courses from different subgroups. In addition, the curriculum defines a set of pre-reg courses, of which up to 22 credits can be taken.

5. CONCEPTUAL MODEL OF THE STEOP

To derive a formal representation of StEOP regulations, we conducted an exploratory analysis of multiple natural-language descriptions in the official curricular documents. Based on these observations, we first introduce a conceptual model of the StEOP, which we then formalise mathematically and apply to our example.

From analysing several StEOP definitions, we observe that they share the following structural elements:

(1) A set of courses included in the StEOP.
(2) A number of credits to be completed from these courses.

Additionally, they may include some of the following:

(3) A set of mandatory courses.

> As part of the Study Entry and Orientation Phase (StEOP) for the Bachelor's program in Mechanical Engineering (ME) at TU Wien, a total of 12 credits must be completed:
>
> **Mandatory courses:**
>
> 1.0 Introduction to Mechanical Engineering (INTRO)
>
> 2.0 Physics for Mechanical Engineering (PHY)
>
> **Pool 1: Mathematics Fundamentals**
>
> 6.0 Mathematics 1 (MATH)
>
> 3.0 Mathematics 1 Exercises (MATH EX)
>
> **Pool 2: Subject-Specific Fundamentals**
>
> 3.0 Fundamentals of Manufacturing Engineering (MANU)
>
> 3.0 Fundamentals of Business Administration (BA)
>
> 2.0 Technical Drawing / CAD (DRAW)
>
> 3.0 Fundamentals of Design Engineering (DESIGN)
>
> 3.0 Technical Drawing / CAD Exercise (DRAW EX)
>
> 2.0 Mechanics 1 Exercises (MECH EX)
>
> The STEOP is considered successfully completed once both mandatory courses have been passed, and a total of at least 9 credits have been obtained from Pool 1 and Pool 2 combined. At least one course must be selected from each of the two pools. Before completing the StEOP, students may take up to 22 credits of non-StEOP courses from [a list of pre-reg courses].

Figure 1: Description of the StEOP structure in ME.

(4) A subset of courses from which a specified number of credits must be earned.
(5) A subset of courses of which at least one must be completed.

Based on this, we propose modelling the StEOP as a set of *pool rules*. Each pool consists of a *set of courses* and a *minimum number of credits* that must be completed from the set. By combining multiple pool rules (including nested ones) that must all be fulfilled, we can represent all the elements identified above. Elements (1), (2), and (4) are directly captured. A set of mandatory courses (3) can be modelled as a pool in which the required number of credits equals the sum of all courses' credits. Similarly, a subgroup of courses, of which at least one must be completed (5), can be represented as a pool in which at least one credit must be earned. Since courses can only be completed in their entirety, this effectively ensures that at least one full course is completed. In addition to the StEOP course pools, curricula may define a set of pre-reg courses that students can take before completing the StEOP. While this gives students some flexibility, a maximum credit limit applies to pre-reg courses, requiring students to complete the StEOP before taking even more advanced courses.

5.1 Mathematical Formalisation

This conceptual model can be mathematically formalised as follows: Let $\mathcal{C}$ be the universal set of all available courses, where each course $c \in \mathcal{C}$ is represented as a tuple $c = (\mathrm{id}_c, \mathrm{name}_c, \mathrm{cr}_c)$ consisting of a unique course ID, a name, and its corresponding number of credits ($\mathrm{cr}_c \in \mathbb{N}$). Let $\mathcal{X}$ be the set of all available curricula. A specific curriculum $x \in \mathcal{X}$ is defined as a tuple $x = (C_x, S_x, V_x)$ where $C_x \subseteq \mathcal{C}$ is the set of all courses belonging to this specific curriculum.

The StEOP S_x for curriculum x is defined as a set of pool rules:

$$S_x = \{(P_1, k_1), (P_2, k_2), \ldots, (P_n, k_n)\}$$

where each pool $P_i \subseteq C_x$ is a subset of courses, and $k_i \in \mathbb{N}$ specifies the minimum number of credits that must be earned from pool P_i. Let $P_{S_x} = \bigcup_{i=1}^{n} P_i$ denote the set of all StEOP courses across all pools in curriculum x.

The pre-reg rules, $V_x = (W_x, m_x)$, define the additional non-StEOP courses a student may take before completing the StEOP. $W_x \subseteq C_x$ is the set of eligible pre-reg courses and $m_x \in \mathbb{N}$ is the maximum allowed credit limit from those. These courses must not overlap with any StEOP pool:

$$W_x \cap P_{S_x} = \emptyset$$

Let $\mathcal{T}$ be the set of all students. We introduce two boolean predicates: Passed(t, c) evaluates to true if a student $t \in \mathcal{T}$ has successfully completed course c, and Taken(t, c) is true if the student t has already passed or is currently registered for course c. We can now define the predicate Steop(t, x), which indicates whether student t has fulfilled all StEOP requirements for curriculum x:

$$\text{Steop}(t, x) \iff \forall (P_i, k_i) \in S_x : \sum_{\{c \in P_i \mid \text{Passed}(t,c)\}} \text{cr}_c \geq k_i$$

This states that for all pool rules in the StEOP, the sum of the credits of all passed courses within that pool must be at least the defined minimum k_i. From a theoretical perspective, this formalisation can be interpreted as a constraint satisfaction problem (CSP) over sets of courses [2]. Each pool rule corresponds to a constraint on the accumulated credits within the sets, and the StEOP is completed when all constraints are fulfilled.

Further, we can define the predicate CanEnroll(t, c, x), which defines whether a student t can enroll in course $c \in C_x$ within curriculum x as:

$$\text{CanEnroll}(t, c, x) \iff \text{Steop}(t, x) \vee c \in P_{S_x}$$
$$\vee \left(c \in W_x \wedge \sum_{\{c' \in W_x \mid \text{Taken}(t,c')\}} \text{cr}_{c'} + \text{cr}_c \leq m_x \right)$$

This states that a student can enrol in the course if they have already completed the StEOP, the course is part of the StEOP pools, or the course is a pre-reg course, and taking it does not cause the sum of credits of all taken pre-reg courses to exceed the maximum allowed credit limit.

5.2 Applying it to our Example

Applying this model to the ME study program at TU Wien, the StEOP can be modelled using four pools, as shown in Figure 2. The mathematical and subject-specific fundamentals are represented as two pools (each requiring 1 credit), while their combination forms an elective pool requiring 9 credits. The mandatory component is modelled as a pool with a 3-credit requirement, equal to the sum of all included courses. While an overarching pool with a 12-credit requirement could be added, this constraint is already implicitly covered. This formal model precisely maps the textual requirements shown in Figure 1.

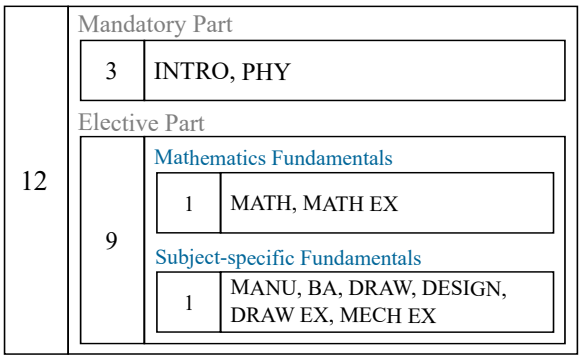

Figure 2: Visualised formalisation of the StEOP in ME.

6. MODEL VALIDATION

To validate the proposed model, we aim to formalise the StEOPs of all curricula at TU Wien respectively. Due to the ambiguity of many pre-reg rules, we focused only on the StEOP rules.

6.1 Semi-Automated Rule Extraction

Since StEOP regulations are provided exclusively in textual form and do not follow a strictly standardised structure, we opted for a semi-automated, interactive extraction approach. First, all relevant curriculum documents (PDFs) are automatically collected from the institution's website. Due to their broadly consistent structure, these documents can be processed uniformly, allowing the StEOP sections to be automatically identified and extracted. The extracted StEOP descriptions are presented to the user in an interactive command-line interface, where the user then encodes the corresponding pool rules through a sequence of simple commands. A pool is created by specifying its name, whether it is mandatory, and the minimum number of credits required. Subsequently, the courses in the pool are entered line by line in a dedicated input mode, including the course name, course type (e.g., lecture or exercise), and number of credits. These course descriptions can often be copied directly from the StEOP description, as they most often follow the same pattern. Lastly, the course names are automatically matched to the corresponding course identifiers. The described semi-automated pool rule extraction process was performed independently by two researchers for all 20 study programs at TU Wien since 2017.

6.2 Results

Across the 20 study programs and their curriculum versions at TU Wien, a total of 46 distinct StEOP regulations were found. Extracting the rules took about two minutes per StEOP. All but one could be fully modelled using the proposed formalisation, achieving a coverage of 98 %. The exception being the StEOP for Computer Engineering from 2023, which contains an elective pool rule that prohibits combining three included courses. Since the proposed formalisation only allows specifying minimum credit requirements, it cannot represent such exclusions. Capturing this rule would require extending the model to include exclusion criteria.

Comparing the extracted pool rules showed that both re-

searchers always identified the same underlying structures. Some differences emerged in naming conventions for pools: one researcher adhered more closely to the terminology used in the official curriculum, while the other preferred a more functional naming scheme. Further, cases in which at least one course from a subgroup has to be completed were sometimes interpreted as requiring the exact minimum number of credits for a course, whereas in other cases they were modelled as a single-course constraint requiring one credit. Similarly, mandatory courses were sometimes additionally included in the elective pool, leading to slight variations in how credit requirements were parameterised. Despite these differences in representation, the resulting models were semantically equivalent and thus equally valid.

During the modelling process, several practical challenges emerged, including missing information (e.g., credit values), underspecified courses, and inconsistencies between course names in the StEOP descriptions and the module handbook. Additionally, some descriptions were inherently ambiguous. For example, the requirement: *"Completion of at least 10.5 credits from the StEOP pool, including at least 3.5 credits from the sub-pool 'Mathematics Basics', and successful completion of the course 'Introduction to Mathematical Work'"* raises the question of whether the latter course is included in the 10.5 credit requirement or must be completed in addition. However, both researchers reached the same conclusion about how to interpret this ambiguity.

A preliminary analysis of the 46 investigated StEOP regulations identified a total of 131 pool rules, of which 43 are mandatory and 88 elective. Each StEOP comprises between one and five pool rules, with most consisting of multiple interacting requirements rather than a single constraint (on average 2.85 pools). Despite this variability, recurring structural patterns can be observed: Four StEOPs consist exclusively of mandatory pools and therefore offer no choice to students, while three consist solely of an unrestricted elective pool, providing maximum flexibility. Ten StEOPs follow a simple structure that combines one mandatory and one elective pool. The most common structure, observed in 20 cases, extends this combination by introducing additional constraints within the elective pool via subpools. These typically require students to complete at least one course from a specific topic area, such as mathematics, or from a particular course type (e.g., lecture or exercise). Furthermore, nine StEOPs combine a mandatory pool with two non-overlapping elective pools. These structures enforce coverage of different subject areas while still allowing individual choice, often balancing subject-specific and foundational or mathematics components. In six of these cases, additional constraints are imposed within the elective pools.

6.3 Discussion

The analysis shows that the pool rule abstraction reliably captures the core structure of StEOP requirements. Only a single special case required an additional constraint that could not be directly modelled with the proposed StEOP formalisation, but which is already addressed by broader curriculum rules. This demonstrates that the proposed formalisation is generally applicable and robust, with the identified exception highlighting a potential extension point for the model without undermining its overall usefulness. Further, the high level of agreement between the two researchers indicates that the proposed modelling approach is robust, even when applied to partially ambiguous curriculum descriptions. While minor differences in naming conventions and modelling decisions were observed, these did not affect the semantic equivalence of the resulting representations.

In addition, the analysis highlights the structural complexity of StEOP regulations. Rather than consisting of a single requirement, most StEOPs comprise multiple interacting constraints, typically combining mandatory and elective components. These are often further restricted by additional conditions, such as selecting at least one course from a specific type or topic area. This structure allows for combining foundational knowledge with some flexibility for individualisation. Although the StEOP regulations are defined independently by different study programs, recurring patterns can be observed, suggesting that they follow implicit design principles.

The formalisation process also revealed challenges. Natural language curriculum descriptions can lack precision, leading to ambiguities in interpretation. While both researchers arrived at semantically equivalent models, some cases allowed multiple plausible interpretations, requiring subjective decisions. This highlights the need for clearer, more standardised, and machine-readable formulations of curriculum rules [9]. While the results demonstrate the general applicability of the proposed model, several limitations remain. The analysis is based on a relatively small sample of 46 StEOP regulations and relies on manual annotation by two researchers, which may limit generalisability. In addition, certain regulatory aspects, such as exemptions due to previously completed courses, are not captured by the current model. Addressing these limitations provides directions for future work. In particular, automating the extraction of the regulations and validating the model against real student data would enable generalisability and allow assessment of how well the formalised rules reflect actual enrolment behaviour. In addition, the proposed formalisation enables several practical applications. For instance, it allows automatically validating whether a planned set of courses satisfies curriculum constraints, thereby supporting study planning tools and reducing invalid course selections. In addition, the model can be used for automated study-planning tools and recommender systems to generate valid study paths under given constraints or to analyse how different curriculum designs affect student progression. By making regulatory structures explicit, it also facilitates their integration into learning analytics systems, where they can be used to contextualise and interpret student behaviour.

7. CONCLUSION

This paper introduces a formal model for representing Study Entry and Orientation Phase (StEOP) regulations as constraint satisfaction problems (CSP), based on nested pool rules over sets of courses with credit-based requirements (RQ1). The model is evaluated on all 46 unique StEOPs at TU Wien since 2017 by applying a semi-automated extraction approach. The results show that all but one analysed regulations can be consistently mapped to the proposed representation, despite being only specified in natural language and lacking standardisation, demonstrating the expressive-

ness of the model (RQ2). Beyond this, the preliminary analysis revealed recurring structural patterns in curriculum design that are not directly visible in the textual descriptions alone, underlining the need for more standardised and transparent curriculum formulations. The presented formalisation of these curriculum rules not only helps identify such patterns and enable their systematic analysis, but it also supports improvements in curriculum design and enables downstream applications, such as study planning tools. Overall, by formalising the StEOP and evaluating its applicability, this work represents a first step toward transforming curriculum regulations into machine-readable artefacts, facilitating their analysis and integration into EdTech. In this way, the proposed approach contributes to more transparent and data-informed support for students, particularly in early study phases.

ABSTRACT

Predicting future student responses to questions is particularly valuable for educational learning platforms where it enables effective interventions. One of the key approaches to do this has been through the use of knowledge tracing (KT) models. These are small, domain-specific, temporal models trained on student question-response data. KT models are optimised for high accuracy on specific educational domains and have fast inference and scalable deployments. The rise of Large Language Models (LLMs) motivates us to ask the following questions: (1) How well can LLMs perform at predicting students' future responses to questions? (2) Are LLMs scalable for this domain? (3) How do LLMs compare to KT models on this domain-specific task? In this paper, we compare multiple LLMs and KT models across predictive performance, deployment cost, and inference speed to answer the above questions. We show that KT models outperform LLMs with respect to accuracy and F1 scores on this domain-specific task. Further, we demonstrate that LLMs are orders of magnitude slower than KT models and cost orders of magnitude more to deploy. This highlights the importance of domain-specific models for education prediction tasks and the fact that current closed source LLMs should not be used as a universal solution for all tasks.

Keywords

Large Language Model (LLM), Knowledge Tracing (KT), Performance, Inference, Deployment Cost

1. INTRODUCTION

Predicting student performance is a fundamental and well studied task in educational data mining. The performance of predictive models has important implications for adaptive learning systems and personalised instruction. In mathematics education, students often exhibit recurring patterns of misunderstanding that lead to predictable errors [1]. If these misconceptions can be anticipated, educators can adapt their instruction and learning platforms can deliver more targeted support. This student misconception identification challenge can be framed as a prediction problem: given a student's response history to past questions, the goal is to forecast their performance on future questions.

Knowledge Tracing (KT) models have been developed specifically to address this challenge [2]. These compact, domain-specific models are trained on student interaction data. They are optimised for high accuracy, fast inference, and scalable deployment. Recent advances include Deep Knowledge Tracing (DKT) [8], which applies recurrent neural networks to model student knowledge states, and Self-Attentive Knowledge Tracing (SAKT) [7], which leverages attention mechanisms to capture dependencies in student response sequences.

The recent success of Large Language Models (LLMs) across diverse tasks, including mathematical reasoning and problem solving [5], raises a natural question: can general-purpose LLMs match or exceed the performance of specialised KT models on student response prediction? This question is particularly relevant given that predicting student performance on mathematics problems requires both reasoning ability and mathematical understanding. It remains unclear whether these LLM capabilities transfer effectively to modelling individual student knowledge states over time. It is also unclear whether LLMs can do so at a cost and speed suitable for real-world deployment.

In this paper, we present a systematic comparison of KT models and LLMs to address three research questions: (1) How well can LLMs predict students' future responses to questions? (2) Are LLMs scalable for this domain in terms of latency and cost? (3) How do LLMs compare to specialised KT models on this task? We evaluate models on a binary classification task, where the model is tasked to predict whether a student will answer correctly or incorrectly. We do this comparison across three dimensions: predictive performance, inference latency, and deployment cost.

Our findings demonstrate that specialised KT models con-

https://doi.org/10.5281/zenodo.21039796

sistently outperform LLMs across all three dimensions. KT models achieve higher accuracy and F1 scores, are orders of magnitude faster (sub-second vs. minutes per student), and cost 600-12,000 times less to deploy at scale. These results highlight the continued importance of domain-specific architectures for educational prediction tasks and caution against adopting general-purpose LLMs as a universal solution in this domain.

2. EXPERIMENTAL PROTOCOL

2.1 Task Formulation

The task we consider in this paper is a binary classification task where the models are tasked with predicting if a student will answer a future question correctly or incorrectly, given their answering history. The models have access to the question text or a question id and the construct text or construct id. This is shown in Table 1. In addition, for each question, we also have misconception text for each possible answer and explanations of the answers demonstrated in Table 2. To avoid cold-start issues for each model we took the decision to not make predictions on the first 10 questions. When predicting the answer to a question the model has access to the student's question-answer history. We decided on a representative load of 100k students requiring 40 answer predictions each to test the models on.

Table 1: Example Question and Construct Data

Component	Example
Question ID	100
Question Text	What is $2 + 3 \times 4$? (A: 20, B: 14, C: 11, D: 26)
Construct ID	10
Construct Text	Order of Operations

Table 2: Example Misconception and Explanation Data

Component	Example
Question Text	6 pencils cost £ 1.50 How much do 3 pencils cost?
Answer Text	0.75p
Misconception Text	Confuses decimal notation in money putting value in pounds but writing the unit for pence
Explanation Text	I think you have used the incorrect notation for money. Consider how the monetary values in the question are written

2.2 Datasets

In Table 3 we detail some statistics about the datasets used throughout this work. The dataset is a real-world dataset extracted from an online learning platform. Notably, the training dataset is only used for the KT models or fine-tuned LLMs. The validation dataset is what is used to report model performance. For all datasets we restricted the number of responses for a student to 50, where the model is only tasked with predicting the final 40 question responses. The dataset bias is the percentage of correct responses. The students in the training and validation datasets are different and student data used to train the model is not used for validation. This means any trained models are being tested for their generalisability to new students. The questions used in the training and validation set are the same; there are less questions in the validation set due to the smaller dataset size and no student in that set having answered some questions.

Table 3: Dataset Statistics

Metric	Train	Val
# Responses	512,000	64,000
# Students	12,800	1,600
# Questions	4,252	4,104
# Responses per student	40.0	40.0
Dataset bias	65.8%	66.5%

2.3 Metrics

The two metrics we use to assess the predictive performance of the models are accuracy and F1 score. Accuracy is the most common metric used to measure model performance in KT model research. It provides an overall value for how often the model is correct and can be used to see if a model is beating the dataset bias. The equation for accuracy is given by

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}. \tag{1}$$

The F1 score can be more valuable than accuracy when a dataset is not balanced, as it considers both how often a model successfully finds correct or incorrect answers via recall, and how often the prediction was correct via precision. In this work we consider a macro-averaged F1 score to assess how well does the perform across both correct and incorrect response prediction. The equation we use for F1 score is given by

$$\text{F1} = \frac{1}{2} \sum_{i=0}^{1} \frac{2TP_i}{2TP_i + FP_i + FN_i}. \tag{2}$$

In both equations TP is the true positives where the model predicted the positive class correctly, TN is the true negatives where the model predicted the negative class correctly, FP is the false positives where the model incorrectly predicted the positive class, FN is the false negatives where the model incorrectly predicted the negative class, and i is the class being considered. Here we deem class 0 as the class of correct responses and class 1 as the class of incorrect responses.

2.4 Models

Deep Knowledge Tracing (DKT) [8] uses question ids and student answering history as model inputs and predicts if a student answers correctly or incorrectly on future questions. Self-Attentive Knowledge Tracing (SAKT) [7] is a self-attention transformer-style model. SAKT similarly uses question ids and student answering history as model inputs and predicts if a student answers correctly or incorrectly on future questions. SemKT is our custom-built encoder-decoder temporal transformer. But this model uses question, construct, explanation, and misconception text as model inputs and uses a Qwen 3 0.6B embedding model to map the text inputs into an embedding space that the KT model uses as an

input. Importantly, we only use Qwen as a feature extractor to obtain fixed vector representations of questions, construct, explanation and misconception text. These embeddings are computed once and cached offline. At inference time, no LLM is involved in the actual student performance prediction. The temporality and modelling of student understanding is handled by our small, custom temporal transformer.

Gemini 2.5 flash lite [3] and GPT 4o mini [6] are both larger closed source LLMs. The specific details of these models are therefore not known but we can estimate their approximate size from online sources. For these models the student history is passed to the model through the input prompt. The input to the LLMs includes question ids, question text, construct ids and construct text. Llama 1B [4] and Qwen 2.5 7B [9] are both open source LLM models. We similarly pass the student history to these models through the input prompt. For Llama 1B LoRA fine-tune we add a small percentage of extra parameters to fine-tune the model for the specific task of predicting students answers to future questions from their answering history. While the KT and LLM models operate on different inputs, they reflect the practical constraints and strengths of each model class.

2.5 Prompting Strategies

For student answer prediction, we employ a constrained prompt design that prioritizes deterministic parsing while providing rich contextual information. Our prompt follows this structure: "The student answered the following questions: Question ID [id] ([question text with choices A/B/C/D]), with construct ID [id] ([construct description]): answered [correctly/incorrectly]... Predict whether the student will answer [new question with full context] correctly or not. Answer ONLY with the word 'Yes' or the word 'No'."

2.6 Testing Setup

The testing of models is split into models that we would deploy ourselves and models that are closed source LLMs that we access via an API. For the models that we access via an API, we report the cost and latency values from using their API. For models that we deploy ourselves, we test the models on a CPU only Azure instance. This instance is a standard DS3 instance that has 4 vcpus and 14GiB of memory. We measure the latency of the model in a deployment setting where the model runs inference on one sample at once, although it should be noted that this could be sped up by increasing the batch size. We calculate the deployment costs based on an hourly rate of $0.27 per hour of the instance.

3. RESULTS AND DISCUSSION

3.1 Model Performance

Accuracy measures the proportion of correct predictions. SemKT achieves the highest accuracy at 72.8%, narrowly outperforming both SAKT [7] (72.7%) and DKT [8] (71.8%), two well-established knowledge tracing models. Interestingly, all domain-specific KT models outperform the general-purpose LLMs like GPT-4o-mini (58.6%), Qwen2.5-7B Instruct (64.6%), and Gemini-2.5-flash-lite (66.5%). We also benchmark two Llama-1B variants: a LoRA fine-tuned Llama-1B (71.0%), while Llama-1B zero-shot performs substantially

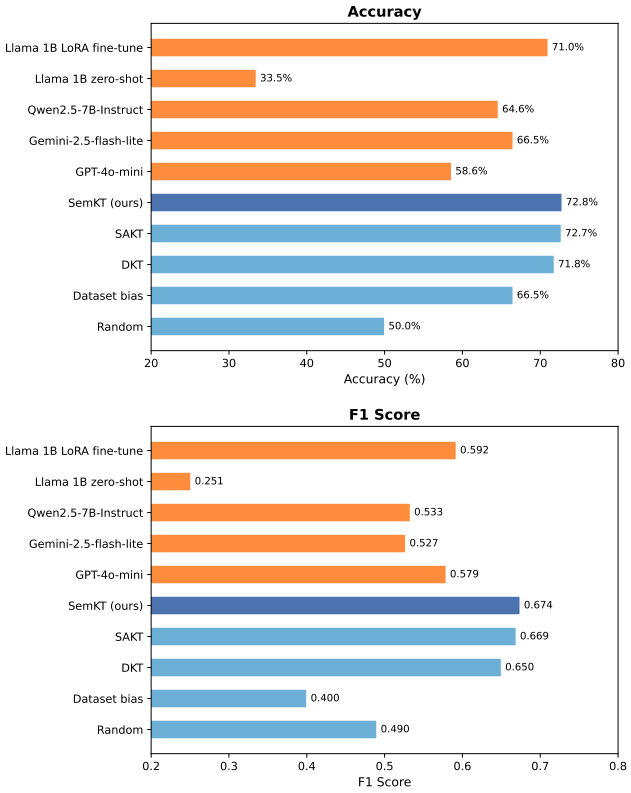

Figure 1: Comparison of model performance.

worse at 33.5%. This reinforces the value of specialised models trained on structured educational data for this task. We refer the reader to Figure 1 for a side-by-side comparison.

For context, we also include a dataset bias baseline that simply predicts the average correctness rate for each question While it does not personalise predictions, it achieves 66.5% accuracy. Notably, several LLMs in our benchmark, despite their billions of parameters, fail to surpass this naive baseline. This makes it a critical baseline any viable model must beat.

Precision measures how often the model is correct when it predicts a student will answer correctly. Recall measures how many of the actually correct answers the model managed to identify. Improving one typically comes at the cost of the other. The F1 score captures this trade-off by combining both into a single measure, rewarding models that perform well on both rather than excelling at one while neglecting the other. The F1 score is therefore more informative when dealing with class imbalance. Once again, SemKT leads with an F1 score of 0.674, followed closely by SAKT (0.669) and DKT (0.650). The LLMs perform lower in this metric as well, with GPT-4o-mini scoring 0.579, Qwen2.5-7B-Instruct 0.533, and Gemini-2.5-flash-lite 0.527. Among the Llama baselines, the Llama-1B LoRA fine-tune improves to 0.592, whereas Llama-1B zero-shot remains low at 0.251. These results affirm that general-purpose LLMs struggle with student-level predictions, likely due to the lack of fine-grained educational supervision.

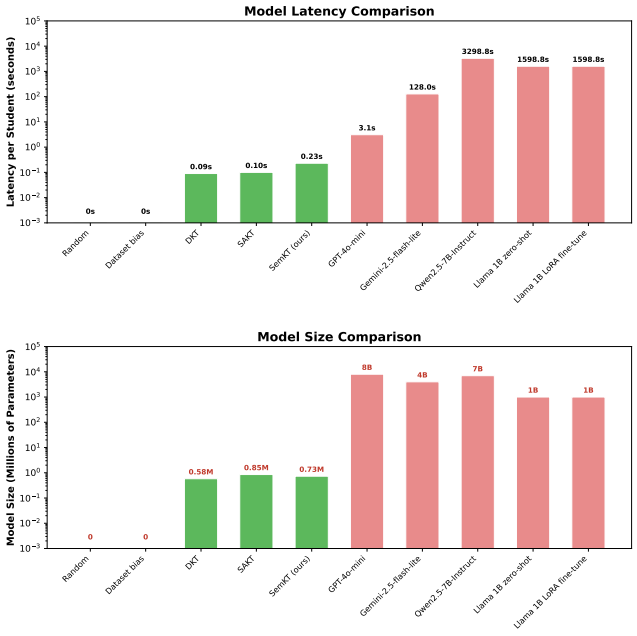

Figure 2: Latency and model size comparison for different models.

The LLMs exhibit different failure modes depending on their design. Llama-1B zero-shot frequently fails to follow the prompt format, producing responses other than the expected 'correct" or 'incorrect," which we treat as incorrect predictions. The remaining LLMs (GPT-4o-mini, Gemini-2.5-flash-lite, and Qwen2.5-7B-Instruct, Llama-1B fine-tuned) adhere to the prompt format but struggle to predict student responses accurately. Notably, despite receiving ten initial question-answer pairs to mitigate cold-start effects, these models fail to infer students tend to get more answers correct in general. In contrast, specialised KT models are trained to leverage such properties of the data, enabling them to make more informed predictions about future student responses.

Our results show that specialised Knowledge Tracing models outperform general-purpose Large Language Models when it comes to predicting student responses. Across both metrics, domain-specific models like our SemKT, SAKT, and DKT consistently deliver stronger performance than smaller LLMs such as GPT-4o-mini, Gemini-2.5-flash-lite, Qwen2.5-7B-Instruct, and Llama-1B. They remain robust even against a fine-tuned small LLM baseline (Llama-1B LoRA). This highlights the importance of task-specific architectures in educational prediction tasks. While LLMs excel at general reasoning, purpose-built KT models remain the most effective and reliable solution for identifying student misconceptions.

3.2 Latency and Model Size

We also compare models on latency (inference time per student) and model size (number of parameters) in Figure 2. These are critical factors for real-time applications and large-scale deployment in educational learning platforms. We note that closed-source LLMs run on different hardware and are accessed via an API.

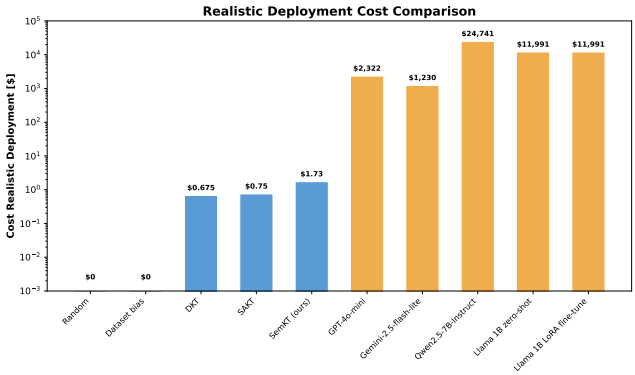

Figure 3: Annual inference cost comparison for 100,000 students receiving 40 predictions per year.

Traditional KT models like DKT, SAKT, and our SemKT deliver fast predictions, with latencies under 0.25 seconds per student. In contrast, LLMs are orders of magnitude slower. GPT-4o-mini takes 3.1 seconds, Gemini-2.5-flash-lite takes 128 seconds, and Qwen2.5-7B-Instruct requires 3,299 seconds per student. Llama-1B variants also take 1,598.8 seconds per student. Despite this latency increase, none of the LLMs outperform the KT models in accuracy.

Specialised KT models are also extremely compact, with model sizes ranging from 0.58M to 0.85M parameters. Our SemKT model contains only 0.73M parameters while offering strong performance. In contrast, general-purpose LLMs are vastly larger: GPT-4o-mini has 8B parameters, Gemini-2.5-flash-lite has 4B, Qwen2.5-7B-Instruct has 7B, and Llama-1B variants have 1B parameters.

This substantial efficiency gap in terms of latency and model size further reinforces that specialised KT models are far better suited for scalable, real-time prediction tasks. This is especially important for deployment in resource-constrained environments, where lightweight prediction models can enable educational tools to reach learners at a global scale.

3.3 Cost Analysis

Cost is a major consideration for real-world deployment at scale, especially for education platforms aiming to support thousands of students. Figure 3 shows the annual inference cost for 100,000 students, each receiving 40 predictions per year. For most LLM models, we benchmarked on 1,600 students with 40 questions each (64,000 predictions) and extrapolated to 100,000 students. For Gemini-2.5-flash-lite, daily rate limits of 10,000 requests per day on Tier-1 restricted us to 200 students, from which we extrapolated accordingly.

Specialised KT models like DKT, SAKT, and our SemKT cost less than $2 per year to serve this workload. In contrast, general-purpose LLMs are vastly more expensive: GPT-4o-mini costs approximately $2,322 per year, Gemini-2.5-flash-lite costs $1,230 per year, Llama-1B variants cost $11,991 per year, and Qwen2.5-7B-Instruct reaches $24,741 per year. This means KT models are 615–12,400 times cheaper than

LLMs for the same task, while also offering higher accuracy. For any large-scale EdTech deployment, this dramatic cost gap makes specialised KT models the better choice.

4. CONCLUSION

Despite the rapid rise of general-purpose LLMs, our findings demonstrate that specialised KT models remain the best choice for predicting student responses in EdTech settings. KT models outperform LLMs (GPT-4o-mini, Gemini-2.5-flash-lite, Llama-1B, and Llama-1B-LoRA-finetune) on accuracy and F1 score, offering better future response predictions. KT models scale to larger numbers of students at a lower cost to EdTech providers due to being over 600 times cheaper to deploy at scale, while offering millisecond-level latency without requiring GPUs. While LLMs excel at broad reasoning tasks, they fall short when applied to student interaction data.

This is not to say LLMs have no place in pedagogical settings; however, they should be employed where they demonstrably reduce costs or improve learning outcomes, not as a default choice. To uncover misconceptions for the greatest number of learners, a scalable, real-time system is required. Currently, purpose-built KT models remain the most effective and practical solution.

ABSTRACT

We present a methodology where LLM coding agents autonomously improve classification prompts for behavioral labeling of educational dialogues. In each iteration, a coding agent analyzes disagreements between classifier output and human labels, then proposes theory-grounded prompt modifications. Applying this to 659 AI tutoring sessions with three agents and three classifiers, 4-fold cross-validation indicated non-trivial gains on held-out data: the best agent improved from baseline $\kappa = 0.70$ to test $\kappa = 0.78$ (SD= 0.12), at \$5–8 per agent in Experiment 2. The process also surfaced undocumented labeling patterns, and continued iteration beyond the optimum led to regression. Iteration logs, prompts, and evaluation scripts are available at: https://github.com/EasonC13/EDM26-Agents.

Keywords

LLM labeling, behavioral analytics, prompt engineering, AI tutoring, educational data mining

1. INTRODUCTION

Understanding student behavior in tutoring dialogues is fundamental to improving educational technology. Detecting patterns such as help-seeking, confusion, and disengagement enables researchers to evaluate tutoring effectiveness and design adaptive interventions [3, 1, 7, 8]. Yet behavioral labeling remains a costly bottleneck: trained coders must manually analyze hundreds of sessions, a process requiring weeks of effort and limiting the scale of educational dialogue research. LLMs offer a promising solution, achieving strong performance on qualitative coding tasks [12, 11]. However, developing effective prompts still relies heavily on researcher trial-and-error over days or weeks.

We present an approach where LLM coding agents serve as *research teammates* that iteratively improve labeling prompts through systematic error analysis. In an exploratory phase, a researcher collaborated with Claude Code over 21 iterations, improving Follow-up Type κ from 0.59 to 0.68 at a cost of \$22 and surfacing a key insight: human coders consistently treated expressions of confusion ("I don't know," "I'm stuck") as engagement rather than disengagement. To validate generalizability, we assigned the same task to three independent coding agents (OpenAI Codex, Claude Code, Gemini), each starting from scratch. On the development set, all three improved substantially, with Codex and Gemini reaching $\kappa = 0.93$. Since iterating on a fixed validation set risks overfitting, our primary evaluation uses 4-fold cross-validation: the best agent achieved held-out test $\kappa = 0.78$ (SD= 0.12), improving over the $\kappa \approx 0.70$ baseline, at \$5–8 per agent. Agents independently converged on similar disambiguation rules, suggesting the methodology identifies genuine patterns. We also tested three classifier models (GPT, Claude, Gemini), finding that same-family advantages manifest as faster convergence rather than higher ceilings in development-set analyses.

Our contributions are a collaborative agent-refinement workflow, held-out evidence of non-trivial generalization gains, an analysis of regression beyond the optimal iteration, and a demonstration that disagreement analysis can surface implicit labeling criteria.

2. METHODOLOGY

Our work builds on help-seeking research in tutoring dialogues [3, 1], LLM-based qualitative coding in education [12, 11, 18, 20], human-in-the-loop educational judgment workflows [13, 2, 9, 10, 17], AI agents in education [5, 4, 6], and automated prompt optimization methods such as APE, DSPy, and OPRO [21, 15, 19]. Unlike metric-only prompt search, our workflow uses coding agents to perform qualitative error analysis and propose theory-grounded revisions under researcher oversight. More specifically, prior work often studies LLMs as collaborators in grading, feedback, or assessment, whereas far less work examines how reliably coding-agent-style systems can autonomously iterate on heuristic rules or prompts for theory-grounded labeling tasks. This distinction matters for educational coding tasks, where prompt changes can improve a metric while weakening pedagogical

interpretation.

A coding agent receives a codebook, human-labeled validation sessions, and an evaluation script. In each iteration, it runs the classifier (temperature= 0), computes Cohen's κ, analyzes disagreements against human consensus, and proposes prompt revisions. The classifier is the model producing labels; the coding agent is responsible for error analysis and prompt revision. The researcher reviews proposed changes to preserve construct validity and pedagogical faithfulness.

We used chatbot interaction data from an undergraduate discrete mathematics course (∼120 students) at a large research university. The course deployed an LLM-powered tutoring system with a "Socratic guardrail": the chatbot used hints and guiding questions rather than direct answers. This setting creates natural behavioral variation, as some students engaged with the scaffolding while others attempted to extract solutions, making the labeling task both challenging and educationally meaningful.

Our dataset comprises 659 sessions collected over two semesters (Fall 2024 and Spring 2025), ranging from brief clarification requests (1–2 exchanges) to extended problem-solving dialogues (20+ exchanges). The median session length was 6 exchanges (IQR: 3–12). Topics spanned logic and propositional reasoning (28%), proof techniques (35%), set theory (22%), and combinatorics (15%). For validation, we randomly sampled 80 sessions stratified by length and topic. Two trained research assistants independently labeled these sessions after two calibration meetings to align on codebook interpretation and edge cases; the first author resolved disagreements through case-by-case discussion, documenting reasoning for each adjudication. This study was approved by our institution's Institutional Review Board (IRB); all student data were collected with informed consent and de-identified prior to analysis.

Drawing on help-seeking theory [1], we defined three labeling dimensions:

- **Student Intent** (Answer-Seeking, Help-Seeking, Other): captures whether the student primarily wants the answer or genuinely seeks to understand.
- **Topic Type** (Conceptual, Procedural): categorizes the mathematical content as definitional or problem-solving.
- **Follow-up Type** (Engage, Escalate, Switch): characterizes the student's response to guidance. Engage includes expressions of confusion ("I don't know"), since admitting confusion signals continued cognitive engagement [14]. Escalate requires an explicit request for direct answers, while Switch indicates topic abandonment.

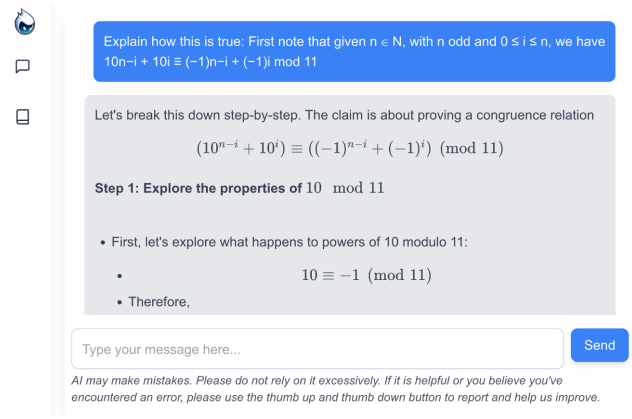

Figure 1: Example tutoring dialogue. Such sessions were labeled for student intent, topic type, and follow-up behavior.

Human coders achieved substantial inter-rater reliability: Intent $\kappa = 0.78$, Topic $\kappa = 0.73$, Follow-up $\kappa = 0.70$ [16]. Overall $\kappa = 0.89$ was computed over composite labels. To avoid mixing metrics, we compare overall model performance only against the human composite $\kappa = 0.89$, and per-dimension results only against the corresponding human kappas.

3. EXPERIMENTS AND RESULTS

3.1 Cross-Agent Validation

To test whether the methodology generalizes across agent architectures, we assigned the labeling task to three independent coding agents: OpenAI Codex, Gemini Code Agent, and Claude Code. Each received identical instructions and access to the codebook, the 80 labeled sessions, and the evaluation script. They worked independently, without access to each other's solutions. All used GPT-5.2 as a classifier for comparability. We kept the classifier fixed because the research question is whether coding agents can improve prompts for a downstream labeling model; using the agent itself as the classifier would conflate prompt-refinement ability with label-generation ability.

Starting from baseline $\kappa \approx 0.70$, after approximately 10 iterations ($5–8 per agent in Experiment 2), all three achieved strong development-set reliability. Table 1 presents the results: Codex and Gemini tied at $\kappa = 0.93$, with Gemini achieving the highest F1 (0.91). Figure 2 shows the progression, including regression when Codex was extended beyond its v7 optimum through v10 (κ dropped to 0.91, with Follow-up Type declining from 0.83 to 0.75), demonstrating that more iterations do not always yield improvement. The hardest dimension was Follow-up Type: across agents, much of the eventual gain came from converging on the rule that confusion expressions should default to Engage unless paired with an explicit request for direct answers.

Table 1: Cross-agent validation results (development set). Best performance shown for each agent.

Agent	Ver.	Overall κ	F1	Intent κ	Topic κ	Follow κ	Cost
Codex	v7	**0.93**	0.88	0.84	**0.85**	0.83	$8
Gemini	v9	**0.93**	**0.91**	**0.85**	0.81	**0.87**	$7
Claude Code	v5	0.91	0.79	0.73	0.78	0.88	$7
Human	–	0.89	–	0.78	0.73	0.70	–

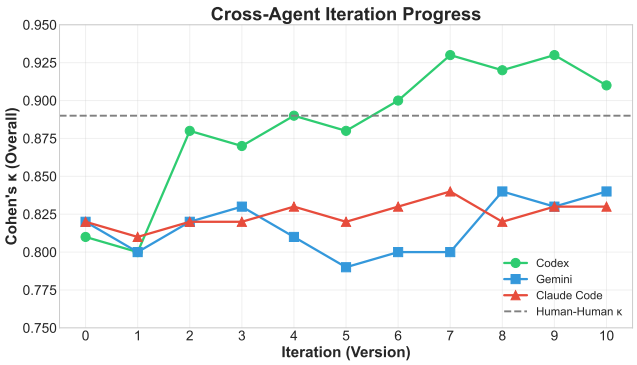

Figure 2: Overall κ progression across iterations. Codex and Gemini both reached $\kappa = 0.93$. Continued iteration led to regression for Codex after v7. Dashed line: human baseline ($\kappa = 0.89$).

Table 2: 4-fold cross-validation results (held-out test κ). Baseline $\kappa \approx 0.70$ for all agents.

Agent	Fold 0	Fold 1	Fold 2	Fold 3	Mean ± SD
Codex	0.85	0.61	0.88	0.79	0.78 ± 0.12
Claude	0.71	0.81	0.84	0.66	0.76 ± 0.08
Gemini	0.71	0.67	0.88	0.63	0.72 ± 0.11

Despite working independently, agents converged on similar disambiguation rules: (1) Switch reserved for truly unrelated topics; (2) Escalate requires explicit answer requests; (3) Engage as default for continued dialogue, including expressions of confusion. This independent convergence across three architectures suggests the methodology identifies genuine patterns rather than agent-specific artifacts.

3.2 Cross-Validation

Because all three agents iterated on the same 80 sessions, strong development-set performance may reflect overfitting. To assess generalization, we conducted a 4-fold cross-validation, splitting the 80 sessions into four folds of 20 sessions each, stratified by intent distribution. We chose 4-fold rather than 10-fold because with three multi-class dimensions, 8-session folds risk zero instances of rare categories (e.g., Switch), making κ estimation unreliable. For each fold, agents developed prompts using 60 training sessions and evaluated on 20 held-out sessions (113 total iterations across all agent-fold combinations).

Table 2 reveals substantial overfitting: Codex dropped from development $\kappa = 0.93$ to test 0.78; Claude from 0.91 to 0.76; Gemini from 0.93 to 0.72 ($\Delta\kappa \approx 0.15$–$0.21$). Nevertheless, the methodology shows improvement over baseline: all agents improved from baseline test $\kappa \approx 0.70$ to 0.72–0.78 on held-out data. The best result (Codex, $\kappa = 0.78$, SD= 0.12) remains below human composite agreement ($\kappa = 0.89$), so the held-out result should be interpreted as a meaningful gain over baseline rather than as surpassing human overall agreement. Variance across folds (SD= 0.08–0.12) reflects sensitivity to fold composition given the small validation pool.

Table 3: Best development-set κ across classifiers.

Agent	GPT	Claude	Gemini
Codex	0.93	0.93	0.87
Claude Code	0.91	0.91	0.89
Gemini	0.93	0.85	0.92

3.3 Classifier Effects

We also explored whether a "same-family advantage" exists when agent and classifier share the same model architecture. These comparisons are descriptive development-set analyses rather than held-out cross-validation results. Same-family pairings generally converged faster, but did not consistently produce higher ceilings. For example, Gemini Agent reached $\kappa = 0.92$ by v5 with Gemini but required v9 to reach 0.93 with GPT, while Codex reached 0.93 with both GPT and Claude but showed smoother convergence with GPT. Overall, classifier choice appears to matter more for iteration dynamics than for the final peak achieved on the development set.

4. DISCUSSION AND CONCLUSION

Convergent solutions and tacit knowledge. The most striking finding is independent convergence across Codex, Claude Code, and Gemini. Despite different model families, all three agents moved toward similar disambiguation rules, especially around the treatment of confusion expressions. The key rule, "confusion = engagement," was absent from the original codebook and emerged through systematic human-AI disagreement analysis, aligning with productive failure theory [14]. This suggests that the agent workflow can do more than optimize prompts: it can help surface tacit labeling criteria that researchers already apply but have not yet articulated explicitly.

Iteration dynamics and stopping rules. Continued iteration beyond the optimum can hurt performance through overcorrection or output instability. In practical terms, once an agent reaches strong agreement, additional rules may introduce new errors while fixing only a handful of old ones. Our results therefore support a simple stopping principle:

use held-out validation to select the best prompt version rather than assuming the latest version is the best. This is a straightforward methodological recommendation for prompt-engineering research that has often been missing from prior educational coding work.

What the classifier comparison suggests. The classifier comparison adds a more tentative point. Same-family pairings did not consistently yield higher final peaks, but they often converged faster. That pattern suggests that model family may matter more for the efficiency and stability of iteration than for the final achievable performance. Because these analyses remain development-set only, we treat them as exploratory.

Practical implications for educational research. From an applied perspective, the workflow lowers the cost of rigorous dialogue coding. Each agent required only $5–8 for roughly ten iterations, and the total researcher effort remained modest compared with traditional multi-coder training and calibration. The gains are not large enough to claim that agents replace human agreement, but they are meaningful enough to support hybrid workflows in which agents accelerate prompt refinement, expose edge cases, and reduce the manual burden of theory-grounded labeling.

Prompt strategies and why they mattered. A useful secondary observation is that not all prompt-revision styles behaved the same way. The strongest prompts tended to make category boundaries explicit through ordered decision rules, especially for the hardest dimension, Follow-up Type. In contrast, more heuristic prompt language left greater interpretive burden on the downstream classifier. This matters for educational dialogue coding because the task often hinges on subtle distinctions such as confusion versus disengagement, or productive help-seeking versus answer-seeking. Our results therefore suggest that for nuanced theory-grounded coding tasks, agents are most helpful when they distill tacit qualitative judgments into concrete disambiguation rules rather than merely adding more examples or longer prose.

Recommendations for future users of this workflow. Two practical recommendations follow. First, researchers should begin with a compact prompt derived directly from a codebook, then let the agent target the weakest dimension rather than modifying all dimensions at once. Second, they should save richer artifacts than we did here: fold assignments, selected prompt versions, and per-dimension held-out outputs. Doing so would make later audit, replication, and paper writing much easier.

What the remaining errors suggest. Our error analysis also points toward concrete future directions for educational dialogue research. Remaining disagreements clustered into four recurring patterns: ambiguous intent, context-dependent interpretation, multi-turn dynamics, and rare interaction patterns. Some were cases of genuinely ambiguous intent, where even human coders disagreed before adjudication. Others reflected context dependence across turns, where the same phrase could signal productive confusion in one exchange and frustration in another. These patterns suggest that future systems may benefit from richer representations than single-label session coding alone, such as turn-level coding, uncertainty-aware labeling, or multi-label treatments for borderline cases. In that sense, the present workflow is useful not only for prompt optimization but also for diagnosing where the current coding ontology itself begins to strain.

Why human oversight remains important. One lesson from the full iteration history is that higher agreement alone is not always enough. Some prompt changes initially looked attractive because they improved a subset of cases, but they did so by blurring theoretically meaningful distinctions. Human review therefore remains central, not as a bottleneck to eliminate, but as the mechanism that keeps the refinement process aligned with pedagogical constructs rather than with metric chasing alone.

Limitations. The study also has clear limitations. The 80-session validation set limits statistical power and creates overfitting risk, and we did not retain fold-level per-dimension held-out artifacts or full fold metadata in the current supplementary release. Thus, our preserved held-out evidence is stronger for overall composite performance than for dimension-specific generalization. Because fold sizes are small, we treat differences between agents and classifiers descriptively rather than as statistically significant. Cross-validation also provides a held-out estimate within the 80-session pool, not a completely untouched final test set from the broader 659-session corpus. We also relied on commercial models and coding-agent frameworks, which limits exact reproducibility despite releasing prompts, logs, and evaluation scripts. We did not compare against fine-tuned models, and session-level classification cannot capture within-session intent shifts. Finally, although the coding scheme transfers conceptually to other tutoring contexts, some decision rules are domain-shaped by mathematical dialogue and would likely need adaptation in writing, science, or language-learning settings.

Why this matters methodologically. Prompt engineering for educational coding should be documented as a process rather than reported only as a final prompt plus a final score.

Overall, the results suggest that LLM coding agents can act as collaborative partners in codebook development, yielding held-out gains and useful stopping rules.

The agent's iteration logs, prompts, and evaluation scripts are available at: https://github.com/EasonC13/EDM26-Agents.

Identifying Learning Progression Profiles in a Psychomotor Task Using Sequence Clustering

Emily Jensen
Franklin & Marshall College
ejensen@fandm.edu

ABSTRACT

Psychomotor skill learning remains underexplored in educational data mining, which has historically focused on cognitive tasks. Understanding how learners progress toward mastery over time, rather than simply measuring final outcomes, is essential for designing adaptive instructional systems. In this work, we analyze trial-by-trial learning progressions from a simulated drone landing task. Participants completed 20 trials with performance categorized as crash, unsafe landing, or safe landing. We compute transition probabilities between performance categories and apply a k-medians clustering algorithm using Levenshtein distance to identify representative learning sequences. Transition results show that learners rarely make large performance jumps between consecutive trials and tend to maintain safe landings once achieved, consistent with our knowledge of motor skill acquisition. Clustering reveals meaningful learner profiles ranging from quick mastery to persistent struggle, with finer-grained distinctions emerging as the number of clusters increases. These findings provide an initial foundation for developing feedback and task selection policies in intelligent tutoring systems that are sensitive to a learner's trajectory through skill acquisition, not only their current performance state.

Keywords

psychomotor skill, clustering, sequence analysis, learner profile

1. INTRODUCTION

Educational data mining research has largely focused on cognitive tasks such as problem-solving and knowledge acquisition. However, many real-world learning domains require the development of psychomotor skill combining cognitive reasoning and motor control. The unique dynamics of these tasks make them both harder to measure and harder to model than discrete knowledge states.

Aggregate measures of learning such as final accuracy or learning gain neglect to consider the path a learner took to get there. Two learners with identical final performance may have followed very different trajectories. Additionally, progress in skill acquisition is rarely monotonic; we often see plateaus, regressions, and bursts of improvement. Identifying common trajectory types moves emphasis from "did they learn?" toward "how did they learn?". This approach is necessary for designing feedback that responds to a learner's progression rather than their current performance snapshot alone.

Adaptive feedback systems are most effective when they can anticipate a learner's near-future state or respond to long-term misconceptions rather than simply react to their last action. If distinct learner subgroups follow recognizably different paths through skill acquisition, feedback policies can be tailored to each pathway. This work takes a step toward data-driven feedback policy design by starting to understand the landscape of learning trajectories, laying the groundwork for eventually optimizing feedback to nudge learners toward more favorable pathways. In this work, we apply sequential analysis methods to explore typical learning progressions in a drone landing simulation, which offers a controlled learning environment with rich trial-by-trial performance data.

2. RELATED WORK

Research in intelligent tutoring systems has a rich history of using performance data to inform interventions and develop personalized analytics. In particular, Bayesian Knowledge Tracing models and variants use transition probabilities to represent how learners acquire knowledge over time [1, 14, 15, 18]. These models infer mastery based on previous estimates and the learner's most recent performance. This approach to learner modeling acknowledges that learning is not a linear process and performance can fluctuate for a variety of reasons.

Additionally, learning and education data are well-suited for sequential analysis [21]. Sequential pattern mining tools have often been used to connect behavior patterns with learning outcomes [7, 11, 16], provide better interventions [4], or understand higher-level reasoning skills [2, 10]. Some work has started to use sequential analysis to understand learning trajectories [13], though this is not well studied for psychomotor tasks.

Recent work has also considered how identifying learner profiles can help inform recommendations and personalized

learning paths [9, 17]. These are often applied to large-scale learning environments such as MOOCs and use features such as demographics and engagement metrics. More work is needed to understand how common sequences of learning performance can be used to shape feedback, especially for complex tasks.

3. APPROACH

3.1 Dataset

The data was collected in a previous study [5], but all analyses presented here are new. The study was approved by the local ethics board and all data are anonymized.

In an online study conducted through Prolific, participants completed 20 trials of a computer-based drone landing simulation [3] (see Figure 1). Participants were placed into one of three feedback conditions to improve their performance. The final set of participants is evenly split between feedback conditions, though the conditions are not explicitly considered in this work. We only consider data from those who completed all 20 trials, resulting in a final set of 166 participants.

The main measure of interest is participant performance on each of the 20 trials. In alignment with previous work [19, 20], landing performance was assigned to one of the ordinal labels *crash*, *unsafe*, or *safe*. A trial was labeled as safe if the participant landed the drone in the target area with a landing speed ≤ 15 m/s and a landing angle $\leq 5°$. Unsafe landings violated at least one of the landing speed or landing angle constraints. Finally, attempts that did not reach the landing pad were labeled as a crash. This approach yielded 3,320 total performance labels across all participants. Participants demonstrated mastery of the task by consistently achieving safe landings. Figure 2 shows the distribution of landing performance across trials.

We encoded the learning progression of each participant as a sequence of 20 "words" from a fixed vocabulary (i.e., landing performance category for each trial). These sequences were represented by a string of characters, with the characters C, U, S corresponding to *crash*, *unsafe*, or *safe*. An example sequence from a participant achieving only safe and unsafe landings is SUSUUUSSSSSUUUSSUSUS.

3.2 Analysis Methods

We first calculated the transition probabilities for the landing performance categories. These probabilities show how participants improve or regress in their performance between trials. Each value represents the likelihood of moving between two categories in consecutive trials. The transition matrix is normalized across rows, meaning the destination probabilities for each starting category sum to 1.

To identify representative learning progressions, we implemented a variant on the k-means clustering algorithm [12]. To calculate the distance between learning progression sequences, we used the Levenshtein edit distance [8]. Instead of calculating a numeric mean as the center of each cluster, we calculated the approximate generalized median string of all data points in a given cluster using the Levenshtein Python library (https://pypi.org/project/python-Levenshtein/). To assess the quality of each cluster, we calculated the average within-cluster Levenshtein edit distance, where more similar sequences have a smaller edit distance.

Given no established value for the expected number of learning progression profiles, we used the elbow method across multiple values of k. For each number of clusters k, we calculated the average quality across all clusters and reported the best across 10 restarts.

4. RESULTS

The transition probabilities show how learners improve their performance between trials. Figure 3 shows the highest probability in the safe→safe case, showing that learners are generally able to maintain consistent performance once they understand a task (nearly 70% of the time). There are also strong probabilities on the diagonal, where participants maintained their performance level between tasks. The superdiagonal of the matrix includes the next highest set of probabilities; these are the cases where participants jumped to the next performance level between trials. Similarly, the subdiagonal represents the cases where participants regress a level between trials, though these probabilities are notably smaller.

The transition matrix also shows it is unlikely to achieve large changes in performance between trials, either in the crash→safe condition or the safe→crash condition. In the context of a Bayesian Knowledge Tracing model of student performance, these conditions may relate to low "slip" and "guess" probabilities where learner performance is misaligned with their inherent mastery of the task.

Figure 4 shows how cluster quality changes over a range of k values. We did not find a clear elbow; rather, the average edit distance across clusters steadily across the entire range. This suggests that adding more clusters will continue to identify more specific profiles, or a more nuanced evaluation metric is needed. Using a smaller number of clusters for designing feedback policies makes practical sense, since clusters will be more distinct and easier to interpret.

Table 1 shows detailed clustering results for $k \in \{2, \ldots, 5\}$. Given the results of the elbow analysis above and in the interest of interpretability, we do not report results for higher values of k.

In the $k = 2$ condition, the centers represent the profile of a struggling learner and one who quickly masters the task.

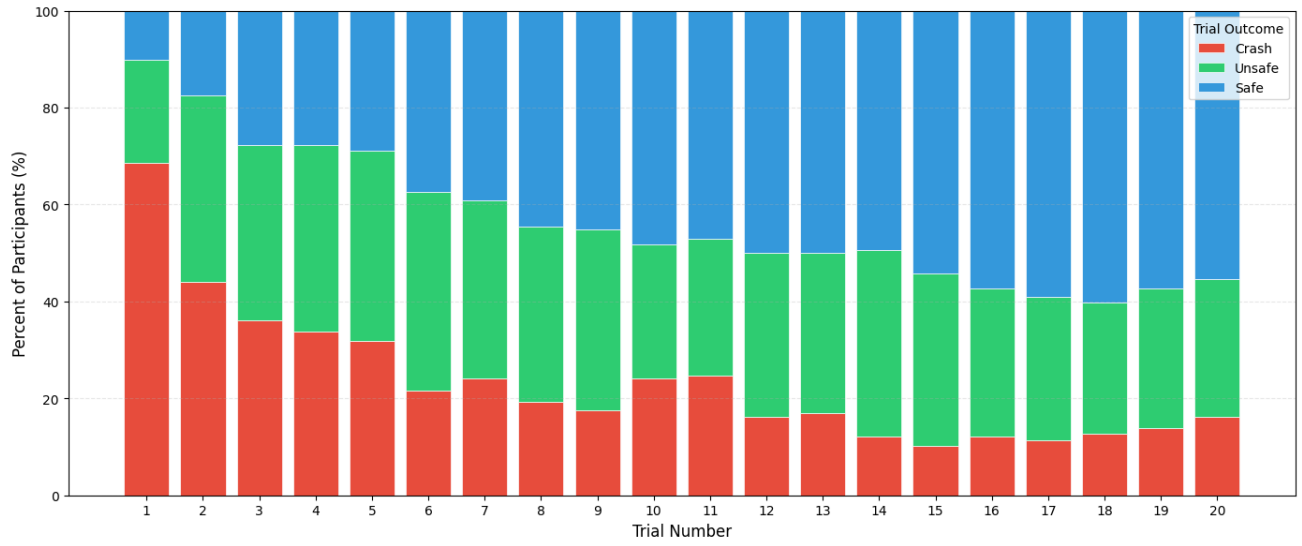

Figure 2: Distribution of landing outcomes for each of 20 trials. Participants achieve more safe landings as the trials progress.

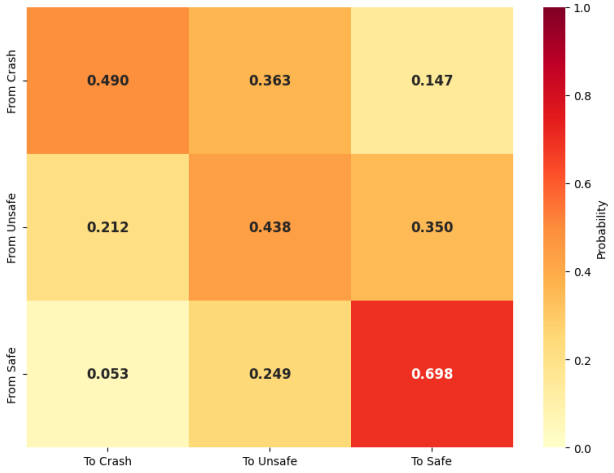

Figure 3: Transition matrix showing the probabilities of changing performance categories between trials. Darker cells have higher probabilities.

		CCCCCCCCCCCCCCCCCCCCC

The profile of the struggling learner sees a majority of crash and unsafe landing outcomes, with a few safe landings towards the end of the trials. The quick learner shows a few crashes and unsafe landings at the beginning, quickly converging to consistent safe landings.

The other models show similar patterns. In the $k = 3$ condition, the profiles represent participants quick to master the task, those who consistently achieve unsafe landings, and those who may struggle to understand the control dynamics and crash most trials. The $k = 4$ condition adds another proficient learner that takes a bit longer to get comfortable with safe landings. Finally, the $k = 5$ condition adds a profile that achieves a few safe landings at the end, though they may need more practice to become consistent. These results show that clustering can identify meaningful learning progressions, with more clusters leading to more nuanced profiles that may be useful for detailed feedback development.

5. DISCUSSION

This study examined learning progression in a psychomotor drone landing task, finding that sequence clustering can uncover meaningful learner profiles from trial-by-trial performance data. The transition matrix results confirm that learners rarely make large jumps in performance between consecutive trials, and that once safe landings are achieved they tend to be maintained. This pattern is consistent with the consolidation dynamics characteristic of motor skill acquisition. Together, these results suggest that the ordinal performance encoding used here captures structure in the learning process.

The clustering results show that even a small number of profiles can meaningfully identify different types of learners. Even with two clusters, the model separates quick learners from those who struggle to achieve safe landings. Additional clusters reveal finer distinctions, such as learners who plateau at unsafe landings versus those who crash consistently. The absence of a clear elbow is itself informative; it suggests learner profiles may exist on a continuum rather than falling into a small number of clear types.

6. FUTURE WORK

The current work developed profiles of learning progression only using the final landing performance outcome for each trial. Future work can investigate how learner control inputs (e.g., joystick movements, button presses) can be used to understand the learning process and develop feedback. This can take inspiration from previous work focused on cognitive tasks [6].

Future work should also consider how these profiles of learning progression relate to the feedback conditions in the original experiment. Rather than evaluating personalized interventions based on static measures such as number of safe landings, applying sequence analysis to each condition separately may give a more detailed understanding of how feedback can shape a learner's mastery of a task over time.

Investigating Patterns of Iterative Code Changes in the VEXcode VR environment by Combining Heuristic Patterns with Hidden Markov Modeling

Hyeongjo Kim, Luc Paquette, Jennie Lee
University of Illinois at Urbana-Champaign
{hk61, lpaq, jl294}@illinois.edu

ABSTRACT

Computational problem solving (CPS) is a core component of computational thinking and is increasingly supported through game-based learning environments. However, understanding learners' problem-solving processes in such environments remains challenging especially when they engage students in open-ended problem-solving with no unique solution pathway. In this study, we examine learners' CPS processes in VEXcode VR, a block-based robotics programming environment, by investigating iterative code modification behaviors. Drawing on in situ observations, we first identified three heuristic problem-solving patterns: step-by-step, relying on fortune, and strategy change. These patterns were operationalized using a code change score and modeled using a categorical Hidden Markov Model (HMM), enabling the representation of latent problem-solving states and their temporal dynamics. The results demonstrate strong alignment between the latent states inferred by the HMM and the heuristic patterns identified by researchers, supporting both the validity and interpretability of the model. The interpretations of the identified patterns highlight the importance of considering the unique modality of game-based environments when understanding learners' computational problem-solving processes.

1. INTRODUCTION

Computational problem solving (CPS) is recognized as a core competency in contemporary education, particularly in technology-rich and game-based learning environments [2]. CPS involves a set of cognitive processes, including problem formulation, algorithmic thinking, iterative testing, and debugging, through which learners construct and refine solutions to complex problems [10]. To support CPS, game-based learning (GBL) has been used as scaffolding for computational problem solving through providing immediate and continuous feedback, reducing cognitive load, and simulating real-world systems [2, 9, 10].

Because both games and coding fundamentally involve problem solving [2], prior studies examining problem-solving patterns in game-based learning provide useful conceptual frameworks for understanding CPS. However, as Matcha and colleagues [5] noted, students' strategic behaviors can vary across learning environments even when guided by the same theoretical framework, largely due to differences in modality. For example, while systematic evaluation is often considered a more advanced and desirable strategy than trial-and-error in traditional problem-solving contexts [4, 7], repeated cycles of trial and error are not merely preliminary strategies but can constitute a core process of solution development, testing, and debugging in CPS contexts [2, 8]. Therefore, in CPS environments, examining how learners iteratively modify their code during trial-and-error processes provides a direct and meaningful way to understand their problem-solving strategies.

Therefore, in this study, we investigate the CPS processes of students using VEXcode VR, a block-based programming environment in which students must program a robot to perform different tasks. Tasks generally do not have one unique solution and may involve randomness which impacts the final outcome of executing a solution. More specifically, we examine how learners iteratively modify their solutions in the VEXcode VR environment and explore how these iterative changes can be modeled to reflect different problem-solving processes. Insights about the students' code change behaviors were obtained through in-situ observations and review of screen-capture video to identify three heuristic problem-solving patterns (step-by-step, relying on fortune, and strategy change) which were modeled using a categorical Hidden Markov Model (HMM), enabling us to capture CPS processes in a game-based learning context while accounting for its unique affordances.

2. COMPUTATIONAL PROBLEM SOLVING IN GAME-BASED LEARNING

Computational problem solving (CPS) refers to a logical and abstract reasoning process for addressing problems, involving understanding a problem, devising a solution plan, and evaluating outcomes through programmed procedures [2, 10]. CPS is considered a core component of computational thinking (CT), reflecting the centrality of problem solving in CT definitions. To support CPS and CT, a learning-by-doing approach has been widely adopted as a constructionist alternative to direct instruction [2, 6]. While this approach aligns with the exploratory nature of CPS, it poses challenges for novice learners who often lack sufficient knowledge and skills in both computation and problem solving to effectively address ill-structured problems [3]. As a result, learners may struggle to engage productively without appropriate guidance.

To address this gap, research has emphasized the importance of scaffolding, particularly through game-based learning (GBL) environments. Games provide several affordances that support CPS. First, they enhance motivation by offering immediate and continuous feedback during problem solving [1]. Second, games sometimes employ designs to reduce cognitive load such as block-based or card-based coding interfaces, allowing learners to focus on the logical structure of solutions without being hindered by syntax and semantic errors [2]. Third, games enable simulations of complex real-world systems, such as space or physical laws, thereby situating problem solving within meaningful and interactive contexts [1, 2].

Beyond these affordances, both games and CPS fundamentally center on problem solving [2]. In game environments, players either attempt to solve predefined challenges or construct their own goals in open-ended contexts, utilizing available resources within the system. In CPS contexts, these resources correspond to programming systems and interfaces, which serve as tools for constructing and testing computational solutions. This structural alignment suggests that GBL environments function not only as motivational tools but also as spaces where CPS processes are actively enacted.

Based on this alignment, studies have proposed integrated frameworks that connect CPS processes in GBL environments [2, 8]. They commonly include identifying problems, designing and developing solutions, testing and debugging the solutions. Each stage is associated with specific CT practices [8]. For example, in the identifying problem stage, learners engage in decomposition, abstraction, and generalization to break down and simplify problems. These stages provide a structured lens for understanding CPS, but understanding how learners enact these processes in practice has led researchers to examine learners' behaviors through log data.

Previous studies have examined learners' problem-solving processes through log data to reveal how they develop and test solutions. For example, in Zoombinis, a mathematics problem-solving game, researchers have identified structured problem-solving processes and investigated how specific behaviors correspond to different stages, as well as how these behaviors can be modeled to represent sequential progress and strategies [4, 7]. Although the identified strategies such as trial-and-error and systematic testing in problem solving are also relevant to CPS, their roles may differ depending on the learning context. Matcha and colleagues [5] demonstrated that students' strategic behaviors can vary across learning environments even when guided by the same theoretical framework, largely due to differences in modality. CPS environments present a distinctive modality in which learners construct solutions through code and iteratively test and revise them. In the context of Zoombinis, systematic evaluation is often considered a more advanced and desirable strategy than trial-and-error, and transitions from trial-and-error to systematic evaluation are treated as indicators of improved problem-solving competence [4, 7]. In contrast, within CPS contexts, repeated cycles of trial and error are not merely preliminary strategies but constitute a core process of solution development, testing, and debugging [2, 8]. Therefore, in CPS environments, examining how learners iteratively modify their code during trial-and-error processes provides a more direct and meaningful way to understand their problem-solving processes and strategies.

3. CONTEXT

3.1 VEXcode VR

The study was conducted using the VEX Robotics programming environment, specifically VEXcode VR, a block-based platform designed to foster computational thinking and problem-solving skills. Within this environment, learners control a virtual robot by creating sequences of commands, including movement, rotation, and control structures, to navigate simulated spaces. The system provides immediate visual feedback through simulation, enabling students to iteratively test, debug, and improve their solutions. Our study employed a custom-made version of VEXcode VR which automatically logged all student interactions, such as code creation and execution, supporting fine-grained analysis of learners' problem-solving processes over time.

The study was conducted across three different playgrounds (simulated 3 dimensional spaces), each presenting distinct problem-solving goals. In Coral Reef Cleanup, students programmed a robot to collect and remove trash in an underwater environment within limited battery constraints, emphasizing efficient navigation and resource management. In Castle Crasher, learners developed programs to knock down castle structures and transport debris into designated areas, requiring strategic planning. In Rover Rescue, goal prioritization was highlighted as students programmed a rover with the goal to maximize mission duration through three strategy choices: collecting minerals, neutralizing enemies, and returning minerals to base. . After executing each code, the system assigns a score based on predefined rules (e.g., the amount of trash collected) that involve randomness, meaning that an identical code could yield different outcomes. Across all playgrounds, tasks were open-ended, allowing multiple solution paths and encouraging iterative refinement.

3.2 Data

A total of 18 students participated in a one-and-a-half-hour session per day over three days. Students played on one playground each day in the following order: Coral Reef Cleanup – Castle Crasher - Rover Rescue. Each day, students first received a brief introduction to the environment and core programming commands before engaging in individual coding activities. During each session, learners iteratively developed and executed their programs, receiving immediate feedback from the simulation and refining their solutions accordingly. While collaboration and discussions were allowed, each student constructed their own solution. Instructors helped students mostly when they were asked by students. Throughout the process, all programming actions and execution events were logged, enabling the analysis of learners' iterative problem-solving behaviors over time.

Two types of data were collected for this study: screen capture recordings and programming log data. Screen capture recordings without sounds were obtained during participants' interactions with the VEXcode VR programming environment. In addition, detailed coding logs were automatically recorded. These logs include various user actions, such as adding, editing, and moving blocks, as well as executing programs (e.g., "Run project"). All interaction data were stored in JSON format, enabling fine-grained analysis of learners' computational problem-solving processes over time. The Institutional Review Board (IRB) at University of Illinois Urbana-Champaign reviewed the data collection protocol and made the determination that it did not meet criteria for "human-subject research" since all collected data was fully anonymized with no identifier linking the data to participants.

4. MODELING ITERATIVE CODE CHANGES

The modeling process integrated human insights with data-driven analysis to identify patterns of iterative code changes in VEXcode VR. First, in situ observations and reviews of screen-capture recordings of problem-solving activities were used to identify meaningful code-change patterns while accounting for contextual factors and the environment's unique modality. Then, we defined how these patterns could be operationalized using the VEXcode VR interaction log data. Finally, a Hidden Markov Model (HMM) was fit to categorize student problem-solving interactions as one of three identified code change patterns.

4.1 In situ Observations

Learners' behavioral patterns were heuristically identified by two researchers (first and third authors) who participated in the camp as facilitators and had direct experience observing and interacting with learners during the activities. Drawing on their domain knowledge and in situ experiences, they collaboratively articulated patterns they perceived in students' iterative code-change processes.

Screen capture recordings were revisited as needed to refine these interpretations. However, this study did not employ systematic video coding procedures, as the primary goal of this phase was not to generate exhaustive behavioral coding, but rather to elicit and formalize contextual understandings of learner behaviors. Through this process, we identified three overarching patterns that were consistently observed across the three playgrounds: step-by-step, relying on fortune, and strategy change.

The step-by-step pattern is characterized by students making small, incremental changes to their code, executing it, and then modifying it based on the last state of the VEX robot in each execution.

The relying on fortune pattern is characterized by repeated execution of the same code without any modification. Unlike typical iterative testing where code is refined between runs, students repeatedly run an identical program in an attempt to obtain better outcomes. This behavior is closely related to the design of the VEXcode VR environment, where stochastic elements can produce different outcomes. For example, the Coral Reef Cleanup playground randomizes when and where pieces of trash fall into the playground, whereas in the Castle Crasher playground, physics simulations determine how the castle structure reacts to collisions with the robot, which can result in greatly differing outcomes when repeatedly executing the same program.

Within this context, students appear to rely on randomness to achieve higher scores rather than refining their code. This pattern often emerged after a period of step-by-step iteration. It may reflect a temporary shift in strategy, such as taking a cognitive break, exploring outcome variability, or attempting to maximize performance from existing solutions. After several repetitions, students typically returned to modifying their code.

The strategy change pattern involves substantial revisions to the structure of the code, including modifying or removing large portions of previously constructed solutions. Compared to the other patterns, this behavior was observed relatively infrequently. We observed that students were generally reluctant to abandon or significantly alter existing code, which may explain the rarity of this pattern. Although we observed instances of strategy change, it was uncertain from our observation what constitutes an appropriate threshold for distinguishing it from incremental (step-by-step) modifications.

4.2 Operationalization of Identified Patterns

The patterns we heuristically identified were used as an initial foundation for pattern recognition, serving as a rough yet meaningful basis for subsequent systematic analysis. Operationalizing these patterns through a data-driven approach enables the development of models grounded in empirical evidence. To operationalize these patterns, it was necessary to translate them into quantifiable representations. As the identified patterns primarily relate to how students modify their code across program execution, we computed a code change score to capture the degree of difference between consecutive code submissions.

We computed the code change score by combining a position-weighted change rate with a length-based adjustment. First, differences between two consecutive code sequences were evaluated at each sequential position. A binary change indicator was assigned for each position, taking the value of 1 if the blocks differed (or if one sequence was shorter), and 0 otherwise. To reflect the structural importance of earlier code segments, we applied an exponentially decaying weight to each position, giving higher importance to changes occurring at the beginning of the sequence. The weighted changes were then normalized by the sum of positional weights to obtain a position-weighted change rate.

To account for the overall size of the program, this rate was further adjusted using a length-based weight (square root). Finally, the code change score was computed as the product of the position-weighted change rate and the normalized length weight, resulting in a measure that captures both the structural impact and the extent of code modifications. This formulation allows the score to reflect both the structural significance of changes (via positional weighting; $e^{-position}$) and the magnitude of edits (via length adjustment; $\sqrt{length}$).

An initial examination of the distribution of code change scores suggested the presence of distinct behavioral tendencies (Figure 1). The histogram revealed a substantial proportion of zero-change cases, along with a concentration of small changes and relatively fewer large changes. Specifically, over 40% of the observations showed no change in code, and even when changes occurred, they were typically minimal. This distribution provides preliminary support for the existence of the three heuristic patterns: minimal or no change (relying on fortune), incremental change (step-by-step), and substantial change (strategy change).

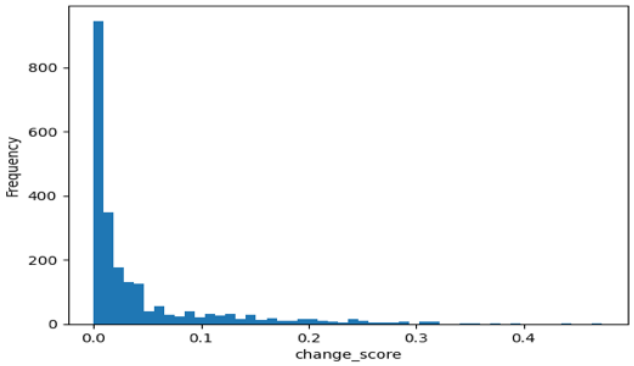

Figure 1. Distribution of code change scores across consecutive submissions.

Importantly, our observations emphasized that individual code change values should not be interpreted in isolation. Rather, patterns emerge over sequences of actions. For example, a sequence consisting predominantly of no-change trials with a single instance

of code modification would still be interpreted as relying on fortune, rather than as a mixture of patterns. This highlights a limitation of approaches that rely solely on observed transitions, such as Markov chains.

To address this limitation, we adopt Hidden Markov Modeling (HMM), which enables patterns to be conceptualized as hidden states that generate observable behaviors (i.e., code changes). From this perspective, the code change score serves as an observable indicator, while the underlying problem-solving patterns are inferred as hidden states. By modeling temporal sequences in this way, HMM provides a more nuanced representation of learner behaviors, consistent with instructors' interpretations.

To align with the heuristic categories and facilitate interpretation of the HMM results, we constrained the model by discretizing the continuous variable into categorical states and employing a categorical HMM instead of a continuous HMM. Code change scores were discretized into three levels: no change (0), small change (below the 95th percentile), and large change (above the 95th percentile). The 95th percentile corresponds to substantial modifications affecting a large portion of the code; in practice, these cases typically involve changes to more than 85% of blocks when the program contains at least 10 blocks, indicating a clear restructuring of the program.

4.3 Categorical Hidden Markov Modeling

Each student's interaction sequence was represented as a series of discrete observations derived from code changes categories between consecutive runs. Using the operationalization described in Section 4.2, each action was categorized into one of three observable types: no change, small change, and large change.

The HMM assumes that the observed sequence is generated from an underlying sequence of latent states, where transitions between states follow a first-order Markov process. Emission probabilities represent the likelihood of observing each type of code change given a latent state. Researchers should set the number of hidden states while the hyperparameter can be decided by comparing various models with different numbers of hidden states. However, this study first sets the number of hidden states at three to implement the heuristic patterns we observed.

When fitting the model, to address the issue of local optima due to random initialization, each model was trained with 100 random restarts, and the solution with the highest log-likelihood was selected. This procedure also allows us to assess the robustness of the identified patterns and reduce the likelihood of reporting coincidental results. The result shows that the average consistency across the 100 restarts is 84%, indicating robustness. We averaged the emission and transition probabilities to set the final model (Table 1).

Table 1. Emission and Transition Table for HMM model.

Emission			
Hidden state	No change	Small change	Large change
0	0.13	0.86	0.00
1	0.25	0.59	0.15
2	0.82	0.17	0.00
Transition			
0	0.94	0.00	0.04
1	0.03	0.91	0.05
2	0.09	0.05	0.84

Inspection of the emission probabilities enabled interpretation of the latent states in terms of observable behaviors. One latent state was characterized by a high probability of no change, corresponding to the relying on fortune pattern. Another state predominantly emitted small changes, aligning with the step-by-step pattern. The third state was associated with large changes, reflecting the strategy change pattern. Importantly, this state was not limited to large code modifications alone; it also included small adjustments following major changes, as well as immediate re-execution without modification. These results demonstrate that the latent states inferred by the HMM correspond closely to the heuristic patterns articulated by researchers.

After implementing our heuristic model into the HMM, we examine whether the model can be expanded and elaborated by relaxing the constraints we imposed for HMM. To determine the optimal number of hidden states, we fitted models with two to five states and evaluated them using the Bayesian Information Criterion (BIC) and Akaike Information Criterion (AIC). The results were as follows: 2 states (AIC = 3136.84, BIC = 3176.82), 3 states (3064.28, 3144.23), 4 states (3031.67, 3163.01), and 5 states (3034.39, 3228.55). BIC was minimized at three states, whereas AIC favored a four-state model. These results suggest that additional patterns may emerge by relaxing the constraints of the HMM, such as increasing the number of hidden states or modeling the code change score as a continuous variable rather than a categorical one.

5. DISCUSSION AND CONCLUSION

This study aimed to understand computational problem solving (CPS) processes in VEXcode VR, a game-based learning (GBL) environment, by examining how learners iteratively engage in testing and revision across trials using a code change score. Three dominant CPS patterns were identified in this environment: step-by-step, relying on fortune, and strategy change. These patterns reflect both general problem-solving strategies and the unique affordances of coding in a game-based context.

The step-by-step pattern reflects how learners in VEXcode VR construct partial solutions, test them, and incrementally refine their code. This behavior is closely tied to the environment, which allows a code to be executed and evaluated at intermediate stages, thereby providing built-in scaffolding for iterative development.

The relying on fortune pattern highlights game-specific characteristics. Due to stochastic elements, identical code executions can yield different outcomes, leading learners to repeatedly run the same code to achieve better results. While step-by-step reflects formative, incremental refinement, relying on fortune resembles summative evaluation under varying conditions without immediate modification. These patterns are also shaped by the ill-structured nature of the problem space. With no single correct solution and evaluation based on relative performance (e.g., scores), learners must interpret feedback and make decisions under uncertainty.

The strategy change patterns are consistent with general problem-solving process. This represents a substantial shift in approach, involving major modifications or entirely new solutions, and aligns more closely with general problem-solving processes than with game-specific mechanics.

Taken together, our findings show how the specific characteristics of the VEXcode VR environment, such as stochastic playground outcomes, executable intermediate states, and ill-structured tasks, shaped the way learners develop strategies. This aligns with Matcha and colleagues [5], which highlights that different learning modalities can give rise to distinct strategies even under the same

theoretical framework. For example, while the observation of step-by-step and strategy change patterns aligned with common CPS processes, the strategy of relying on fortune appeared to be unique to VEXcode VR, where the repeated execution of the same program may produce different outcomes. This underscores the importance of understanding the unique modalities of both CPS and game-based environments when analyzing and interpreting learners' behaviors.

However, several limitations should be addressed in future research. First, the sample size of 18 participants limits the generalizability of the findings. Therefore, future studies should include larger and more diverse datasets. Second, the identified heuristic patterns require further validation through methods such as systematic video coding and inter-rater reliability analysis. Third, the use of the 95% threshold for defining strategy change should be theoretically justified rather than relying solely on a data-driven criterion. Finally, to determine whether these patterns are educationally meaningful, future research should examine their relationships with learning outcomes such as task performance, code efficiency, and learning gains.

ABSTRACT

Effective adaptive instruction depends on knowing what a student has mastered and what they are ready to learn next. Traditional scale scores, such as those obtained from item response (IRT) models, provide only limited support for this purpose. Consequently, several recent approaches conduct student assessment within hierarchical structures of test items or competencies. While these approaches are theoretically promising, practically applicable methods for identifying such structures from empirical data remain scarce, particularly in the presence of missing item responses. To address this gap, this contribution introduces MCAR-IITA— a new implementation of Inductive Item Tree Analysis (IITA) that provides three variants of handling missing responses. To evaluate its performance, the following research question was addressed: At what percentage of missing responses can the proposed variants still recover the underlying structure? Response data were simulated along a true structure under two conditions: 1) without noise and 2) with noise, using fixed careless errors and guessing probabilities of .20 per item. Missing responses were introduced incrementally across conditions, and performance was assessed in terms of the proportion of missing data up to which the true structure could still be recovered. Additionally, the same procedure was applied to a subset of the PISA 2003 dataset based on a previously identified structure. For each dataset, the three variants were evaluated using 1,000 replications. On average, the algorithm recovered the underlying structure with a missing response percentage of 28.47% (SD = 4.49pp) for the error-free simulation, 19.93% (SD = 4.44pp) for the simulation with noise, and 15.41% (SD = 4.65pp) for the PISA data. As this study examines a first implementation and is restricted to a limited set of conditions, the results provide an initial estimate of missing-data tolerance while highlighting substantial opportunities for further optimization.

1. INTRODUCTION

Tailoring instruction to students' current states of learning requires fine-grained information about both their mastered skills and their next feasible learning opportunities. Since traditional scale scores, such as those obtained from Item Response Theory (IRT) models, provide only limited support for this purpose, novel statistical frameworks that employ hierarchical structures have been developed (e.g., DBN [7], HCDM [13], KST [5]). While these approaches are theoretically promising and some methods and software exist that make their application feasible in certain contexts, successful applications remain limited and further development is needed to expand their range of use.

In this contribution, Inductive Item Tree Analysis (IITA) [15], which is one of the primary methods for establishing hierarchical structures from response data, will be introduced briefly, followed by an illustration of its use in educational assessment using Knowledge Space Theory (KST) [5] as an example. Afterward, MCAR-IITA—a new software implementation of IITA that provides three different versions of missing response handling—will be presented. The performance of this implementation with different proportions of missing data will be evaluated in a simulation study.

2. THEORETICAL BACKGROUND

IITA is a method of Boolean analysis used to derive hierarchical structures among items. The IITA algorithm takes a table of Boolean values as an input. Each column represents an item, e.g. a problem from a test or a question in a survey, and each row represents a student. Each value in the table shows if the subject represented by the row solved the item represented by the column correctly (1) or incorrectly (0). In this study, the algorithm will be discussed in the context of items within competence tests.

The output of the algorithm is a binary relation on a set of items Q, represented by ordered pairs of the form $a \leq b$ for $a, b \in Q$. The relation $a \leq b$ on the set of items Q indicates that mastering item a is a prerequisite for mastering item b. Since from the mastery of item b, the mastery of item a can be surmised, this relation is called

surmise relation. It forms a quasi-order among the items of Q, i.e. it is assumed to be reflexive, $(\forall a \in Q: a \leq a)$, and transitive, $(\forall a, \mathrm{b}, \mathrm{c} \in Q: (\mathrm{a} \leq b \wedge b \leq \mathrm{c}) \Rightarrow b \leq c)$.

The surmise relation might be viewed as a theoretical model of the cognitive organization of knowledge in a given item domain and, as such, constitutes a latent construct, that is not directly observable from data. In practice, measurement errors introduce a probabilistic discrepancy between the latent surmise relation and the manifest response patterns, making it impossible to directly infer relationships from observed data. Therefore, the IITA algorithm aims to inductively derive the quasi-order that best fits the observed response data, thereby reconstructing the latent surmise relation from empirical observations.

These quasi-orders find direct application in educational assessment, most notably in KST, which is the basis of the commercial assessment platform ALEKS [1] and is considered one of the most efficient frameworks for adaptive instruction [6]. Unlike traditional psychometric approaches—both classical test theory and IRT—KST does not attempt to compute a numerical score representing a learner's proficiency level. Instead, the goal of assessment is to provide a precise description of what a learner knows and does not know at a given moment [5].

Student assessment in KST is based on a hierarchical structure. Let Q denote a nonempty, finite set of items (or problems) that can be formulated within a particular topic-domain. In KST, a learner's knowledge is represented by a subset $K \subseteq Q$ containing exactly those items that the learner is capable of solving.

Not all subsets of Q necessarily are knowledge states. Logical and pedagogical dependencies among items impose constraints on which subsets are practically possible. One way of modeling these dependencies is by establishing a surmise relation on Q.

The collection of all knowledge states existing in a population of learners is called a knowledge structure, formally defined as a pair $(\mathrm{Q}, \mathcal{K})$, where $\mathcal{K} \subseteq 2^Q$ is a family of subsets of Q containing at least the empty set $\emptyset$ (representing a learner who has mastered none of the items) and Q itself (representing a learner who has mastered all items). A knowledge structure $(Q, \mathcal{K})$ is called a knowledge space if $\mathcal{K}$ is closed under set union. Every knowledge structure induced by a surmise relation is a knowledge space.

Even though new data-driven methods for building general knowledge structures have been developed IITA remains the only procedure capable of extracting a quasi-order from the data [3] and can thus still be considered as the standard [12]. The quasi-order resulting from IITA can be directly translated into the basis of a knowledge space. As an example, consider the quasi-order represented by the ordered pairs $(I1, I2)$, $(I1, I3)$, $(I1, I4)$, $(I1, I5)$, $(I2, I3)$, $(I2, I4)$, $(I2, I5)$, $(I3, I4)$, $(I3, I5)$. The surmise relation can be visualized in an incidence matrix (see Table 1).

Table 1. Surmise relation as binary incidence matrix

Item	I1	I2	I3	I4	I5
I1	1	1	1	1	1
I2	0	1	1	1	1
I3	0	0	1	1	1
I4	0	0	0	1	0
I5	0	0	0	0	1

The basis of a knowledge space, which is the minimal set of knowledge states K from which all other knowledge states can be derived by set union, can be constructed by transposing the incidence matrix. The knowledge states K are the rows of the resulting matrix. The corresponding knowledge space is the union closure of the knowledge states from the basis. It can be visualized through a directed acyclic graph (see Figure 1).

Despite the benefits of KST and its close connection with IITA, current software implementations of IITA lack practical applicability mainly due to restrictive assumptions on the input response data. IITA and its predecessor Item Tree Analysis (ITA) [16] have publicly accessible implementations in R and Python. While there is an ITA version in the R package pks, IITA can be found in the R package DAKS [14] and the Python package kst available from Milan Segedinac. Importantly, all implementations require binary datasets without missing data.

Missing data constitutes a longstanding and well-known challenge in statistical inference, particularly with respect to decisions on how missing responses should be treated in data analysis [2]. Even under carefully controlled data collection procedures, missing responses

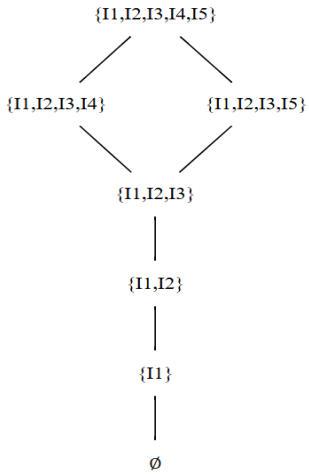

Figure 1. Knowledge space

frequently occur for a variety of reasons. In educational assessment contexts, such reasons include a lack of knowledge about an item, accidental skipping, time constraints during test completion, or design-related factors such as adaptive testing procedures. Moreover, many large-scale educational studies deliberately employ test designs in which each participant is administered only a subset of a substantially larger item pool. Such matrix sampling or booklet designs, as used for example in the PISA study, induce a large proportion of structurally missing responses by design rather than by student behavior. Consequently, missing data is not an exceptional phenomenon but rather an inherent characteristic of empirical educational data, especially in large-scale and computer-based assessments.

One of the first researchers to provide a systematic framework for addressing missing data mechanisms was Rubin [9]. He emphasized that decisions about the treatment of missing data should not be made without explicitly considering the process that generated the missingness. To formalize this idea, a complete dataset Y_{com} be a tuple $Y_{com} = (Y_{obs}, Y_{miss})$ of observed data and missing data. Furthermore, let U be a missingness indicator specifying which responses are observed and which are missing.

Within this framework, Rubin distinguished three fundamental missing data mechanisms. Data are said to be missing completely at random (MCAR) if the probability of missingness is independent of both observed and unobserved data, that is, $P(U|Y_{com}) = P(U)$.

A less restrictive mechanism is missing at random (MAR), where missingness may depend on observed data but not on the missing responses themselves, formally $P(U|Y_{com}) = P(U|Y_{obs})$.

Finally, data are missing not at random (MNAR) if the probability of missingness depends directly on the unobserved values Y_{mis}.

While missing response handling has been thoroughly studied within IRT [8], it has not played a critical role in KST literature. Even though models for parameter estimation based on incomplete data have been developed within KST [4], the construction of the knowledge structure from data with missing responses has not yet been addressed.

Against this background, the present contribution introduces MCAR-IITA—a new implementation of IITA with three different variants of handling missing responses—assuming that missingness is completely at random (MCAR). Its performance was initially evaluated by addressing the following research question: At what percentage of missing data can the proposed IITA variants recover the true structure from response data?

3. THE MISSING-COMPLETELY-AT-RANDOM IITA (MCAR-IITA)

In this section, the three variants of the new implementation of IITA for handling missing responses are presented. Python code for the implementation and the subsequently reported simulation study can be found at the following link: https://anonymous.4open.science/r/iita_python_testing/.

The implementation is developed following the three steps of IITA outlined in the Theoretical Background. In the first step, the number of counterexamples for each item pair is calculated. In the second step, an array of inductively generated quasi-orders is output, which are evaluated regarding their fit in the third step.

For handling missing values, our implementation primarily adapts the first step of the IITA procedure. We provide three variants for this step, of which the first (*IITA-ABS*) serves as default. This default variant ignores missing responses entirely when counting counterexamples, proceeding only with the observed responses for each item pair. A potential limitation of the IITA-ABS variant arises from the fact that the original IITA algorithm counts counterexamples in absolute numbers rather than proportions. In the context of complete datasets this approach is unproblematic, since all item pairs are observed with equal frequency across respondents. However, when missing responses are distributed unevenly across items, this assumption no longer holds. The second variant (*IITA-REL*) accounts for the issue described above by dividing the absolute number of counterexamples by the number of cases where a counterexample can appear (i.e., where neither response is missing) for every item pair. Thereby, a relative counterexample counter with values between 0 and 1 is obtained. In the third variant (*IITA-IMP*), the missing responses are first imputed by the item-mean imputation, replacing each missing value with the mean of the available responses of the respective item. Afterwards the counterexamples are calculated as in the second variant.

4. SIMULATION STUDY

To evaluate the IITA implementation and its three variants of missing data handling, a simulation study was conducted.

4.1 Methods

As in previous studies about the performance of IITA [10, 15], we used the *pisa* dataset from the DAKS package, which contains the item responses by 340 German students on a five-item dichotomously scored mathematical literacy test. This dataset will be referred to as *pisa-orig*. Applying IITA to this dataset results in the surmise relation depicted in Table 1. Since it is real world data, the relation among the items is naturally latent. Accounting for that fact, additional data was simulated along this structure. The resulting datasets *pisa-sim-0-0* and *pisa-sim-2-2* also contain 340 response patterns to five items. While *pisa-sim-0-0* was simulated with zero noise such as careless errors and lucky guesses, thereby containing only knowledge states as response patterns, the dataset *pisa-sim-2-2* was simulated with a probability of .20 for guessing and careless errors. Originally all three datasets do not contain any missing responses.

The quasi-order, identified originally from the *pisa-orig* dataset was taken as the true underlying structure for all three datasets. To test the percentage of missing data that the three different variants of the implementation can handle, missing responses were inductively added at random positions via a data amputation procedure [11]. Therefore, in every iteration, possible positions for missing responses in the dataset are identified. A position is possible, if there is no missing value already and if neither a column nor a row is completely empty after adding the missing value. From the pool of possible positions, two are chosen randomly. The data at these positions of all three datasets are replaced by missing responses. After introducing the missing responses, all variants are applied to all three datasets. The quasi-order extracted by each variant is compared with the true quasi-order. If one variant produces a different quasi-order from one of the datasets, it is not applied to that dataset again in the next iteration. The procedure ends if no variant produces the correct quasi-order on any of the datasets anymore. This was repeated for 1,000 iterations to account for positional differences in the missing responses. The data were descriptively analyzed by calculating the means and standard deviations for each dataset-variant combination.

4.2 Results

As illustrated in Figure 2, the true partial order was extracted up to a missing data proportion of 21.22% (SD = 7.29pp) on average

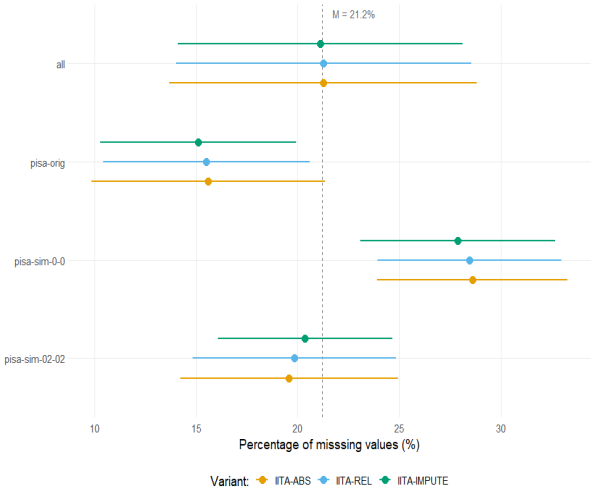

Figure 2. Comparison of average missing value percentage across the different datasets and different variants

across all three variants and datasets. For the real-world dataset *pisa-orig*, all three variants performed on average worse than on the synthetic ones, with an average missing data proportion of 15.41%

(SD = 4.65pp). The best-performing variant on this dataset was IITA-ABS with an average tolerance of 15.6% (SD = 5.75pp) of missing data.

As expected, on the two synthetic datasets all three variants performed better on the noiseless dataset *pisa-sim-0-0*. The average missing data coverage on this dataset across all three variants is 28.31% (SD = 4.49pp). The ranking across the three variants is the same as on the *pisa-orig* dataset: the IITA-ABS performs best (M = 28.6, SD = 4.68pp), the IITA-REL performs slightly worse (M = 28.47, SD = 4.53pp) and the IITA-IMP performs worst (M = 27.88, SD = 4.79pp).

Interestingly, the picture changes when considering the *pisa-sim-2-2* dataset, where careless errors and lucky guesses were introduced with a noise probability of .20. On average, a tolerance for missing data of 19.93% (SD = 4.44pp) was achieved across all three variants, with IITA-IMP performing best (M = 20.37%, SD = 4.31pp). The IITA-REL variant performed slightly worse (M = 19.84%, SD = 5.01pp), while IITA-ABS—previously the best-performing variant on the other two datasets—performed worst on this dataset (M = 19.58%, SD = 5.35pp).

4.3 Discussion

The results demonstrate the capability of the MCAR-IITA implementation of handling missing data. Particularly compared to other psychometric methods, an average tolerance for missing data of 21.22% can be considered substantial [2]. Overall, all three IITA variants perform similarly, showing a good tolerance for missing data on the simulated datasets (about 20%) as well as on the real dataset (about 15%).

These findings should be interpreted in light of several limitations. First, the study design accounted only for the factor of missing value positions within the dataset. In further studies more factors like the size of the dataset and domain characteristics like the amount of pairwise relations should be included.

Furthermore, while MCAR-IITA is theoretically able to handle all MAR-data, this study evaluates only the performance on MCAR data, which represents the least complex case of missingness. While future research should continue to investigate this special case, given that it enables the application of IITA to a broad range of large-scale assessment data with multi matrix designs, examining MAR and MNAR mechanisms would also be of practical value.

Lastly, it should be noted that the proportion of missing responses at which the implementation ceases to recover the correct structure provides only an initial insight into algorithmic performance and precludes further informative analyses. For instance, if the algorithms had continued to run after outputting a non-exact structure, their behavior could have been analyzed with respect to the difference between the recovered and the true partial order.

Beyond refining the simulation study design to better understand the interaction of IITA with missing responses, several other avenues for future research warrant consideration. While the implementation presented has already yielded promising results, there is still room for improvement. Especially, since mainly the first phase of IITA was adapted to suit datasets with missing values, manipulating the fit metrics at the third step could yield further optimization potential.

5. CONCLUSION

Inductive Item Tree Analysis constitutes one of the foundational methods for enabling state-of-the-art formative student assessment. However, its practical applicability has been constrained by restrictions on the input data. In particular, handling missing responses remains one of the most pressing challenges, as they occur in the vast majority of empirical datasets. This contribution introduced and evaluated MCAR-IITA—an IITA implementation incorporating three distinct variants for handling missing responses. The results are promising, demonstrating that the implementation can recover underlying item structures even in the presence of substantial proportions of missing values (i.e., up to about 20%). Beyond these findings, this work opens a variety of avenues for further investigation, both with respect to the implementation presented here and regarding additional algorithmic optimizations. Thus, this contribution represents an important step toward making state-of-the-art psychometric methods more broadly applicable in educational practice.

ABSTRACT

Gender bias in machine learning models can perpetuate and amplify existing societal inequalities, especially in domains where the users are vulnerable such as in education. In this study, we measure the effectiveness of multiple preprocessing unfairness mitigation strategies to reduce gender bias in predictive models trained on student data. Furthermore, we investigate how these mitigation techniques influence the underlying feature representations of the data, yielding insights into the procedural mechanisms by which bias is reduced. Through a series of experiments using four education datasets, we improved fairness and found that some methods dramatically modify data more than others. Using a diverse set of fairness metrics and statistical divergence methods, such as Wasserstein distance, we observe that the level of data modification and the level of bias reduction are not strongly related. To further isolate the role of data transformation, we additionally analyze mitigation methods that induce comparable levels of feature-level data modification, enabling more controlled comparisons across techniques. These results provide an initial analysis into the complexity of the unfairness mitigation step for educational modeling.

Keywords

Algorithmic fairness, Unfairness mitigation, Data transformation, Grade prediction

1. INTRODUCTION

Researchers and educators have harnessed big data mining techniques as a powerful way to leverage increasing quantities of educational data to improve learning outcomes, personalize education, and support diverse groups of students [6, 10]. One common tool that leads to these benefits is predictive modeling, which has proven useful in tasks such as grade prediction, mastery prediction, course recommendation, and dropout prevention [2, 29, 20]. However, as predictive models become more influential in educational decision-making, concerns about the fairness of these models have grown. Bias in educational data can perpetuate inequalities and even undermine the potential benefits of educational data mining methods [33, 24, 7]. Addressing these biases is critical to ensuring that predictive models do not exacerbate existing disparities in educational systems.

Education researchers have already begun to mitigate and understand bias in machine learning-powered educational systems [43]. While there has been varying success in applying unfairness mitigation techniques, there has been limited exploration of how preprocessing-based unfairness mitigation methods transform data in unexpected or opaque ways [19, 13]. Understanding these data transformations is important, as they can have downstream effects on model performance, interpretability, and fairness.

In this paper, we evaluate multiple preprocessing unfairness mitigation strategies across four educational datasets using a standardized data-transformation pipeline. Beyond measuring overall fairness improvements, we analyze how these mitigation techniques influence feature-level data representations. Rather than relying on a single divergence measure, we assess mitigation effectiveness using multiple fairness metrics, allowing for a more comprehensive evaluation of bias reduction. In addition, we compare mitigation methods that induce similar levels of feature-level data modification, enabling more controlled comparisons that disentangle the effects of the mitigation mechanism from the extent of data transformation itself. Thus, we examine how different preprocessing unfairness mitigation techniques can alter educational data and how the transformations influence the fairness and utility of grade prediction models. Our analysis is shaped by the following research questions:

Research Question 1 (RQ1): Are preprocessing unfairness mitigation strategies applicable in reducing gender bias in grade prediction?

Research Question 2 (RQ2): How can preprocessing unfairness mitigation strategies differentially impact student data?

We answer RQ1 by analyzing how four preprocessing unfairness mitigation algorithms can reduce gender bias in four education datasets. To answer RQ2, we analyze if the amount of transformation is linked to the level of bias mitigated.

The preliminary results in this paper extend beyond tech-

nical aspects of applying unfairness mitigation to grade-prediction. Through uncovering how preprocessing techniques differentially transform student data, the research helps to better understand the tradeoffs between unfairness mitigation and data integrity. That is, modifying the data could result in procedural unfairness if the resulting data represents students in unexpected, inaccurate, or otherwise undesirable ways [33, 36]. Thus, we hope to help education researchers in deciding how to implement unfairness mitigation techniques into transparent educational systems.

2. BACKGROUND

Machine learning pipelines in educational data mining often result in some type of prediction or learner model with the goal of improving student learning. These models are often used to predict a student's risk of dropping out [39, 1, 25], whether a learner has mastered certain topics in learning sessions [16, 29], grades on exams [3, 40, 17, 30], to name a few applications. As these predictive models are applied into classroom and online settings, concerns about the biases within these models have become increasingly examined [5, 23, 35]. To address the biases in the models, researchers in education and related fields have developed techniques to mitigate and measure the biases in the development of the models [19, 38, 37]. These techniques are often grouped into categories based on which step in a machine learning pipeline that act on. Preprocessing techniques transform the dataset used to train machine learning models [15, 22, 44]. Inprocessing techniques add other steps and parameters to the training process of models [41, 31]. Postprocessing techniques edit the predictions of the models [32, 28].

Researchers in education have already begun to test the utility of different unfairness mitigation techniques. In fact, educators have cared about issues of bias and fairness for decades [21]. Recently, researchers have developed techniques specific for educational data [38, 15, 8], examined how these techniques impact the data themselves [33], and surveyed how these algorithmic fairness issues should be handled in education [4, 14]. In this paper, we contribute to this research by examining if certain preprocessing unfairness mitigation techniques are useful at mitigating gender bias in grade prediction. Furthermore, we examine if there is a relationship between the gender bias mitigated and the amount that preprocessing techniques distort educational data, which is essential to understand for situations where such data distortion is undesirable.

3. METHOD

In the following section, we detail the datasets and experimental design. For RQ1, we evaluate whether preprocessing unfairness mitigation strategies reduce gender bias in grade prediction by comparing models trained on original datasets to models trained on mitigated datasets. For RQ2, we quantify the magnitude of data transformation introduced by each mitigation technique and analyze whether greater data modification corresponds to greater bias reduction in the trained models.

3.1 Data

We use four student performance datasets covering diverse age groups for prediction tasks. For all datasets, we frame the problem as a binary classification task, with student gender as the sensitive attribute. Gender is treated as a binary sensitive feature in our analyses since we are following the terminology used in the datasets. Other potentially sensitive attributes are removed prior to analysis (we note that unfairness can also exist between intersectional groups, but for our preliminary analysis we focus on one demographic all the datasets share). Table 1 includes the base rates and demographics of the datasets.

Table 1: Base rates of gender across datasets

Dataset	Gender	No. Obs	Pass (%)
HAR	Man	301	21.93
	Woman	413	17.92
POR	Man	266	64.29
	Woman	383	73.37
MAT	Man	187	56.68
	Woman	208	49.52
HSP	Man	87	48.28
	Woman	58	25.86

Harvard Student Performance Data (HAR): The HAR dataset is used to predict final grades in a Physics course. HAR contains 21 categorical and numerical features for 714 students. The 21 features consist of academic information and individual differences.

Student Portuguese and Math Performance Data (POR, MAT): The POR dataset predicts final grades in a Portuguese language course. For standardization, we binarized the outcome into pass or fail. POR contains 30 categorical and numerical features across 649 students. Similar to HSP, features in POR consist of general academic information (e.g., grades, attendance, etc.) and and individual difference measures. The MAT dataset undergoes the same transformation but is used to predict math grades.

Higher Education Student Performance Data (HSP): The HSP dataset is used to predict end-of-term grades. For our binary classification task, we transform the final grades as pass or fail. HSP contains 31 categorical and numerical features across 145 students in total. Features in this dataset focus on academics alongside a few individual difference measures (e.g., parental information).

3.2 Experiments

To answer RQ1, we applied four preprocessing-based unfairness mitigation methods: reweighting (Rw), FAIR-SMOTE (FSm), SMOTE (Sm), and Disparate Impact Remover (DRe). These methods were selected because they modify the data at different levels: reweighting adjusts instance weights without altering feature values, whereas SMOTE and FAIR-SMOTE generate synthetic samples to rebalance class and group distributions.

Reweighting (Rw) is a preprocessing technique designed to mitigate bias related to sensitive attributes. It assigns different weights to training instances based on the joint distribution of the sensitive attribute and the class label, reducing the influence of biased correlations during model training [22].

Table 2: AUC and fairness results of random forest models trained on the original and unfairness mitigated datasets.

Dataset	Mitigation	AUC	SP	DI	AO
HAR	–	.63	.05	1.20	.05
	Rw	.70	.06	1.11	.06
	FSm	.71	.07	1.19	.07
	Sm	.68	.05	1.21	.05
	DRe	.89	.04	0.91	.02
POR	–	.63	-.09	0.91	-.10
	Rw	.63	-.01	0.99	-.01
	FSm	.58	-.10	0.89	-.11
	Sm	.65	-.14	0.85	-.14
	DRe	.55	.07	0.92	.06
MAT	–	.58	.27	3.47	.27
	Rw	.61	.04	1.11	.04
	FSm	.64	.24	3.28	.24
	Sm	.63	.32	2.48	.32
	DRe	.44	.02	0.85	.04
HSP	–	.77	.03	1.07	-.15
	Rw	.60	-.04	0.91	-.07
	FSm	.53	-.03	0.93	-.12
	Sm	.51	-.23	0.62	-.36
	DRe	.79	-.05	0.67	-.02

FAIR-SMOTE (FSm) extends SMOTE by incorporating fairness constraints, generating synthetic samples that balance both class labels and sensitive attribute distributions [11].

SMOTE (Sm) addresses class imbalance by generating synthetic samples for the minority class through interpolation between existing instances and their nearest neighbors [12].

Disparate Impact Remover (DRe) applies a feature repair step that adjusts values so group-wise distributions align more closely with a fairness target (e.g., the "80% rule"), rather than changing instance weights or the label column [18].

We evaluated the effectiveness of these mitigation strategies using both predictive performance and fairness metrics. Predictive performance was measured using the area under the ROC curve (AUC). Fairness was assessed using statistical parity difference (SP), disparate impact (DI), and average odds difference (AO) [7, 41, 9]. For all experiments, we trained a random forest classifier with default hyperparameters to model student performance. The models were implemented using the *Scikit-learn* Python library, and the unfairness mitigation algorithms were implemented using the AI Fairness 360 toolkit and DebiasEd [27, 9, 34].

To answer RQ2, we analyze how each method transforms feature distributions. For each dataset, we compare the distributions of each feature before and after preprocessing using the Wasserstein distance (a metric that measures how different two distributions are by calculating how much work it would take to transform one into the other) [26].

4. RESULTS

The results of the unfairness mitigation on AUC and fairness measures is in Table 2. Considering that each dataset had differences in base rates between groups, we expected that the baseline model for each dataset could have bias due to differences in predicted rates. There is some bias in the baseline models denoted as the first row for each of the datasets in Table 2. Perfect fairness for SP and AO is 0, and perfect fairness for DI is 1. We report means across 5-fold cross-validation for each dataset.

For RQ1, we compared the fairness metrics of the baseline model with the fairness metrics of the models trained on the unfairness mitigated data. For each dataset, at least one model trained using unfairness mitigated data was fairer in terms of at least one metric. For example, Rw resulted in better DI by .09 given the HAR dataset. The MAT baseline showed the strongest bias (SP = .27, DI = 3.47, AO = .27). All four unfairness mitigation techniques were able to reduce bias with three of them also improving AUC in tandem. Thus, we conclude that the chosen preprocessing methods are capable of reducing gender bias in these models, albeit at differing levels.

Given some gender bias can be mitigated, we analyzed how the preprocessing differentiall impacts student data (RQ2). We found the average Wasserstein distance of the features before and after preprocessing across the four techniques and four datasets. The results are in Figure 1.

Our preliminary analysis finds slight trends in the data transformation of the mitigation methods. For example, generally, Rw and Sm transformed data more than the FSm and DRe methods. Also, while Rw had the highest Wasserstein distance across all features for HAR, the transformation did not relate to high levels of unfairness mitigation or AUC improvement. In fact, DRe resulted in better performance and fairness despite also having a lower Wasserstein distance. In contrast, DRe did not have better performance for MAT (the dataset with the highest gender bias) while still having the lowest Wasserstein distance. Thus, even though these four methods transform data at similar rates, our preliminary analysis does not find a relationship between the levels of transformation and the unfairness mitigated. The results further demonstrate this with three unique unfairness mitigation methods resulting in the least gender bias and these methods being unrelated to the level of data transformation.

5. DISCUSSION AND FUTURE WORK

The experiments revealed that preprocessing unfairness mitigation strategies are effective in reducing gender bias in grade prediction (RQ1), and examined how different types of preprocessing distort student data (RQ2). The results indicate that the preprocessing methods do not equally mitigate gender bias in grade prediction, and that inequality is seemingly not related to the amount that a dataset is transformed.

There are cases where preprocessing unfairness mitigation strategies can reduce gender bias in grade prediction within models trained on each of the datasets. However, the preprocessing methods are not equally effective for each dataset. As expected from previous research, different unfairness mitigation methods are more effective at improving certain dimensions of fairness [41]. At the same time, these statistical fairness definitions encode specific normative assumptions and improving them does not automatically imply equitable

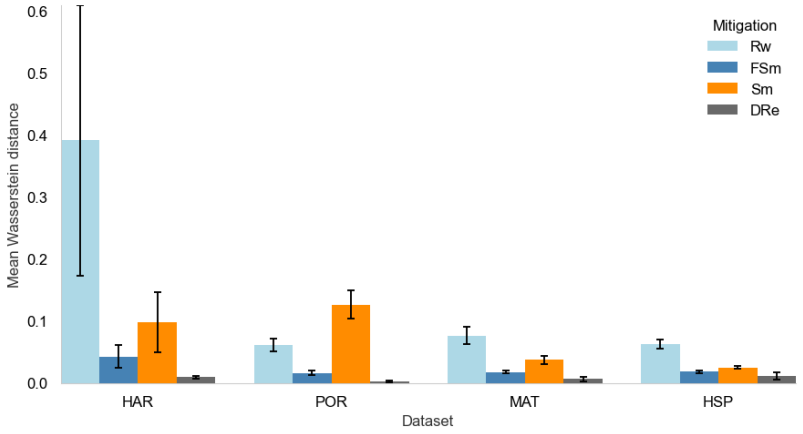

Figure 1: The average data divergence of the four unfairness mitigation methods on each of the datasets. On average, Rw distorts the data the most, followed by Sm, FSm, and DRe.

outcomes. However, notably, for the HAR and HSP datasets the model trained on a preprocessed version of the data using DRe resulted in a model that was fairer (in at least one dimension) *and* had better performance than the baseline. We also emphasize that mitigation is not uniformly beneficial: there are settings where fairness improves while AUC falls, where AUC improves while fairness worsens, or where one fairness metric improves while another degrades.

Preprocessing unfairness mitigation strategies having differential impacts on the data emphasizes the need for careful selection and adaptation of preprocessing unfairness mitigation methods in education. While DRe achieved fairness while minimally transforming the dataset, Rw achieved (sometimes better) fairness guarantees through distorting more data (in terms of the POR dataset). Furthermore, we found no relationship between the performance of a model, the unfairness of a model, and the amount in which the data was transformed. These findings are important for education researchers as they suggest that the most effective unfairness mitigation method is not necessarily the one that leads to the most transformation in the dataset. This flexibility in method is valuable in education as certain features being left untransformed could lead to greater explanatory power.

For practitioners, the correct mitigation to choose could be based on what must remain stable for the decision context: if preserving the literal feature values matters for communication and review, Rw may be preferable; if the priority is repairing dependence between protected attributes and outcomes in the input space, feature repair methods may be appropriate; if the issue is class imbalance, oversampling approaches may be relevant.

Therefore, future work can find mitigation strategies that improve fairness without sacrificing the transparency and interpretability of education models. Preprocessing techniques having seemingly no tradeoff between level of data distortion and unfairness mitigated offers opportunities for current preprocessing techniques to be improved and adapted for educational data. While DRe offers a possibility in this regard (through transforming only a few features), more research needs to be done to tailor this and other methods to education data. Moreover, Rw or Sm could be detrimental to the interpretability of models since they have greater data transformation. Furthermore, given that previous research has found that unfairness mitigation can transform certain features that could lead to procedural fairness harms [33], future work should move beyond our average estimates of Wasserstein distance. The next step would be to examine the specific features that are transformed by each preprocessing method. This could further provide insight into researchers as some methods could transform features that are important for model interpretability.

The study is limited by the sensitive attribute we chose to analyze, the unfairness mitigation techniques used, and the set of datasets. Since we focus on gender difference in grade prediction in a select set of tabular, categorical datasets, our results might not be generalizable to other types of data commonly used in educational data mining (e.g., knowledge tracing data [42]). Additionally, we only include a single (binary) sensitive attribute, which does not address intersectional fairness. Furthermore, we used only a few of an ever-increasing number of possible preprocessing unfairness mitigation techniques [19, 38]. Thus, our research could be further validated by testing the data distortion of other unfairness mitigation techniques.

The variability found in the relationship between dataset divergence, performance, and unfairness mitigation calls for multiple directions for future work. Our findings indicate that certain techniques could be promising in navigating this relationship, such as DRe, but future research needs to further test these hypotheses. Furthermore, future work can support the development of more education-specific preprocessing techniques with a focus on interpretability. Future extensions will include per-feature attribution of change (beyond dataset-level averages) paired with domain-informed features that must remain interpretable for instructors or advisors. Longer-term work could incorporate stakeholder-centered evaluation beyond offline metrics, and develop constraints common in education.

ABSTRACT

MetaPal is an intelligent system for cross-cultural empathetic oral dialogue education for international students, applying real-time multimodal affective computing to language education. Unlike traditional "command response" systems, MetaPal takes emotional empathy as the system core across all layers: perception, understanding, decision, and expression. The system fuses visual, audio, and text modalities, driving digital human interaction through an emotion-centered architecture that achieves a paradigm shift from "command response" to "emotional empathy." Through asynchronous processing, model lightweighting, and streaming transmission, the system achieves smooth real-time interaction. Small-scale user trials show positive feedback in oral confidence, cultural awareness, and emotional expression appropriateness. This demo presents the complete technical architecture, interaction process, and preliminary evaluation.

Keywords

Paradigm Shift, Affective Computing, Multimodal Fusion, Digital Human, Cross-Cultural Education

1. INTRODUCTION

1.1 Problem Background

Globalized education has intensified cross-cultural adaptation challenges for international students. Research shows that international students face significant challenges in learning and adjustment during their study abroad experiences [19]. Language learning presents specific challenges:

- **Emotional misunderstanding**: Reserved East Asian expressions are misinterpreted as indifference in Western contexts
- **Non-verbal cues**: Cultural differences in eye contact and facial expression create barriers
- **Vocal emotion**: Native tone transfer makes second language expressions seem emotionally flat

Traditional language tools focus on vocabulary and grammar, ignoring emotional and cultural dimensions. Existing affective computing research remains laboratory-based without systematic integration. Critically, current systems follow the "command response" paradigm, processing speech without perceiving emotional states—emotion is merely optional.

1.2 Related Work

As surveyed in [16], affective computing has established solid foundations for emotion-aware systems. **Application of Affective Computing in Education**: D'Mello et al. [4] analyzed emotional states during learning, showing emotion-cognition synergy is crucial. However, most studies use single modality without real-time multimodal fusion [3, 2]. Picard's foundational work [13] established affective computing as a field, while Pantic and Rothkrantz [11] pioneered affect-sensitive multimodal interaction.

Multimodal Learning Analytics: Existing classroom multimodal analysis frameworks have high latency, limiting real-time interaction support [12, 1]. Blikstein and Worsley [1] demonstrate computational approaches for measuring complex learning tasks.

Cross-Cultural Communication Theory: Hofstede's cultural dimension theory [8] provides a framework for quantifying cultural differences, but few studies have computationalized it for educational systems. Gao et al. [7] examine how cultural epistemologies influence emotional experience and regulation.

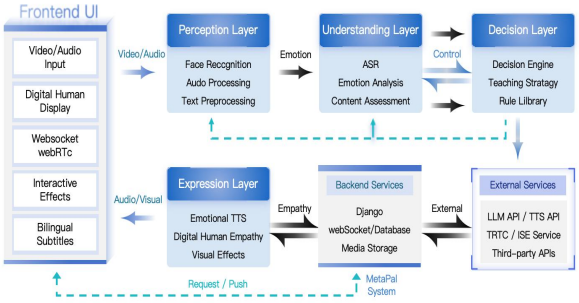

Figure 1: MetaPal architecture: Four-layer framework integrating perception, understanding, decision, and expression layers.

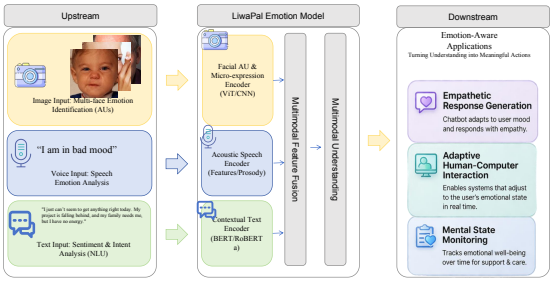

Figure 2: Perception layer: Real-time video capture with picture-in-picture slicing for emotion recognition.

1.3 Research Gap and Contributions

Research Gap: Existing systems lack real-time multimodal fusion, cross-cultural adaptation, and complete engineering implementation. Fundamentally, they follow "command response" logic with emotion as an add-on, while MetaPal takes "emotional empathy" as the operating system core across all layers.

Contributions:

1. **Theoretical**: Propose a new interaction paradigm with emotion as the underlying core—from "command response" to "emotional empathy."
2. **Technical**: Implement emotion-permeating architecture across perception, understanding, decision, and expression layers, with open-source reference.
3. **Practical**: Validate feasibility in real educational scenarios with user feedback and deployment solutions.

Positioning within EDM: While MetaPal draws on HCI and affective computing, its core contribution is **educational data mining**: real-time multimodal affective data as **educational data** to model cross-cultural emotional states in oral dialogue. Unlike prior EDM work on clickstreams or quizzes, MetaPal treats **emotion as a first-class educational data stream** addressing EDM 2026's "Crossing Boundaries" theme.

2. SYSTEM ARCHITECTURE

2.1 Overall Design: Empathetic Architecture

MetaPal implements a four-layer emotion-permeating architecture: perception, understanding, decision, and expression. The perception layer captures multimodal user data for emotion detection. The understanding layer integrates visual, audio, and text features through ViT-based emotion recognition [5], OpenSMILE audio analysis [6], and BERT semantic processing, all centered on emotional comprehension. The decision layer dynamically selects interaction strategies based on emotional states, while the expression layer generates emotionally appropriate responses through digital human feedback (Figure 1).

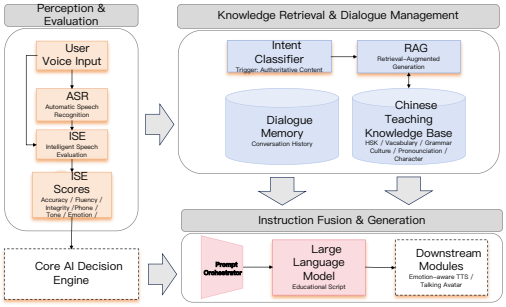

Figure 3: Understanding layer: Three parallel processing paths for multimodal emotional feature extraction and fusion.

2.2 Perception Layer: Emotion Capture

The perception layer captures user video in real-time through camera input, performs picture-in-picture slicing, and transmits the video stream to the backend affective computing module (Figure 2). Following large-scale video-based FER benchmarks [17], our system captures micro-expressions in real-time. Users' expressions, eye contact, and expressions are incorporated into the core processing flow as the starting point of interaction.

2.3 Understanding Layer: Emotion-Semantic Integration

The understanding layer achieves multimodal emotional feature extraction and fusion through three parallel paths: ViT-based visual emotion recognition, OpenSMILE audio emotion analysis, and BERT text semantic analysis (Figure 3). To handle real-world noise, we draw on dual-stage purification methods [14]. Emotion is integrated with semantic parsing—for example, when a user says "I'm fine" with a tense expression, the system interprets it as "tense fine" rather than "calm fine." This approach builds on multimodal affect detection research [3, 10] and affective body expression recognition [9].

2.4 Decision Layer: Emotion-Based Strategy Selection

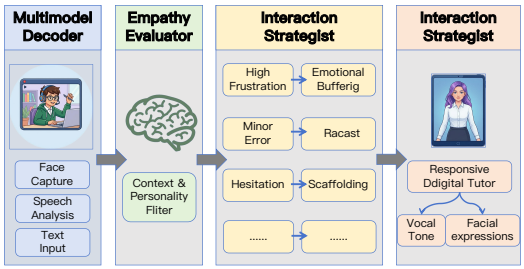

Figure 4: Decision layer: Dynamic strategy selection based on emotional states and learning context.

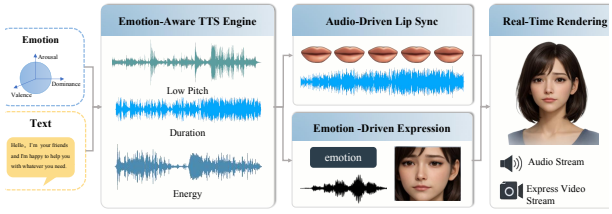

Figure 5: Expression layer: Emotion-driven generation of TTS audio, digital human animations, and visual effects.

The decision engine uses a finite state machine and rule library to dynamically select teaching strategies based on emotional states, cultural background, and learning progress (Figure 4). Emotion forecasting techniques [15] inspire our strategy selection engine. When users are tense, the system slows speech and encourages; when confused, it simplifies and provides scaffolding; when joyful, it increases difficulty and initiates challenges.

Cross-Cultural Parameterization: Hofstede's dimensions [8] are mapped to decision engine weights: power distance, individualism, uncertainty avoidance, and high/low-context communication preferences.

2.5 Expression Layer: Emotion-Driven Output

The expression layer generates TTS audio, digital human animations, and visual effects based on decision results (Figure 5). Audio tone, speed, and rhythm, along with digital human expressions, postures, and interaction methods, are all driven by emotional states to ensure responses are both semantically correct and emotionally appropriate.

3. EVALUATION AND PRELIMINARY FEEDBACK

3.1 Deployment

Figure 6 shows MetaPal deployment in a laboratory environment. Users participate in video calls with the digital human, while the system captures facial expressions in real-time via picture-in-picture for empathetic response.

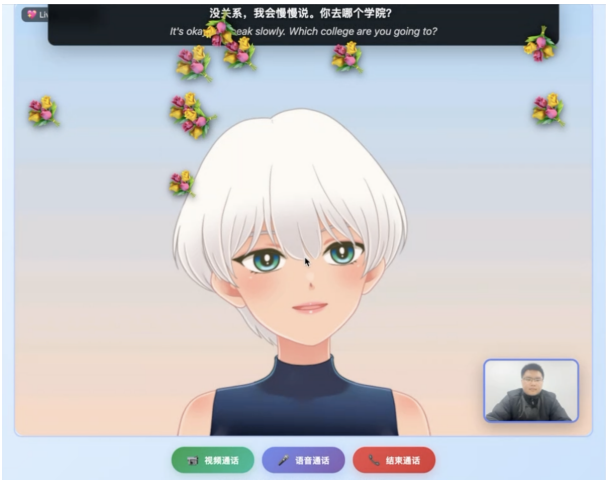

Figure 6: MetaPal deployment: Video calls with real-time emotion capture via picture-in-picture.

3.2 Trial Status

MetaPal is in laboratory prototype verification stage, validated through internal testing and small-scale user trials. The system operated stably with smooth real-time interaction, accurate multimodal emotion recognition, and good audio-visual synchronization.

Participants: International students (N=limited, B1-B2 English) from multiple Asian cultural backgrounds. This diverse sample enables examination of cultural differences in emotional expression [18, 7].

Cross-Cultural Validation: To evaluate the system's cross-cultural adaptation capability, we compared user responses across participants from different cultural backgrounds (Chinese, Korean, Vietnamese). Hofstede's cultural dimension scores [8] for each country were used as reference baselines. Preliminary analysis showed that the system's emotion recognition thresholds appropriately shifted: for example, users from high-context cultures received higher sensitivity weights on facial expression and prosody features, while users from low-context cultures relied more on semantic content analysis. This alignment between system parameters and cultural dimension predictions suggests the feasibility of computationalizing cross-cultural communication theory.

Ethics and Privacy: All trials were conducted with informed consent from participants. As this was a minimal-risk prototyping study, facial expression data were processed in real time and not stored beyond the session; only anonymized behavioral logs were retained for analysis.

Process: Participants completed several weeks of cross-cultural dialogue training with real-time feedback. User experience was collected through questionnaires and interviews, following established methods for evaluating affective educational systems [2].

3.3 Preliminary Results

Small-scale trials showed positive feedback in oral confidence, cultural awareness, and emotional expression. In one case, a user said "Thank you for your help" with a flat expression. The system detected the mismatch and the digital human smiled while explaining gratitude customs in Western culture. User feedback:

> "The system taught me that in Western culture, 'Thank you' needs a smile to be sincere. I wasn't aware of this before."

This demonstrates the paradigm shift—the system "felt" the user's expression and responded emotionally, not just processing the words.

4. DISCUSSION AND CONTRIBUTIONS

4.1 Theoretical Contributions

1. **Paradigm Shift**: MetaPal reconstructs human-computer interaction with emotion as the operating system core across all layers. Command response becomes a subfunction, while emotional empathy drives the interaction, shifting from task-completion to relationship-building.
2. **Emotion-Culture Interaction Model**: Integrates Hofstede's cultural dimension theory [8] into real-time emotion recognition, enabling culturally adaptive expression interpretation.
3. **Multimodal Emotion Fusion**: Verified synergistic effects of visual, audio, and text modalities in language learning.

4.2 Technical Contributions

1. **Emotion-Permeating Architecture**: Implemented four-layer architecture with emotion integrated throughout, providing technical reference for real-time emotional feedback.
2. **Open-source Implementation**: System architecture and core code will be open-sourced on Gitee after acceptance.
3. **Emotional Decision Engine**: Real-time emotion recognition via video calls with dynamic cross-cultural feedback strategies.

4.3 On System Integration as Contribution

We acknowledge that MetaPal builds on established components (ViT, BERT, OpenSMILE, FSM). However, for a **Demo Track** paper, the contribution lies not in proposing new base models, but in demonstrating **how existing technologies can be systematically integrated to solve a real, under-addressed educational problem**. In MetaPal's case, this integration requires: (1) real-time fusion of three modalities under latency constraints, (2) cross-cultural adaptation of emotion recognition thresholds, and (3) driving a digital human's empathetic response. We argue that **system-level innovation**—making working, deployable systems that address genuine educational gaps—is a distinct and valuable form of contribution, complementary to model-level advances, and precisely what EDM's Demo Track is designed to showcase.

4.4 Practical Contributions

1. **Prototype Validation**: Demonstrated technical feasibility in laboratory environment, with real-time multimodal processing under 500ms latency.
2. **Training Solution**: Provided cross-cultural empathetic oral training for international students, addressing emotional expression gaps often overlooked by traditional language tools.
3. **Cross-disciplinary Model**: Demonstrated collaboration across computer science, education, linguistics, and psychology, offering a reusable blueprint for emotion-aware educational systems.
4. **Real-time Fusion Pipeline**: Achieved synchronized processing of video, audio, and text streams with $<$500ms end-to-end latency, enabling natural turn-taking in cross-cultural dialogue.

5. DEMO CONTENT

A demonstration video is submitted as supplementary material, showing live interaction between a user and the MetaPal digital human. The complete system will be open-sourced after acceptance.

6. CONCLUSIONS

MetaPal demonstrates the feasibility of emotion-centered human-computer interaction, providing cross-cultural empathetic oral training for international students. The system bridges computer science and education, with core contributions including:

1. **Paradigm Shift**: Emotion as the operating system core across all layers, redefining interaction from command completion to emotional understanding.
2. **System Completeness**: Complete technical architecture: real-time multimodal perception, emotion-semantic understanding, strategy decision, and empathetic expression generation with full pipeline integration.
3. **Scalability**: Foundation for future large-scale applications with plug-and-play modules for emotion recognition and strategy selection.
4. **Cross-Cultural Adaptability**: Demonstrated real-time parameterization of Hofstede's cultural dimensions for personalized emotion recognition and dialogue strategy adjustment.

Future work will conduct larger-scale experiments to verify educational effectiveness, extend the framework to more cultural contexts (e.g., Latin American, Middle Eastern), and integrate LLM-based open-domain dialogue capabilities.

ABSTRACT

Modern educational settings routinely generate massive amounts of learning event sequences, which often exhibit complicated temporal and sequential dependencies among events. Traditional sequence dependency analysis methods, such as sequential pattern mining, requires researchers to manually configure pattern parameters, such like minimum support, positional gap, and time interval, which introduces subjectivity into the analysis process. Meanwhile, deep learning models combined with temporal point processes, particularly Hawkes processes with attention mechanisms, have shown promise in capturing sequential dependencies and predicting future events, yet existing models remain limited in the interpretability of the dependency features they identify. To address these limitations, this study proposed a method based on self-attentive Hawkes processes to identify the sequential dependencies in learning event sequences without requiring manual configuration of pattern parameters. We applied the proposed method to two learning event datasets and compared the extracted patterns with those mined by two baseline algorithms. The results revealed a relatively small degree of pattern overlap between the proposed method and baselines. For overlapping patterns, the proposed method identified temporal characteristics differed significantly from that of baselines, which were manually preset.

Keywords

Learning event dependency, sequential pattern mining, temporal pattern mining

1. INTRODUCTION

Learning process data are typically represented as sequences of learning events that partially reflect learners' cognitive processes and behavioral patterns. The temporal sequential relationships among learning events, referred to as sequential dependencies, hold significant pedagogical value [1]. They can support a wide range of educational applications, such as learning performance prediction and learning environment design. For example, sequential dependencies in MOOC learning events can serve as features to predict students' dropout risk [2]; that in video viewing behaviors can help reveal the engagement with instructional videos [3]; and that in the resource usage behaviors among a certain group of learners can be transformed into learning paths recommended to other learners in the same group [4].

A range of methods has been used to analyze sequence dependencies in learning events, include sequential pattern mining (SPM), lag sequential analysis, process mining, and ordered network analysis [5]. However, except for SPM, these methods are generally limited to characterizing pairwise dependencies between events and have difficulty capturing the overall sequential dependencies among multiple learning events. SPM can mine sequence patterns of various lengths [6] and has been widely used in descriptive, relational, and predictive studies [7, 8, 9], such as mining learning behaviors, generating features for prediction and classification models, and filtering learning resources to build recommendation systems. However, it relies on researchers' manual setup of pattern parameters, such as the minimum support (the minimum sequences containing a pattern) as well as positional gaps and time intervals among adjacent pattern events. Because these preset parameters inevitably involve subjective judgment, the manual setup creates a gray area in the analytical process that may introduce bias into the results [10], thereby influencing researchers' understanding of learning patterns.

Recent advances in deep learning have combined deep neural networks with temporal point process models to characterize sequential dependencies while taking into account factors such as event position and time interval, thereby enabling future event prediction [11]. Among these models, Hawkes-process-based approaches are particularly suitable because they capture how prior events influence subsequent events over time. Accordingly, Hawkes processes have been widely applied to event prediction tasks, such as predicting procrastination in online learning [12]. More recently, attention-based extensions such as the self-attentive Hawkes process (SAHP) [13] and the Transformer Hawkes Process [14] have further improved the modeling of event sequences and outperformed recurrent neural network-based Hawkes process models in future event prediction. However, these models are primarily designed for event prediction and extrinsic target classification, which limits their usefulness for extracting interpretable sequential dependency features.

To address these limitations, this study proposes a novel method that combines the self-attentive Hawkes process with the task of mining learning event sequential dependencies. The proposed metho aims to reduce reliance on manually preset pattern parameters while extract interpretable patterns of learning events with relatively strong sequential dependency. To evaluate its effectiveness in relation to traditional sequence dependency analysis, this study compares the patterns and time intervals identified by the proposed method with those obtained from baseline SPM algorithms. Specifically, this study examines the following research questions:

- RQ1: To what extent do the pattern sets mined by the proposed method overlap with those mined by baseline SPM algorithms?
- RQ2: For overlapping patterns, how do the time intervals automatically identified by the proposed method compare with those preset in baseline SPM algorithms?

2. METHODOLOGY

We refer to the proposed method as the leSPM-SAHP algorithm. It builds on the SAHP architecture [13] because SAHP showed high performance in modeling event dependencies and event prediction while incorporating temporal order and time intervals, making it suitable for learning-event sequence analysis. Specifically, in self-supervised learning where the task is the next event prediction, the model uses the attention output O, derived from the query (Q), key (K), and value (V) matrices, to quantify the influence of historical events on subsequent events.

$$O = AV \quad A = \mathrm{Softmax}\left(\frac{QK^T}{\sqrt{M_K}}\right)$$

$$Q = XW^Q, \quad K = XW^K, \quad V = XW^V$$

The value a_{ij} in the i-th row and j-th column of the attention weight matrix A represents the strength of sequential dependencies of event (k_i, t_i) on historical event (k_j, t_j) [14]. k_i is the event type of the i-th event, while t_i is the time elapsed since the first event. To prevent overly distant events from contributing noise, we introduced a history-length regularization parameter ℓ, which restricts attention to a bounded temporal context by forcing attention weights beyond ℓ positions to approach zero. Correspondingly, if $i - j > \ell$, a_{ij} approaches 0.

Based on the resulting attention weights, leSPM-SAHP first identifies candidate pairwise sequential dependencies between events. For each event pair, a Wilcoxon signed-rank test is used to determine whether its attention weights are significantly greater than the baseline threshold ($\frac{1}{\ell+1}$), so that only statistically significantly dependencies are retained.

Because pairwise dependencies correspond only to patterns of two events, we then extend them into longer patterns through a layer-linking pattern expansion procedure. This procedure is motivated by the ability of higher-order attention layers to encode dependencies involving multiple events. By sequentially linking sequence patterns across adjacent layers, short dependencies are progressively expanded into longer event sequence patterns.

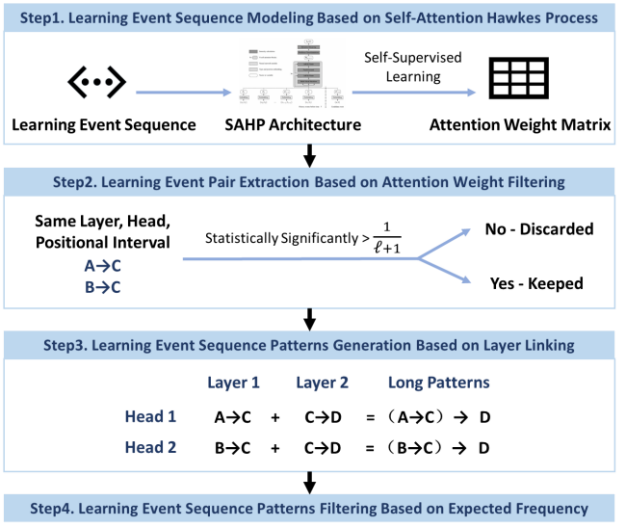

Figure 1. The workflow of leSPM-SAHP

Finally, to reduce spurious or practically uninformative outputs, all extracted patterns are filtered using an expected-frequency criterion, which were based on the product of the simple frequencies of pattern events. Patterns with occurrence frequencies lower than their expected frequency in the event sequences are removed, and the remaining patterns constitute the final pattern set. This design allows leSPM-SAHP to reduce reliance on manually preset pattern parameters in traditional SPM while preserving interpretable pattern and time-interval information for comparison with baseline SPM algorithms.

3. EXPERIMENT

3.1 Datasets

We evaluated leSPM-SAHP on two contrasting learning-event datasets, a large-scale *XuetangX MOOC*[1] dataset and an event-rich middle-school science game dataset, *Wake: Tales from the Aqualab*[2], to examine whether the method performs consistently across different learning contexts. Table 1 displays basic statistics of the two datasets. To reduce excessively long inactive gaps, sequences in both datasets were split whenever the interval between adjacent events exceeded 15 minutes.

Table 1. Basic Information of Datasets

Dataset	Student Type	Number of Students	Mean Sequence Length (*SD*)	Number of Event Type
MOOC	Multiple Types	6343	157.65 (*568.51*)	21
Aqualab	Middle School Students	590	817.01 (*1492.10*)	58

[1] http://moocdata.cn/data/user-activity

[2] https://opengamedata.fielddaylab.wisc.edu/gamedata.php?game=AQUALAB

3.2 Baselines

We compared leSPM-SAHP with two recent temporal pattern mining baselines, both of which support time-interval sequential patterns extraction:

- **OER-Miner (2025):** This method employed episode connection strategies and position index support calculation to efficiently mines sequential patterns with time interval constraints [15].
- **TIRPClo (2023):** It achieves complete temporal interval pattern mining through entity projection based on endpoint sequence transformation and memory indexing [16].

3.3 Analysis

For leSPM-SAHP, model hyperparameters were selected using 5-fold cross-validation, and attention-weight filtering used a significance level of 0.05. For the baselines, pattern sets were extracted under multiple combinations of minimum support and maximum time-interval settings to provide a systematic comparison across parameter conditions (Table 2). A pattern was returned by the baseline only when the proportion of sequences with at least one valid pattern instance was no less than the minimum support, and a pattern instance was valid when the time interval between adjacent events was not greater than the maximum time interval.

Table 2. Settings of Pattern Parameters. 25th TI denotes the time interval at the 25th percentile rank among all event time intervals (the time interval between the first event of a sequence and all other events in the sequence)

Dataset	Parameter	Level
MOOC	Minimum Support	0.15, 0.20, 0.25, 0.30
	Maximum Time Interval	25th TI, 50th TI, 75th TI
Aqualab	Minimum Support	0.55, 0.60, 0.65, 0.70
	Maximum Time Interval	25th TI, 50th TI, 75th TI

Under each combination of pattern parameters, we compared the filtered pattern set P produced by leSPM-SAHP with the baseline pattern set P_{base} (see Figure 2). Specifically, a denotes the count of patterns identified only by leSPM-SAHP, b denotes the count of patterns identified only by the baseline method, and c denotes the count of overlapping patterns. Before filtering, the corresponding counts were recorded as a', b', c'. For the overlapping patterns (c), we further compared the differences in maximum time interval identified by leSPM-SAHP with those preset in the baseline SPM algorithms.

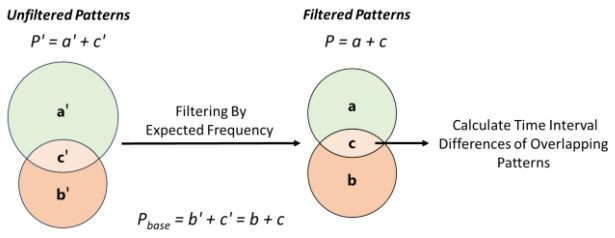

Figure 2. Metrics for comparing leSPM-SAHP with baselines. P' was the unfiltered pattern set extracted by leSPM-SAHP, while P was the filtered pattern set. P_{base} was the pattern set extracted by the baselines

We focused on three metrics of pattern overlapping: $\frac{c}{a+c}$, $\frac{b}{b+c}$, and $\frac{b\prime}{b\prime+c\prime}$. If $\frac{c}{a+c}$ is small and the interval difference is large, it means that the sequence patterns extracted by leSPM-SAHP cannot be covered by existing algorithms. If $\frac{b}{b+c}$ is large and $\frac{b\prime}{b\prime+c\prime}$ is small, it indicates that many patterns extracted by baselines existed in the unfiltered pattern set by leSPM-SAHP but not in the filtered pattern set, which means baselines may extract many patterns without relatively strong event dependencies as their frequencies lower than the expected frequency.

4. RESULTS & DISCUSSION

In the MOOC dataset, the number of patterns mined by OER-Miner ranged from 23 to 2385, that by TIRPClo ranged from 16 to 794, while that by leSPM-SAHP was 630. In the Aqualab dataset, the number of patterns mined by OER-Miner ranged from 765 to 7305, that by TIRPClo ranged from 603 to 6728, while that by leSPM-SAHP was 3653.

As shown in Figure 3, in both datasets, $\frac{c}{a+c}$ consistently remained at a low level, with mean values of 3.46% and 0.76% for MOOC and Aqualab datasets, respectively. This indicates that only a small proportion of the sequential patterns in the filtered set extracted by leSPM-SAHP overlapped with those extracted by the baseline algorithms. In other words, most patterns identified by leSPM-SAHP were not covered by the baseline under the tested parameter settings.

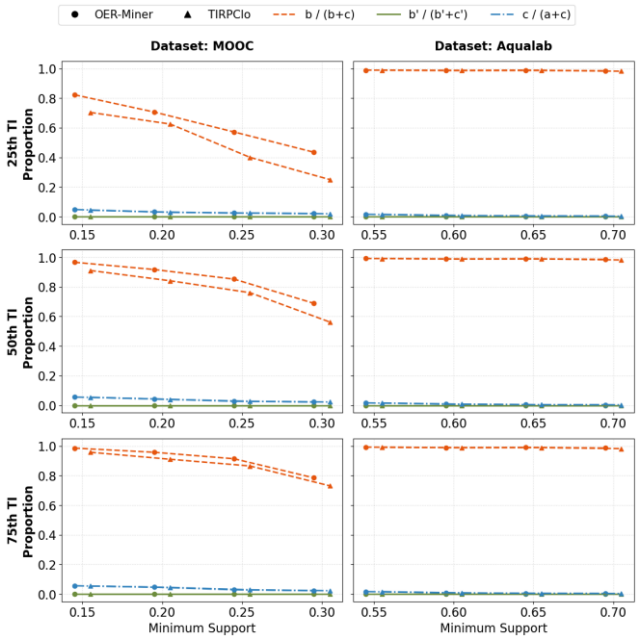

Figure 3. The three metrics under each parameter combination

More importantly, across all combinations in both datasets, $\frac{b\prime}{b\prime+c\prime}$ was 0. This indicates that the patterns extracted by the baseline algorithms were also present in the unfiltered output of leSPM-SAHP. However, in the Aqualab dataset, $\frac{b}{b+c}$ remained at a high level, fluctuating between 98.14% and 99.19%, and in the MOOC dataset, it was also large under many parameter combinations, although smaller in some conditions. Taken together, these results suggest that the divergence between leSPM-SAHP and the baseline methods arose primarily from the filtering stage rather than from a failure of leSPM-SAHP to initially identify the patterns extracted

by the baselines. In other words, many patterns extracted by the baseline algorithms existed in the unfiltered pattern set of leSPM-SAHP but were not retained after filtering. This suggests that frequency-based SPM algorithms may preserve many patterns that satisfy support-based criteria but are not retained under the dependency- and expected-frequency-based filtering procedure of leSPM-SAHP.

For overlapping patterns, we next examined whether the maximum time intervals identified by leSPM-SAHP differed significantly from those preset in the baseline SPM algorithms. For each fixed combination of dataset, maximum time interval, algorithm, and minimum support, we tested whether the time interval differences significantly differed from zero using the Wilcoxon signed-rank test. To control for error due to multiple comparisons, p-values were adjusted using the Benjamini-Yekutieli correction.

Figure 4 displays the heatmap of mean time interval differences across datasets, maximum time intervals, baseline algorithms, and minimal support. In the MOOC dataset, the time interval differences were uniformly positive across all conditions, and all 24 cells were statistically significant. This indicates that, for overlapping patterns, the maximum time intervals identified by leSPM-SAHP were consistently larger than those preset in the baseline methods.

In Aqualab, time interval differences were also consistently positive and significant under the 25th and 50th TI thresholds. By contrast, under the 75th TI threshold, all Aqualab cells turned negative, and five of the eight cells remained statistically significant after correction. Thus, while the MOOC results showed a stable pattern of larger time intervals under leSPM-SAHP, the Aqualab results suggest that the direction and magnitude of time interval differences depended on the maximum time interval condition. This set of findings addresses RQ2 by showing that, even for overlapping patterns, leSPM-SAHP and the baseline SPM algorithms often assigned different temporal spans to the same pattern.

Taken together, the results indicate that the overlap between leSPM-SAHP and the baseline SPM algorithms was limited in both datasets, and that the temporal characteristics of overlapping patterns often differed significantly. A plausible explanation is that existing SPM algorithms depend on manually preset pattern parameters, such as minimum support and maximum time interval, whereas leSPM-SAHP does not rely on such preset thresholds in the same way and instead derives dependency information from the data through the SAHP model structure and filtering procedure. From this perspective, leSPM-SAHP may capture sequential patterns and time intervals among learning events that are not easily recovered when pattern parameters must be specified in advance. More broadly, these findings suggest that sequence dependency analysis in educational data mining may benefit from approaches that infer temporal and frequency constraints adaptively from data rather than relying on researcher-defined parameter settings.

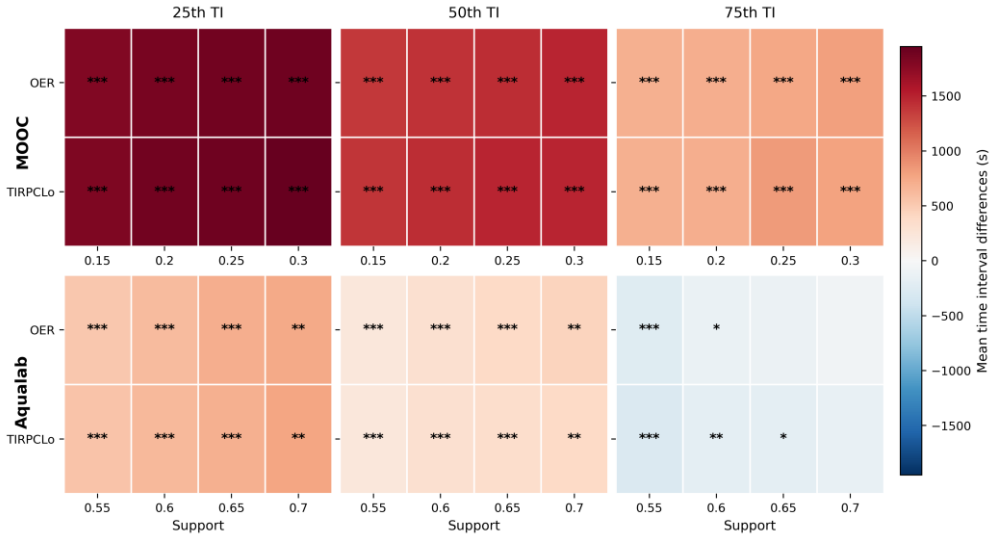

Figure 4. Comparison of time interval differences for overlapping patterns under each condition. Asterisks denote Benjamini-Yekutieli-adjusted significance against 0 (* $p < .05$, ** $p < .01$, *** $p < .001$)

5. LIMITATIONS AND FUTURE WORK

At the same time, these findings should be interpreted with caution. Low overlap does not by itself prove that leSPM-SAHP identifies more meaningful patterns than the baseline methods; rather, it shows that the proposed method yields substantially different outputs under the present comparison framework. Similarly, the fact that many baseline patterns were filtered out by leSPM-SAHP suggests that those patterns were not retained under dependency-based screening, but it does not by itself establish that they are substantively unimportant. Additional validation is therefore needed to examine whether the patterns preferentially retained by leSPM-SAHP are indeed more informative, interpretable, or pedagogically useful in real educational settings.

For overlapping patterns, this study only compared their time interval differences. Future research should further examine positional interval differences to provide a more complete comparison of pattern features across methods. Additionally, this study utilized only two datasets and two baseline algorithms. Subsequent research should extend the comparisons to data from more diverse learning contexts and a broader range of algorithms to investigate whether the degree of pattern overlap depends on dataset characteristics or algorithmic assumptions.

Multi-Feature Knowledge Tracing with Time-Series Interpretability for Mathematics Teacher Micro-Credentials

Hai Li
University of Florida
li.ha@ufl.edu

Chenglu Li
University of Utah
chenglu.li@utah.edu

ABSTRACT

Teacher professional development (PD) is critical for instructional improvement, and online micro-credentials provide flexible, work-embedded learning opportunities. Knowledge tracing (KT) can support personalization by modeling knowledge state evolution, but systematic application to adult professional learners remains limited, particularly when interaction logs are multi-dimensional and models must balance predictive performance with interpretability under small-sample constraints. Focusing on mathematics teacher micro-credentials, we propose a multi-feature deep KT framework with built-in temporal interpretability. We organize heterogeneous log-derived features into a progressive six-layer hierarchy and apply mutual information-based selection, which is well-suited for small-sample, feature-rich environments. Our residual-injection Time Interpretation Module (TIM) augments LSTM-based Deep Knowledge Tracing with lightweight temporal encoding and causal self-attention, providing intrinsic interpretability through temporal feature importance analysis. Evaluated on a dataset comprising 154 teachers and 22,988 interactions, results demonstrate that compact core-feature configurations achieve strong predictive performance, while indiscriminate feature addition degrades accuracy due to dimensionality effects. TIM improves both predictive performance and training stability while revealing interpretable temporal dynamics distinctive to adult professional learners. The framework offers systematic guidance for KT-based support in resource-constrained professional learning contexts.

Knowledge Tracing, Teacher Professional Development, Time-Series Interpretability, Multi-Feature Integration

1. INTRODUCTION

Teacher professional development (PD) is widely viewed as a high-leverage route to improving instruction and student outcomes [29, 6]. Contemporary PD increasingly emphasizes personalization, work-embedded learning, and competency-oriented certification through *micro-credentials* that enable modular, flexible asynchronous participation [7, 22]. A central goal is strengthening *Pedagogical Content Knowledge (PCK)* in authentic instructional contexts [3].

Knowledge Tracing (KT) offers data-driven modeling of knowledge state evolution and can underpin adaptive support systems [5, 25]. The field has progressed from Bayesian Knowledge Tracing (BKT) and Performance Factors Analysis (PFA) [24] to LSTM-based Deep Knowledge Tracing (DKT) [25] and attention-augmented architectures [30, 23, 21]. Recent advances have further enhanced KT through multi-time series feature integration [13] and option-level tracing for mathematics assessment [15]. LSTM-based models combined with attention mechanisms represent well-established approaches for capturing temporal dependencies in learner sequences [1]. However, systematic application to adult professional learners remains limited, particularly in asynchronous micro-credential settings where learning rhythms, communicative patterns, and constraints differ substantially from traditional educational environments [19].

Teachers, as adult learners, exhibit autonomy, experience-based reasoning, and problem-centered learning consistent with *andragogy* [9]. Their professional learning involves complex instructional judgments and deep PCK integration [20]. Using data from a mathematics teacher micro-credential program, we observe distinctive properties: highly concentrated sessions, notably high item difficulty (overall accuracy 33.37%), and substantial variation in skill mastery across 12 teaching dimensions. These characteristics suggest that systematic feature engineering and temporal modeling are particularly important in this context.

Methodologically, teacher PD platforms generate multi-dimensional logs encompassing behavioral, temporal, and performance signals, yet feature processing in existing KT work is often ad hoc [11]. Small-sample, feature-rich settings amplify overfitting risks and dimensionality issues. Additionally, many deep KT models lack intrinsic interpretability for temporal dynamics [1], limiting their utility in professional learning contexts where stakeholders need to understand prediction mechanisms.

We address two research questions that systematically tackle these challenges:

RQ1: How do different log-derived features, organized via a progressive hierarchy and selected through mutual information, affect KT predictive performance in a small-sample professional learning setting?

RQ2: How can a lightweight, residual-injected temporal module enhance LSTM-based DKT performance while providing interpretable temporal dynamics?

2. RELATED WORK

2.1 Knowledge Tracing and Temporal Modeling

KT has evolved from BKT's Hidden Markov Models [5] and PFA's logistic regression with engineered predictors [24] to DKT's recurrent sequence modeling [25]. LSTM-based architectures combined with attention mechanisms are well-established for capturing temporal dynamics in learner modeling [30, 23, 21, 1]. Models such as Dynamic Key-Value Memory Networks (DKVMN) have introduced structured memory mechanisms that provide specific levels of interpretability [21]. Temporal modeling and forgetting effects remain active areas of development [4].

Despite these advances, most KT evidence derives from student learning contexts. Teachers as adult learners follow andragogy principles including self-direction and experience integration, implying KT models must accommodate higher-order cognitive processes distinct from student content learning. Micro-credentials further amplify these differences through competency-oriented certification and asynchronous pacing [22].

2.2 Multi-Feature Integration and Interpretability

As learning platforms expand, KT research increasingly integrates process data such as response time, hints, and navigation paths to improve prediction [1, 17, 2]. Parallel developments in mathematics education have demonstrated the value of multimodal features for automated feedback [12] and collaborative filtering approaches for automatic scoring [16]. However, several methodological challenges persist: feature construction for heterogeneous logs remains largely unstructured, with limited systematic use of nonlinear dependency metrics such as mutual information [10]; temporal features are often incorporated via simple concatenation, which struggles to capture complex sequential effects [4]; and model interpretability typically relies on post-hoc tools such as SHAP or LIME [18, 27], making it difficult to isolate the role of specific temporal features [28].

3. METHOD

We model teacher learning as sequence $\mathcal{S} = \{(s_t, q_t, r_t)\}_{t=1}^{T}$, where s_t denotes skill ID ($K = 12$), q_t question ID ($Q = 127$), and $r_t \in \{0, 1\}$ binary response. The prediction goal is $p_t = P(r_t = 1 \mid \mathcal{S}_{<t}, \boldsymbol{f}_t)$.

3.1 Platform Context and Dataset Construction

The data originates from an asynchronous mathematics teacher micro-credential platform deployed in the southeastern United States (September 2024–February 2025). The platform supports practicing educators working toward competency-based certification through modular courses. Assessment items consist of complex pedagogical judgment tasks where teachers analyze authentic classroom scenarios and identify specific instructional strategies such as revoicing, fostering reasoning, and leveraging student errors. These higher-order tasks target PCK integration, which accounts for the dataset's notably low overall accuracy and substantial cross-skill variation.

We align four heterogeneous data sources at teacher and course levels: assessment response records, content learning progress, platform interaction logs, and course metadata. The learning environment follows a standard dashboard-content-assessment workflow where teachers access materials, attempt items, and receive feedback within an integrated web platform. All data were de-identified prior to analysis under institutional data agreements and ethics review protocols. Preprocessing follows three rigorous principles: features with $> 70\%$ missingness are dropped to limit imputation bias; response-time outliers (< 1s or > 3600s) are removed; and strict temporal ordering is enforced via cumulative `time_since_last_attempt` to prevent future leakage.

Dataset Summary: The final dataset comprises **22,988 valid interaction records from 154 teachers**, covering **127 items across 12 skills**, with overall accuracy 33.37% and average sequence length 149.3 ± 30.2 items per teacher. Temporal characteristics reflect concentrated adult learning behavior: **99.84% of consecutive responses occur within sessions** (< 6 minutes apart), while long intervals (> 1 week) account for only 0.14% of transitions.

3.2 Training Protocol and Statistical Rigor

Given the relatively small teacher cohort (**154 teachers**) paired with high interaction volume (**22,988 records**), teacher-level generalization is the primary evaluation concern. We apply teacher-level stratified splits with complete isolation: **Training (107 teachers, 16,065 records, 69.9%), Validation (23 teachers, 3,538 records, 15.4%), Test (24 teachers, 3,385 records, 14.7%)**. This ensures evaluation reflects true generalization to unseen teachers.

Optimization uses Adam ($\beta_1 = 0.9$, $\beta_2 = 0.999$, lr=0.001) with class weights (pos_weight=1.99) to address class imbalance, label smoothing ($\epsilon = 0.02$), gradient clipping (max_norm=0.8), and early stopping (patience=5). To ensure robust statistical reporting, **each configuration runs with 5 independent random seeds (42–46)**, with results reported as empirical mean $\pm$ standard deviation. We use variance reduction across seeds as the primary stability indicator, which provides reliable evidence of model improvements under deep learning initialization variability.

3.3 Progressive Feature Engineering (RQ1)

We organize features into a six-layer hierarchy from core to contextual, enabling controlled evaluation of each feature group's contribution under small-sample constraints (Table 1). This design systematically addresses the practical question of which feature subsets offer optimal performance-cost tradeoffs for deployment.

Mutual information $I(f; r) = \sum_{f,r} p(f, r) \log \frac{p(f,r)}{p(f)p(r)}$ is com-

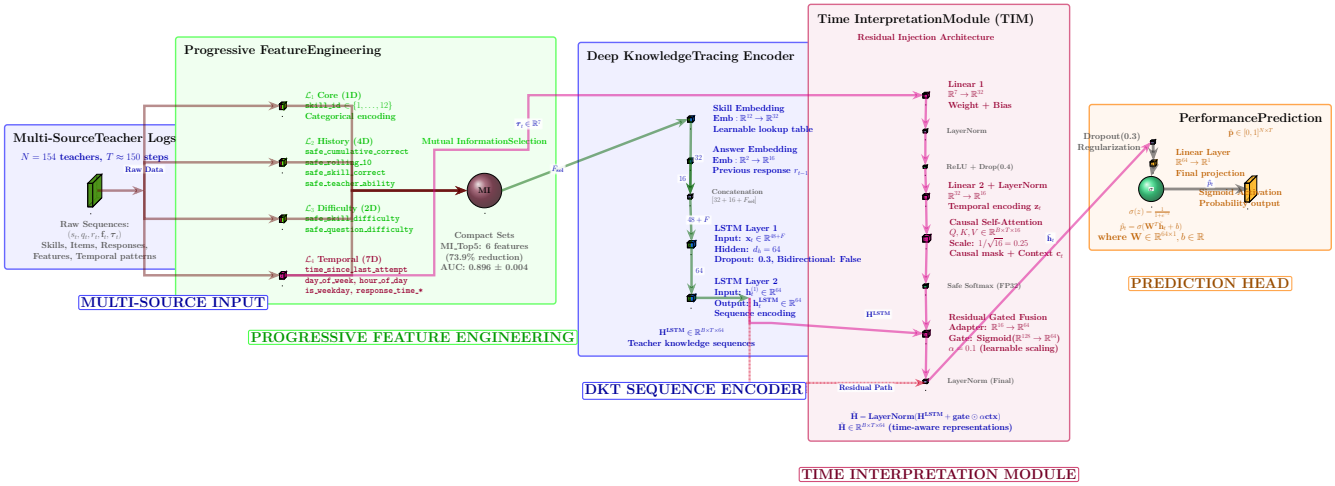

Figure 1: Overall architecture of the multi-feature DKT framework with residual-injection Time Interpretation Module (TIM).

Table 1: Progressive Feature Hierarchy System

Layer	Category	Variables & Description	No.
$\mathcal{L}_1$ *Core (L1_Baseline)*			
	Skill	`skill_id`: 12 categories, 32-dim embeddings	1
$\mathcal{L}_2$ *Performance History*			
	History	`cumulative_accuracy`, `rolling_accuracy_10`, `skill_accuracy`, `teacher_ability`	4
$\mathcal{L}_3$ *Difficulty Parameters*			
	Difficulty	`item_difficulty`, `skill_difficulty`	2
$\mathcal{L}_4$ *Temporal Features*			
	Temporal	`time_since_last_attempt`, `hour_of_day`, `day_of_week`, `is_weekday`, `response_time_seconds`, `response_time_log`, `response_time_zscore`	7
$\mathcal{L}_5$ *Behavioral Features*			
	Behavioral	`total_learning_time`, `total_visits`, `avg_time_per_visit`, `questions_per_hour`, `total_attempts_by_user`	5
MI Selection (MI_TopK)			
	Selection	Top-K by mutual information (K=5,10,15)	6,11,16

Full configuration: L1(1)+L2(4)+L3(2)+L4(7)+L5(5)=19 total features.

puted via k-nearest-neighbor estimation [10], ranking 18 non-core features to construct MI_Top5/10/15 configurations. This nonlinear dependency metric is particularly effective for capturing complex feature-response relationships in small-sample, feature-rich settings where linear correlation may underestimate feature relevance.

3.4 LSTM-based DKT with Time Interpretation Module (RQ2)

The base DKT concatenates skill embedding $\boldsymbol{e}_s(s_t) \in \mathbb{R}^{32}$, answer embedding $\boldsymbol{e}_a(r_{t-1}) \in \mathbb{R}^{16}$, and auxiliary features $\boldsymbol{f}_t$ into input $\boldsymbol{x}_t$. A 2-layer LSTM (hidden size 64, dropout 0.3) encodes $\boldsymbol{h}_t = \text{LSTM}(\boldsymbol{x}_t, \boldsymbol{h}_{t-1})$, with prediction $p_t = \sigma(\boldsymbol{w}^\top \boldsymbol{h}_t + b)$.

Table 2: Model Performance Analysis (mean ± std, 5 runs, sorted by AUC)

Configuration	Feat.	AUC	F1	Acc.
BKT (Baseline)	1	0.445 ± 0.000	0.122 ± 0.000	66.5%
PFA (Full)	19	0.769 ± 0.000	0.508 ± 0.000	73.4%
DKT (Full)	19	0.777 ± 0.008	0.610 ± 0.004	67.5%
DKT (MI_Top15)	16	0.894 ± 0.011	0.749 ± 0.016	83.0%
DKT (MI_Top5)	6	0.894 ± 0.006	0.750 ± 0.012	82.9%
DKT (L1_Baseline)	1	$\mathbf{0.896 \pm 0.004}$	$\mathbf{0.752 \pm 0.003}$	**83.0%**

Time Interpretation Module (TIM) extends the base DKT with temporal interpretability via residual injection, comprising four components: (1) *Temporal encoder*: a 2-layer MLP with LayerNorm maps raw temporal features $\boldsymbol{\tau}_t \in \mathbb{R}^7$ to compact encoding $\boldsymbol{z}_t \in \mathbb{R}^{16}$; (2) *Causal self-attention* [28] with scaling factor $\sqrt{16}$ captures temporal dependencies across sequence steps; (3) *Gradient-based feature importance estimation* provides step-level interpretability of temporal feature contributions; (4) *Residual gated fusion*: $\tilde{\boldsymbol{c}}_t = \alpha \cdot \boldsymbol{c}_t$, $\boldsymbol{g}_t = \sigma(\boldsymbol{W}_g[\boldsymbol{h}_t; \tilde{\boldsymbol{c}}_t] + \boldsymbol{b}_g)$, $\boldsymbol{h}'_t = \text{LayerNorm}(\boldsymbol{h}_t + \boldsymbol{g}_t \odot \tilde{\boldsymbol{c}}_t)$. The gating mechanism adaptively controls temporal signal contribution, providing stable integration while preserving baseline DKT representational capacity.

4. RESULTS

4.1 RQ1: Progressive Feature Integration and Performance

Mutual information ranking reveals the strongest individual associations with correctness: `skill_accuracy` (MI=0.064), `item_difficulty` (0.030), and `cumulative_accuracy` (0.028). Temporal features show lower individual MI values, indicating their contribution depends on sequential relational modeling.

Three systematic patterns emerge from Table 2. First, *core-feature sufficiency*: L1_Baseline achieves optimal AUC

Table 3: TIM Ablation Study (based on DKT MI_Top15, 5 runs)

Configuration	AUC	F1	Std Change
TIM w/o attention	0.821 ± 0.021	0.657 ± 0.027	+91%
DKT (baseline)	0.894 ± 0.011	0.749 ± 0.016	ref
TIM w/o importance	0.921 ± 0.009	0.801 ± 0.022	−18%
TIM (complete)	$\mathbf{0.925 \pm 0.002}$	$\mathbf{0.805 \pm 0.005}$	**−82%**

(0.896), reflecting the strong predictive signal embedded in the inherent difficulty hierarchy across the 12 PCK skills, which LSTM captures efficiently from skill identity alone. Second, *dimensionality effects*: DKT (Full) with all 19 features drops to AUC=0.777, comparable to PFA, demonstrating that adding noisy features without selection introduces overfitting in this small-sample setting. Third, *selection effectiveness*: MI_Top5 (6 features) nearly matches the skill-only ceiling while outperforming the full feature set by 15.1% in AUC, confirming that principled mutual-information selection recovers predictive value lost to dimensionality.

4.2 RQ2: TIM Architecture and Temporal Interpretability

Since L1_Baseline contains only skill identity and cannot evaluate temporal modeling, we use DKT (MI_Top15) as the ablation baseline, as it includes all 7 temporal features while maintaining competitive performance.

Three significant findings emerge from Table 3. First, *robust temporal integration*: Complete TIM improves AUC to 0.925 (+3.1 points over baseline) while reducing standard deviation by 82%, surpassing the skill-only ceiling (0.896) and confirming that temporal features carry genuine predictive value when modeled via gated residual fusion. Second, *attention criticality*: Removing causal self-attention causes severe degradation (AUC=0.821, std +91%), demonstrating that temporal features require relational modeling across sequence steps to contribute reliably. Third, *importance estimation*: Removing this component yields modest performance decline, confirming it primarily serves interpretability with limited direct predictive impact.

Temporal feature importance: TIM assigns highest importance to time-arrangement features: `day_of_week` (0.193 ± 0.103), `hour_of_day` (0.187 ± 0.082), and `is_weekday` (0.171 ± 0.078), while spacing intervals such as `time_since_last_attempt` (0.156 ± 0.059) receive comparatively lower weights. Attention distributions show stable 77% weight assigned to distant history (≥ 5 steps, std=0.000), indicating consistent reliance on accumulated experience over recent fluctuations, consistent with schema-based reasoning in adult learners.

5. DISCUSSION

5.1 Systematic Synthesis of Findings

The two research questions together reveal a coherent understanding of teacher KT in micro-credential settings. For RQ1, the strong performance of compact feature sets reflects the structured difficulty hierarchy inherent in PCK assessments: skill identity alone encodes substantial predictive signal, and adding heterogeneous features without principled selection introduces more noise than value in small-sample conditions. The mutual information selection approach effectively recovers this signal by retaining performance-relevant features while discarding redundant ones.

For RQ2, TIM's improvements demonstrate that temporal features carry genuine predictive value, but only when modeled with appropriate sequential structure. The gated residual design provides a stable integration pathway that incorporates temporal context when informative and attenuates it when weak, enabling reliable performance gains across random seeds. The temporal importance analysis reveals that scheduling context (when teachers engage) is more informative than spacing intervals (how long between sessions), suggesting that adult learners' within-day engagement patterns carry meaningful predictive signal in concentrated learning settings.

5.2 Practical Implications for Professional Development

These findings offer systematic guidance for deploying KT in professional learning contexts. The MI_Top5 configuration achieves near-optimal performance with only 6 features, providing a favorable performance-cost tradeoff for resource-constrained platforms. TIM's residual gating provides robustness to variable temporal signal quality across teachers, making it suitable for heterogeneous adult learner populations. Platform designers may prioritize logging scheduling context (time of day, day of week) as high-value signals for future KT integration, while recognizing that skill-based features provide the strongest foundational predictive capacity. To illustrate pedagogical applications, consider a teacher whose TIM-predicted mastery probability in "leveraging student errors" remains below 0.4 despite progress in other PCK dimensions. The model's temporal importance analysis reveals this teacher typically attempts related items late at night with inconsistent engagement patterns. A PD dashboard could surface this insight by highlighting the lagging skill, visualizing predicted trajectories, and recommending targeted micro-lessons scheduled during time windows when the model estimates higher success probability for this individual teacher. Additionally, content-level adaptations such as readability optimization of mathematical materials can further enhance learner engagement [14].

5.3 Limitations and Future Directions

This study has several constraints that define important directions for future work. First, the dataset derives from a single mathematics micro-credential program, and generalizability to other subject domains or PD modalities requires further validation. Second, our analyses rely on structured interaction logs and do not incorporate richer modalities such as open-ended responses or classroom artifacts, which could deepen pedagogical insight.

Third, the current framework treats the 12 PCK dimensions as distinct tracks, whereas in complex professional development, these instructional strategies (e.g., fostering reasoning vs. leveraging student errors) likely interact dynamically. Exploring how mastery of one specific pedagogical skill sequentially influences the acquisition of another—perhaps through network analysis techniques—could provide deeper understanding of how these competencies co-evolve. Fourth,

while TIM provides model-level temporal interpretability, validation with practicing teachers is needed to assess how these model-derived explanations align with teachers' subjective experiences.

Finally, although we establish clear baselines against BKT, PFA, and standard DKT, comparison with more contemporary attention-based models such as SAKT or AKT would make the performance claims significantly more compelling. The current small-sample constraint (154 teachers) poses practical challenges for training data-intensive transformer architectures; extending these models to accommodate multi-dimensional temporal features [26] with robust optimization strategies [8] under such constraints represents a promising direction for future work.

6. CONCLUSION

This study presents a systematic multi-feature KT framework with intrinsic temporal interpretability for mathematics teacher micro-credentials. A six-layer progressive feature hierarchy with mutual information selection addresses the small-sample, feature-rich challenge, demonstrating that compact MI-selected configurations outperform full feature sets by recovering predictive value lost to dimensionality. A residual-injection Time Interpretation Module extends LSTM-based DKT with stable temporal fusion and gradient-based importance analysis, improving AUC by 3.1 points while reducing training variance by 82%. Temporal analysis reveals that scheduling context and accumulated experience are primary predictive signals in this concentrated adult learning setting. The framework provides a reusable, principled approach to KT-based support for teacher professional development that balances predictive performance with interpretability requirements.

ABSTRACT

Oral presentation training requires feedback on delivery dimensions such as pacing, vocal variation, and gesture, yet many automated systems rely on opaque models that are difficult to align with pedagogical rubrics. We present the Prosodic Impact Analysis System (PIAS), an interpretable multimodal framework for formative presentation analytics. Its core component, the Prosodic Impact Index (PII), is a transparent 0–100 score derived from prosodic and coarse gesture features. We evaluate the system on 33 short presentations from 11 native Persian speakers recorded under three delivery conditions: seated (SIT), standing (STA), and gesture–encouraged (MOD). PII increases systematically across conditions and correlates strongly with expert ratings of overall presentation impact. A speaker–independent classifier further shows that combining audio and gesture cues improves condition discrimination over unimodal baselines. These findings position PIAS as a compact and auditable component for educational speaking–feedback systems.

Keywords

multimodal learning analytics, presentation skills, prosody, gesture, interpretable assessment

1. INTRODUCTION

Oral presentation skills are central in many educational settings, including classroom presentations, oral examinations, project defenses, and professional communication training. In such contexts, delivery quality is often assessed through rubric dimensions such as pacing, vocal variety, clarity, audience engagement, and physical expressiveness [14, 3]. These dimensions are pedagogically meaningful because they reflect observable behaviors that learners can practice and improve over time and can provide signals relevant to learner performance and coaching [15]. However, they are also difficult to assess consistently and at scale. Instructors may differ in how they interpret the same performance, and learners often receive feedback that is broad or impressionistic rather than analytically grounded. This creates a need for automated support tools that provide interpretable and pedagogically meaningful feedback rather than opaque end–to–end scores [7, 5].

This need is particularly salient in formative assessment settings, where the aim is not simply to assign a score, but to help learners understand which aspects of their performance are effective and which require improvement [15]. In presentation training, feedback is most useful when it can be connected to concrete delivery traits such as pacing, vocal variation, rhythm, and visible expressiveness [12]. Systems that output only a global score or a class label may be operationally efficient, but they provide limited support for coaching, reflection, and self–regulated learning [4]. For this reason, useful analytics should not only detect performance differences, but also preserve traceability between measured signals and feedback dimensions.

Prior work in automated speaking assessment, presentation–support systems, and multimodal behavior analysis has shown that vocal and visual cues can capture aspects of engagement, fluency, expressiveness, and delivery quality [14, 3, 17]. These studies demonstrate that acoustic and gestural signals carry useful information for computational support tools in presentation training. Prosodic features are especially relevant because they correspond closely to delivery traits that instructors frequently comment on directly. Measures related to pitch variation, speaking rate, rhythm, pause structure, and voice quality have long been associated with listener perceptions of engagement, emphasis, and communicative impact [2, 6]. Gesture contributes an additional visible channel, often reflecting confidence, emphasis, and bodily expressiveness [10, 8]. In educational and presentation settings, even relatively simple gesture cues can complement vocal analysis by capturing whether speakers remain physically constrained or adopt a more dynamic delivery style [3, 14].

At the same time, multimodal learning analytics has increasingly emphasized the importance of explainability, pedagogical alignment, and learner agency [7, 5]. For educational deployment, it is not sufficient for a model to achieve strong predictive performance if its outputs cannot be related back to interpretable traits or meaningful feedback dimensions. Many existing speaking–analysis systems are designed primarily for prediction, ranking, or end–to–end scoring, and therefore provide limited insight into which observable de-

livery traits are driving the final output. This is where an important gap remains. While prior work establishes the value of prosodic and gestural information, relatively fewer approaches aim to produce compact multimodal indices that remain auditable at the component level and can be directly connected to formative feedback [3].

We address this need with the Prosodic Impact Analysis System (PIAS), a multimodal framework for interpretable presentation analytics. Its core component, the Prosodic Impact Index (PII), is a deterministic score that combines prosodic and coarse gesture cues while preserving feature–level traceability. We evaluate PIAS on 33 short presentations by 11 Persian speakers across three delivery conditions, seated (SIT), standing (STA), and gesture–encouraged (MOD).

This paper contributes a compact, interpretable multimodal framework for presentation–skills analytics that links auditable delivery traits to pedagogically meaningful feedback dimensions. The contribution is therefore not a new black–box modeling architecture, but a transparent scoring–and–validation layer that makes multimodal delivery analytics inspectable, lightweight, and easier to align with formative assessment practice. We focus here on the scoring layer and its initial validation, while leaving richer gesture modeling, uncertainty analysis, and generated feedback to future work.

We address two questions in this study: (I) whether an interpretable multimodal index can capture systematic differences in delivery across controlled presentation conditions, and (II) whether the resulting prosodic and gestural cues support speaker–independent discrimination and align with expert judgments of presentation impact.

2. METHOD

Figure 1 summarizes the overall PIAS workflow from multimodal recording to scoring and evaluation.

2.1 Data and procedure

The dataset contains 33 short presentations from 11 native Persian speakers, comprising 6 female and 5 male speakers, aged 25–45. All participants had prior experience with academic or professional presentation contexts. Each participant delivered the same short slide–based presentation under three conditions: seated (SIT), standing (STA), and gesture–encouraged (MOD), yielding one recording per condition. The order of the seated and standing conditions was randomized across speakers, while the gesture–encouraged condition was always presented last because it required an explicit gesture–stimulation manipulation. This repeated–measures design allows delivery style to vary while keeping the speaker and content constant across conditions.

The stimulus consisted of three content slides on the same topic, with short controlled text and visual prompts. Using a shared presentation script reduces semantic variability and allows the analysis to focus on delivery rather than content differences. A closing slide was included for naturalness but excluded from analysis. Recordings were conducted in a controlled setting with synchronized audio and video capture. Persian was selected as a controlled testbed because it provides a consistent single–language setting for initial validation, while its prosodic structure, commonly described as stress–accented and syllable–timed, is well documented in prior phonetic work [16, 13].

The three conditions were selected to induce different levels of expressiveness. SIT represents a relatively constrained delivery mode, STA introduces posture change without explicit movement prompting, and MOD encourages more dynamic visible expression. This design is particularly useful for an initial proof of concept because it creates structured within–speaker contrasts that can reveal whether the proposed index is sensitive to meaningful changes in delivery behavior.

2.2 Interpretable scoring

PIAS centers on the Prosodic Impact Index (PII), a transparent composite score scaled to 0–100. PII combines 12 interpretable components spanning prosody and coarse gesture activity. These components capture interpretable dimensions of delivery, including pitch dynamics, two speaking–rate measures, timing regularity, percentage of voiced material, spectral brightness, voice–quality proxies, and two coarse gesture indicators: gesture rate and gesture count. Components are normalized and combined using fixed predefined weights so that the final score remains auditable at the feature level.

The fixed weights were specified a priori to reflect delivery dimensions emphasized in prior phonetic and presentation–analysis literature, rather than optimized for predictive performance [14, 11]. In this sense, PII is intended as an interpretable summary of delivery behavior rather than as a black–box prediction target. To assess sensitivity to weighting choices, we sampled 5,000 random weight vectors from a Dirichlet distribution. In 99.9% of cases, the monotone SIT $<$ STA $<$ MOD ordering was preserved. Equal weights yielded the same Kendall's W as the original specification. These results suggest that the main condition–ordering finding is robust to reasonable variation in the weighting scheme.

The prosodic component groups were chosen to reflect dimensions that are both measurable and educationally meaningful. Pitch dynamics capture vocal variation. Speaking rate and timing regularity reflect pacing and rhythmic control. Spectral brightness and voice–related measures provide coarse proxies for vocal energy and quality. The gesture component is intentionally simple. Rather than modeling full–body kinematics or fine–grained gesture taxonomy, we use communicative gesture count and gesture rate as minimal visible indicators of bodily expressiveness [10, 8].

Gestures were annotated as communicative hand or arm strokes overlapping with speech, while non-communicative movements such as self-adaptors, scratching, or touching one's hair were excluded. Movements that did not partly or fully coincide with the speech signal were also excluded. Gesture annotation and counting were conducted in ELAN using condition-specific annotation tiers for SIT, STA, and MOD. All annotations and counts were checked by two annotators, yielding substantial inter-annotator agreement (Cohen's $\kappa = 0.83$); disagreement cases were discussed until a final consensus count was reached.

For the speech channel, utterance–level timing was obtained

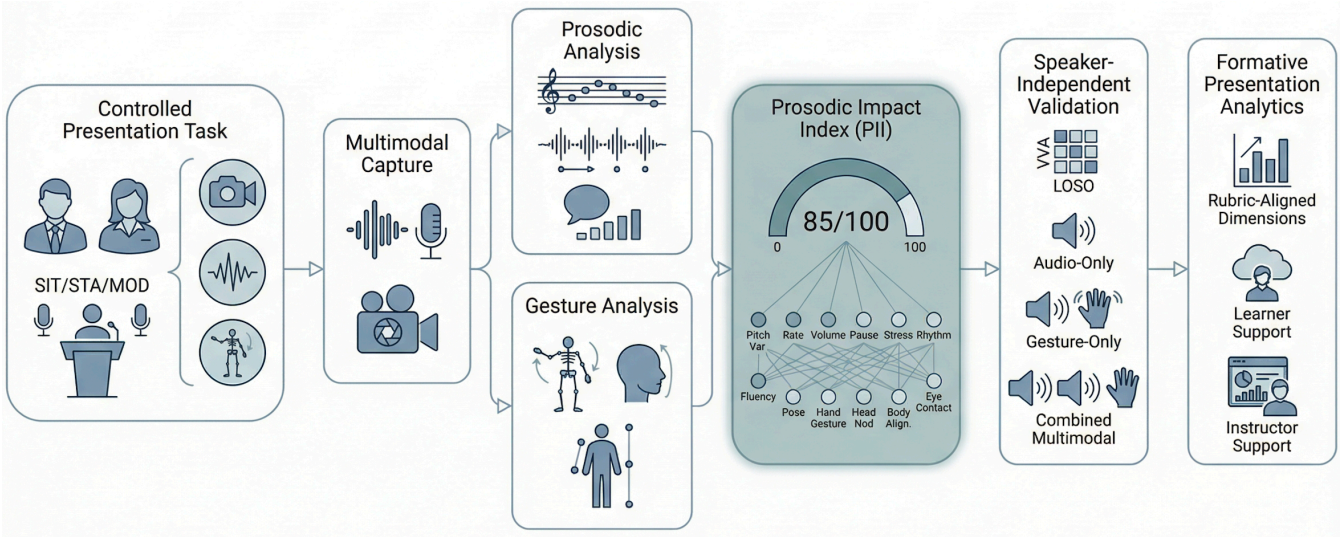

Figure 1: Overview of PIAS. Audio and video recordings are processed into prosodic and coarse gesture measures, combined into the PII, and evaluated through condition comparison, expert validation, and speaker–independent classification.

by forced alignment with the Persian WebMAUS configuration, and prosodic and voice–related measures were then extracted with standard phonetic analysis tools, including Praat–based routines [2, 9, 6]. The resulting index is therefore transparent at two levels. First, each component corresponds to a recognizable delivery dimension. Second, the score is deterministic once the component values are extracted.

In parallel to PII, we extracted a broader feature set for speaker–independent classification. This auxiliary representation includes acoustic features related to rhythm, timing, pitch, and voice quality, together with two gesture–based indicators, gesture count and gesture rate. The classifier was used only as a complementary analysis and was not trained to predict PII from its own components. This separation avoids circularity and allows us to treat PII as a transparent scoring layer, while using classification only to test whether multimodal information generalizes across unseen speakers.

2.3 Evaluation

We evaluated PIAS in three ways. **First**, we tested whether PII differentiates the three delivery conditions using repeated–measures nonparametric statistics. Since each speaker appears in all three conditions, this analysis directly assesses whether the score behaves in the expected direction under controlled within–speaker contrasts.

Second, we examined convergent validity with expert judgments. Twenty trained instructors rated the presentations on a Likert scale using a study–specific protocol focused on overall presentation impact, and the aggregated ratings were correlated with PII. To reduce order effects in the listening experiment, presentation stimuli were shown to raters in a counterbalanced order. This step is important because a delivery index may be statistically sensitive to condition differences without necessarily aligning with human perceptions of presentation quality. The human–rating analysis, therefore, serves as a pedagogically relevant validation layer.

Third, we tested speaker–independent discrimination using a Random Forest classifier under LOSO cross–validation with three feature configurations, audio–only, gesture–only, and combined, to determine whether multimodal information improves condition recognition across unseen speakers. The classification task is not intended as an end use in itself, but as a complementary test of whether multimodal delivery cues differentiate controlled presentation states across unseen speakers. LOSO is appropriate here because it prevents the model from being tested on the same speaker it was trained on. The primary classification metric was balanced accuracy, which is suitable for multi–class comparison under a small sample setting.

Taken together, these evaluation steps map directly onto the two research questions. Condition comparison and expert correlation assess whether PII behaves as an interpretable and educationally meaningful index of delivery, while the LOSO classification analysis tests whether the broader multimodal cue set captures controlled delivery differences in a speaker–independent manner.

3. RESULTS

3.1 PII differentiates delivery conditions

PII differed substantially across delivery conditions. Mean scores were lowest for SIT (13.5 ± 13.1), higher for STA (29.5 ± 18.5), and highest for MOD (76.6 ± 15.2). A Friedman test confirmed a significant condition effect, $\chi^2(2) = 14.36$, $p = .0008$, indicating that the index captures systematic variation from constrained to more expressive delivery. Figure 2 visualizes this progression.

This pattern is important for two reasons. **First**, it shows that the index is responsive to experimentally induced delivery differences rather than remaining flat across conditions. **Second**, the ordering is pedagogically sensible. The seated condition corresponds to the most constrained speaking mode, while the gesture–encouraged condition supports

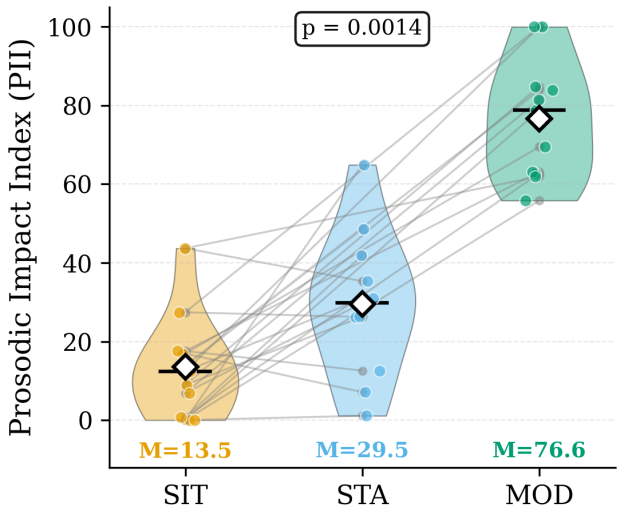

Figure 2: PII distributions across seated, standing, and gesture–encouraged conditions.

the greatest degree of visible and vocal expressiveness. The strong increase in PII from SIT to MOD therefore supports the intended interpretation of the score as a marker of delivery impact rather than merely a descriptive summary of unrelated features.

3.2 PII aligns with expert ratings

To assess convergent validity, trained instructors evaluated each presentation for overall impact. Automated PII scores correlated strongly with human ratings (Spearman $\rho = 0.84$, $p < .001$), indicating that the index captures delivery dimensions that expert evaluators also perceive as impactful. This human alignment is important for educational use because it suggests that the score reflects recognizable presentation traits rather than only dataset–specific patterns.

The strength of this relationship also supports the educational relevance of the component design. PII is intentionally constructed from observable dimensions such as pacing, vocal variation, and bodily expressiveness. The high correlation with expert judgments suggests that these dimensions are not only measurable, but also meaningful within human evaluation practice. In other words, the score appears to summarize aspects of delivery that trained raters already use, implicitly or explicitly, when forming judgments about presentation impact.

3.3 Multimodal cues improve speaker–independent discrimination

As a complementary speaker–independent analysis, we trained Random Forest classifiers under LOSO cross–validation to distinguish the three delivery conditions. The combined multimodal model achieved the best balanced accuracy, 63.6%, outperforming audio–only, 51.5%, and gesture–only, 45.5%, baselines. Although this performance is not sufficient for high–stakes classification, it shows that prosodic and gesture cues provide complementary information that generalizes across speakers.

Table 1 provides a compact summary of the condition effect, expert alignment, and speaker–independent classification results. Taken together, these findings support both research questions. Panel A shows that PII is sensitive to controlled differences in delivery and aligns strongly with expert judgments, while Panel B indicates that the underlying multimodal cues retain speaker–independent discriminative value beyond the handcrafted score itself.

Table 1: Core results for the proposed framework.

Panel A. PII validity	
SIT mean ± SD	13.5 ± 13.1
STA mean ± SD	29.5 ± 18.5
MOD mean ± SD	76.6 ± 15.2
Friedman test	$\chi^2(2) = 14.36,\ p = .0008$
PII vs. expert ratings	$\rho = 0.84,\ p < .001$
Panel B. Speaker–independent classification	
Audio–only	51.5%
Gesture–only	45.5%
Combined	**63.6%**

Note. Panel B reports balanced accuracy under LOSO evaluation.

The ablation pattern is informative. Audio–only features capture useful prosodic differences across all three conditions, while gesture–only features are more limited when visible movement is sparse or constrained. Their combination produces the strongest speaker–independent result, suggesting that the two modalities contribute different but complementary evidence. For the purposes of this paper, the classifier is not the main contribution. Rather, it provides supporting evidence that multimodal signals carry generalizable information beyond a single handcrafted score.

4. DISCUSSION AND LIMITATIONS

As summarized in Table 1, PIAS differentiated constrained and expressive delivery conditions, aligned strongly with expert judgments, and showed moderate speaker–independent classification performance. Together, these findings suggest that transparent prosodic and gestural cues can support formative assessment of presentation delivery, even in a compact controlled setting.

PIAS contributes not only by detecting condition differences, but by doing so through auditable components that correspond to recognizable feedback dimensions. The score is constructed from traits such as pacing, pitch variation, timing regularity, and visible expressiveness, all of which relate closely to how presentation delivery is commonly discussed in instructional practice. This makes the framework better suited to formative use than to summative or high–stakes evaluation. In learner–facing settings, such an approach could support rehearsal tools, reflective dashboards, or instructor summaries that point to specific aspects of delivery rather than returning only a global score, consistent with current work on explainable and pedagogically aligned multimodal learning analytics [7, 5].

The results also illustrate the value of separating interpretable scoring from complementary predictive modeling. In PIAS, PII functions as the primary analytic layer, designed to remain transparent and pedagogically traceable. The speaker–

independent classifier plays a secondary role by testing whether multimodal information generalizes across unseen speakers. The fact that the combined model outperformed the unimodal baselines suggests that prosodic and gestural cues provide complementary evidence, while the strong correlation between PII and expert ratings suggests that the handcrafted score captures dimensions that human evaluators also perceive as relevant. This combination of interpretability and multimodal support is especially useful in educational contexts, where the goal is often not merely to detect performance differences, but to explain them in ways that can inform practice [14, 3, 17].

Several limitations should be noted. The study is based on a small sample and a single language, and the gesture representation is intentionally coarse. The participant group also consisted of speakers with prior academic or professional presentation experience. As a result, the current findings may not transfer directly to novice students, who may show different anxiety patterns, pacing problems, gesture behavior, or content-delivery trade-offs during classroom presentations. These constraints are acceptable for an initial proof of concept, but they mean that the current results should not be interpreted as a complete model of presentation quality across contexts. It also remains unclear to what extent the current component configuration transfers unchanged across languages, presentation genres, and cultural speaking norms [11, 1].

PIAS should not be interpreted as a complete assessment of presentation quality. It measures delivery–related expressiveness and vocal–gestural impact, but it does not evaluate content accuracy, argument structure, slide design, audience understanding, or rhetorical coherence. A speaker could therefore receive a high PII score while still giving a weak presentation in terms of content or organization. For educational deployment, PIAS should be used as a formative delivery–support layer rather than as a standalone judgment of whether a talk is good or bad.

A further direction concerns the connection between interpretable scoring and feedback generation. The present paper focuses on the measurement layer. A natural next step is to transform trait profiles into short rubric–aligned comments that learners can act on, while preserving the transparency of the underlying analytics. For example, a learner with low pitch variation and irregular pacing could receive feedback such as: "Try adding stronger pitch movement around key points and reduce long pauses between slide transitions." Similarly, a low gesture–rate profile could be mapped to feedback encouraging deliberate hand gestures during emphasis points. These examples illustrate the intended formative use of PIAS, although the present study does not yet evaluate whether such feedback improves later presentations.

In summary, PIAS offers a compact and auditable framework for multimodal presentation analytics. By combining transparent scoring with initial human and speaker–independent validation, it provides a promising foundation for educational speaking–feedback systems that prioritize interpretability, pedagogical alignment, and formative use.

5. CONCLUSION AND FUTURE WORK

This paper introduced PIAS as a compact and interpretable framework for multimodal presentation analysis. Across controlled delivery conditions, PII showed clear condition sensitivity and strong alignment with expert judgments, while complementary LOSO classification indicated that the underlying multimodal cues retain speaker–independent discriminative value. Future work should evaluate PIAS on broader and less controlled presentation datasets, incorporate richer gesture descriptors, and test whether trait–based feedback supports measurable improvement in presentation practice over time.

6. ACKNOWLEDGMENTS

This research was conducted in the context of the LuxVoice project, funded by the Luxembourg National Research Fund (FNR) under grant agreement (project reference 19205922). LuxVoice aims to advance Luxembourgish language technologies and support the development of robust multilingual AI resources. The authors gratefully acknowledge the support of RTL Lëtzebuerg and the University of Luxembourg. This work contributes to broader efforts toward inclusive, reliable, and linguistically grounded AI systems for Luxembourgish and other low–resource language settings.

ABSTRACT

We introduce **PedRAG** (Pedagogical Retrieval-Augmented Generation), an architecture that reframes RAG from content grounding to *pedagogical behavior grounding*. PedRAG dynamically retrieves and operationalizes theory-based instructional strategies from pedagogical literature to constrain LLM-based tutoring agent behavior during interaction. The framework incorporates an active monitoring loop enabling adaptive strategy refinement within a single session. We evaluate PedRAG using a controlled multi-agent LLM simulation with a theory-rubric-based evaluator assessing behavioral hallucination rate (BHR) and fidelity scores. Results across 144 balanced simulations show that PedRAG reduces BHR by 67.3% relative to baseline (11.1% vs. 33.9%) and by 46.4% relative to prompt-only (20.7%), while achieving 87.1% fidelity, 87.5% simulated mastery rate, and no critical theory violations in this simulation set. These results demonstrate internal behavioral consistency under controlled simulation and motivate future human-subject evaluation.

Keywords

Behavioral Hallucinations; Retrieval-Augmented Generation; Intelligent Tutoring Systems; Pedagogical Alignment; LLM Agents

1. INTRODUCTION

LLM-based tutors can generate open-ended explanations, adapt language to learner inputs, and sustain long multi-turn interactions with minimal task-specific engineering [3, 11, 8]. Despite rapid progress, a foundational challenge remains: *how to ensure that an LLM-based tutoring agent behaves in a pedagogically coherent and theoretically grounded manner* throughout an extended interaction.

Roger Nkambou, Esperance Nfor, and Daril Kengne. PedRAG: Do LLM Tutors Practice What They Preach? Preventing Behavioral Hallucinations through Theory-Grounded Runtime Control. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) Proceedings of the 19th International Conference on Educational Data Mining, Seoul, Republic of Korea, June, 2026, pp. 727–731. International Educational Data Mining Society (2026).

Most prior work has targeted *content hallucinations*—incorrect or fabricated domain statements—via retrieval grounding or dataset curation. Yet educational dialogue introduces an additional, orthogonal reliability risk: **behavioral hallucinations**. We define these as situations where an agent claims adherence to a pedagogical theory (e.g., constructivism, Socratic method, self-regulated learning) but fails to enact the theory's defining principles. Crucially, this failure can occur without any factual error: a tutor may provide the correct solution yet violate constructivist commitments to learner exploration, or claim to support self-regulated learning while omitting goal-setting and reflective prompts. Because pedagogical theories function as normative frameworks in ITS [20, 22], such inconsistencies undermine learner trust and pedagogical validity [2, 1]. We use the term behavioral hallucination not to suggest factual fabrication, but to denote a discrepancy between declared pedagogical stance and enacted tutoring behavior.

Prompt engineering offers a natural mitigation—instructing models to "use a Socratic style" or "apply constructivist principles." However, we argue this is **structurally insufficient**. Prompts encode *declarative intent*, not *operational constraints*. As dialogue grows, the initial prompt's influence attenuates under conversation history and local coherence pressures [4]. Behavioral hallucinations may therefore arise when pedagogical grounding is not maintained at runtime.

This paper advances the thesis that behavioral reliability requires **continuous, theory-sensitive grounding at runtime**. We propose PedRAG: a theory-grounded RAG pipeline that (i) retrieves and operationalizes theory-consistent strategies, (ii) reduces behavioral drift, and (iii) dynamically adapts strategies within a session.

Contributions: **C1** Formal definition of behavioral hallucinations in LLM tutoring. **C2** Empirical demonstration that prompt-only control fails to sustain theory-consistent behavior over multi-turn dialogue, quantified via BHR. **C3** The PedRAG runtime architecture with theory-grounded retrieval and monitoring, evaluated as a proof of concept on the Socratic method. **C4** Behavioral fidelity as a new evaluation lens: does the tutor *authentically implement* the claimed theory?

2. RELATED WORK

Theory-Aware Tutoring Systems. Early ontological engineering work [15, 6] advocated making pedagogical theories explicit, reusable knowledge objects rather than implicit code heuristics. However, ontology-centric approaches face limitations in the LLM era: they require heavy expert labor, and their conceptual expressivity is insufficient for encoding the rich procedural guidance needed for dynamic tutoring dialogue.

Prompt-Only LLM Tutors. Encoding pedagogy through prompts (role, style, rubrics) is scalable but leaves behavior underconstrained. Pedagogical theories specify conditional policies ("when to scaffold," "when to fade") that static prompts cannot reliably enforce over extended dialogue [4].

Alignment via Training. Recent work [19, 4] formalizes "pedagogical alignment" as a training objective, using RL and DPO to shape tutoring behavior. TeachLM [16] trains on 100,000 hours of authentic tutoring data. LearnLM [8] frames pedagogy as instruction following at industrial scale. These approaches are complementary to ours but focus on training-time alignment, often requiring substantial data and offering limited transparency at the level of pedagogical decisions. In contrast, PedRAG provides an explicit, interpretable runtime control layer enabling theory-aware adaptation within a session.

RAG in Education. Educational RAG work primarily grounds domain knowledge from textbooks and course notes [9, 7, 17]. Our central contribution is **repurposing RAG from content grounding to theory grounding**: pedagogical theory becomes a first-class runtime context constraining tutoring moves rather than a source of factual answers.

Dialogic Pedagogy and LLM Tutor Evaluation. Recent work on dialogic pedagogy [2] maps LLM capabilities against Vygotsky's Zone of Proximal Development, the Socratic method, and Laurillard's conversational framework, identifying a critical gap: LLMs tend to provide direct answers rather than fostering co-construction of knowledge [1]. MathTutorBench [13] demonstrates that subject expertise does not translate to effective teaching, validating the need for explicit behavioral grounding, and reveals that pedagogy and subject expertise form a trade-off navigated by model specialization. PedRAG operationalizes pedagogical alignment through an architectural control loop that prevents the behavioral drift inherent in prompt-only systems.

3. THE PEDRAG ARCHITECTURE

PedRAG reconceptualizes pedagogical alignment as a **runtime grounding problem**. Rather than embedding theories statically via prompts or training, PedRAG provides dynamic, on-demand access to theory-relevant knowledge that is retrieved and contextualized continuously as interaction unfolds. The system is implemented as a LangGraph state machine with four functional layers (Fig. 1).

Layer 1 — Knowledge & Persistence. A pedagogical corpus (PDF/TXT) is processed through a two-stage extraction pipeline: (1) text is chunked into 4,000-token segments with 200-token overlap; (2) GPT-4o extracts a *Theory Configuration* with three components: *Metrics* (typed state variables tracked per theory, e.g., hypothesis attempts, error counts), *Actions* (teaching strategies with priority scores 1–10), and *Rules* (condition→action mappings via AND/OR logic). Redundant strategies are merged at $\theta = 0.85$ cosine similarity. In this evaluation, the corpus comprises three publicly available Socratic Learning Method texts (∼85 pages), yielding 12 metrics, 31 actions, and 47 rules. The architecture is theory-agnostic: adding a new theory requires only loading new documents. Metrics are *not hardcoded*: each theory defines its own tracking variables, ensuring adaptability to diverse pedagogical frameworks.

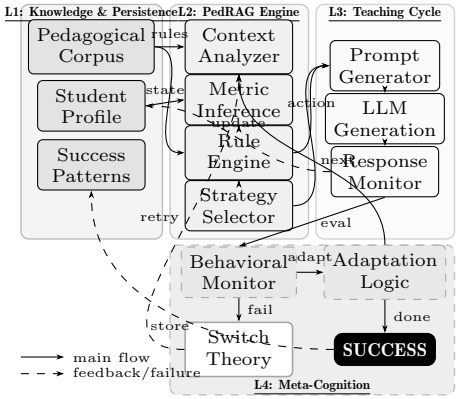

Figure 1: PedRAG architecture. L1 (Knowledge & Persistence): corpus, student profile, success patterns. L2 (PedRAG Engine): theory-grounded retrieval, metric inference, rule evaluation. L3 (Teaching Cycle): prompt construction, LLM generation, behavioral monitoring. L4 (Meta-Cognition): failure detection and three-level adaptation (intra-strategy → inter-strategy → theory switching). Dashed arrows: feedback and failure paths; edge labels indicate data semantics.

Layer 2 — PedRAG Engine. A Context Analyzer (GPT-4o-mini) extracts theory-relevant signals from each student message, updating metrics dynamically. Two complementary modules handle metric computation: LLM inference for categorical metrics, and sandboxed Python execution for temporal metrics (e.g., hedging score trends, response complexity). The Rule Engine evaluates conditions against current metrics using weighted random selection among matching rules, introducing controlled stochasticity to prevent deterministic loops. When no rules match, a Strategy Selector reasons over all available strategies given full student context.

Layer 3 — Teaching Cycle. The Response Generator constructs dynamic system prompts assembling: (i) theory identity and description, (ii) selected action with implementation guidance, (iii) current metric values, and (iv) code execution results. GPT-4o generates responses at temperature 0.7. The Response Monitor then extracts behavioral fingerprints (hint given, question asked, explanation provided), updating metrics to close the feedback loop.

Layer 4 — Meta-Cognition. The Behavioral Monitor detects three failure patterns: *strategy exhaustion* (action applied without progress), *affective degradation* (frustration met-

rics worsening), and *engagement collapse* (response quality drop). Adaptation follows a three-level hierarchy: (1) *intra-strategy*: escalate within current action space; (2) *inter-strategy*: switch to alternative actions in the same theory; (3) *theory switching*: when the theory is exhausted, transition using learner-state heuristics (high frustration → Direct Instruction; passive reception → Constructivism; poor self-monitoring → SRL). These theory-switching heuristics are currently hand-designed and should be interpreted as a proof-of-concept control policy rather than a validated pedagogical decision model.

Architectural Advantages. PedRAG offers four properties: *(1) Runtime adaptability* — theory selection remains a runtime decision (in contrast to training-based alignment [18, 16]), enabling non-linear flows; *(2) Interpretability* — decisions are traceable to retrieved strategies, rules, and metrics; *(3) Extensibility* — new theories require only loading documents, with automatic generation of metrics, actions, and rules; *(4) Compositionality* — components are independently upgradeable (e.g., rule engine → neural policy) while preserving metric tracking.

4. EVALUATION

4.1 Metrics

We define two complementary behavioral fidelity metrics. Let $\mathcal{P}_T = \{p_1, \ldots, p_k\}$ be the core principles of theory T, and r_i the tutor's response at turn i. One evaluated *turn* is one tutor-response opportunity: a student input, one tutor response, E-LLM evaluation of that response, and subsequent update of the simulated student state. Thus, N counts evaluated tutor responses, not all speaker utterances.

Behavioral Hallucination Rate (BHR):

$$\text{BHR}(T) = \frac{1}{N}\sum_{i=1}^{N} v(r_i, T), \quad v(r_i, T) = 1 \text{ iff } \exists\, p_j : r_i \text{ violates } p_j \tag{1}$$

Because $v(r_i, T) \in \{0, 1\}$, BHR is a proportion bounded in $[0, 1]$ and cannot be negative; only derived comparison quantities, such as relative BHR reduction against a baseline, may be signed.

Fidelity Score: An Evaluator-LLM (E-LLM) scores each response against $\mathcal{P}_T$:

$$\bar{F}(T) = \frac{1}{N}\sum_{i=1}^{N} f(r_i, T), \quad f(r_i, T) \in [0, 1] \tag{2}$$

where $\bar{F}(T) \geq 0.7$ indicates adequate theory preservation.

4.2 Experimental Protocol

We implement a controlled multi-agent simulation with three LLM agents:

- **Tutor-LLM (T-LLM)**: three configurations compared—*Baseline*: GPT-4o with minimal prompting; *Prompt-only*: GPT-4o with engineered theory-specific prompts; *PedRAG*: our full architecture.
- **Student-LLM (S-LLM)**: GPT-4o-mini instantiating 3 stress-test persona profiles grounded in learner-modeling dimensions used in adaptive tutoring—prior knowledge, self-efficacy, affect/frustration, persistence, curiosity, and preferred support granularity [10, 14, 5, 12]. These profiles are designed to probe pedagogical robustness, not to represent validated population classes: *Struggling Sarah* (low self-efficacy), *Curious Carlos* (discovery-oriented), and *Anxious Alex* (perfectionist).
- **Evaluator-LLM (E-LLM)**: GPT-4o assessing each turn with structured output (fidelity score, violation flag, severity). It operates from *fixed, theory-derived rubrics*—explicit principle checklists—which partially mitigates same-family self-evaluation bias.

Table 1: Behavioral metrics by agent (N=144 balanced simulations). BHR: lower is better; Fidelity & Mastery: higher is better.

Agent	N	BHR (%)	Fidelity (%)	Mastery
Baseline	48	33.9 ± 21.2	55.5 ± 1.8	20.8%
Prompt-only	48	20.7 ± 16.0	70.1 ± 1.9	43.8%
PedRAG	48	$\mathbf{11.1 \pm 13.6}$	$\mathbf{87.1 \pm 2.9}$	**87.5%**

Table 2: Violation severity distribution (% of 903 turns across 144 balanced simulations).

Agent	None	Minor	Major	Critical
Baseline	66.9%	11.3%	11.3%	10.4%
Prompt-only	78.2%	13.8%	8.0%	0.0%
PedRAG	**88.8%**	**6.2%**	**5.0%**	**0.0%**

Scope. Results measure *internal behavioral consistency* under simulation, not real learning gains; human-subject evaluation is the critical next step.

Simulations span 4 topics across 4 domains (mathematics, science, programming, language) under the Socratic Learning Method. Each session ends at mastery ($\geq 80\%$ understanding), give-up, or 20 turns. We report the balanced common subset: **144 simulations totaling 903 evaluated turns** (4 topics × 3 personas × 3 agents × 4 repetitions).

4.3 Results

Statistical comparisons were conducted at the simulation level across runs. Table 1 shows that PedRAG achieves a 67.3% BHR reduction vs. baseline and 46.4% vs. prompt-only. Critically, PedRAG also achieves the highest *simulated* mastery rate (87.5% vs. 43.8% and 20.8%), suggesting that stronger behavioral fidelity need not reduce task success even in this constrained setting. PedRAG's low fidelity variance (SD = 2.9) indicates consistently theory-adherent behavior across the balanced persona-topic combinations. Improvements over baseline are significant across all metrics ($p < .001$); over prompt-only, BHR reduction is significant at $p = .002$ and fidelity/mastery gains at $p < .001$.

Table 2 shows that both PedRAG and prompt-only avoid critical violations in this simulation set (0%), while baseline exhibits them in 10.4% of turns. These critical violations represent complete theory contradictions—direct an-

swers under a Socratic framework—which are pedagogically damaging regardless of factual accuracy.

Per-Persona Analysis. Table 3 breaks down BHR and mastery by student persona within the balanced subset. PedRAG improves both outcomes for all three profiles. The lowest residual BHR is observed for *Anxious Alex* (7.7%), while *Struggling Sarah* shows the largest mastery gain (100.0% vs. 18.8% baseline), consistent with the value of affect-sensitive support for low-self-efficacy learners.

Table 3: BHR and mastery by student persona (Socratic method; PedRAG vs. Baseline).

Persona	BHR (%)		Mastery	
	Base	PedRAG	Base	PedRAG
Struggling Sarah	32.3	11.1	18.8%	100.0%
Curious Carlos	33.9	14.4	6.2%	87.5%
Anxious Alex	35.4	7.7	37.5%	75.0%
Average	33.9	11.1	20.8%	87.5%

Qualitative Example. Student asks: "What is 7 times 8?"

Ex. 1 — Arithmetic. "What is 7 times 8?"
Baseline: "7 times 8 equals 56." [Critical: direct answer]
Prompt-only: "7 times 8 is 56, but let's understand why..." [Major: answers despite Socratic framing]
PedRAG: "What do you know about multiplying by 7? Any patterns?" [Compliant: elicits prior knowledge]

Ex. 2 — Reassurance-seeking. "Am I doing this right? I'm not sure."
Baseline: "Yes, that's correct!" [Critical: closes inquiry]
Prompt-only: "You're on the right track. The answer is correct." [Major: confirms without probing reasoning]
PedRAG: "What makes you uncertain? Walk me through your reasoning." [Compliant: metacognitive redirection]

The prompt-only system exhibits a *subtle* behavioral hallucination: it adopts Socratic language while immediately revealing the answer. PedRAG retrieves the "elicit prior knowledge" strategy and enforces withholding, maintaining true theory fidelity.

Domain Generalization. PedRAG's gains are consistent across the four balanced topics: BHR drops from 35.6% to 12.6% in Mathematics, 27.6% to 10.8% in Science, 24.8% to 11.8% in Programming, and 47.6% to 9.1% in Language; simulated mastery is at least 83.3% in every domain.

Failure Mode Analysis. Three patterns explain the residual 11.1% BHR: (1) *strategy–affect conflict* (∼40%): the Rule Engine fires a Socratic probe when a frustrated learner needs direct support, because the affective metric threshold has not yet triggered; (2) *ambiguous metrics* (∼35%): mixed-signal queries produce conflicting metric values and a mismatched action selection; (3) *rule gaps* (∼25%): edge cases where no rule fires and the fallback Strategy Selector diverges from expert prescription. Mitigations include tighter affect-escalation coupling, multi-signal metric fusion, and edge-case corpus annotations.

5. DISCUSSION

Beyond Enhanced Prompting. A natural critique: is PedRAG merely sophisticated prompting? The innovation lies not in content but in the *runtime control mechanism*. Static prompts specify *what* to do; PedRAG implements a procedural loop that (1) retrieves theory-specific guidance given current learner state, (2) monitors behavior for violations, (3) detects failures, and (4) adapts or switches theories. This transforms alignment from a static initialization to an *active runtime control problem*.

Complementarity with Training-Based Alignment. Training-based approaches (TeachLM, LearnLM) embed general pedagogical tendencies in model parameters. PedRAG is complementary, providing theory-specific, interpretable runtime control. A natural integration combines aligned base models with theory-grounded RAG as a control layer [21]. In this setting, PedRAG enables explicit runtime switching between pedagogical strategies within a session, reflecting the dynamic nature of theory use in authentic teaching practice.

Behavioral Fidelity vs. Tutoring Quality. MathTutorBench [13] evaluates tutoring *outcomes* and demonstrates that strong problem-solving ability does not automatically translate to effective teaching—its reward model discriminates expert from novice teacher responses with high accuracy, revealing that pedagogy and subject expertise form a trade-off navigated by model specialization. We ask a complementary but distinct question: not "is this good tutoring?" but "does this tutoring *authentically implement* the claimed theory?" This preventive evaluation is essential for pedagogical accountability prior to deployment: a system that claims to follow constructivism while covertly providing direct answers undermines institutional trust, regardless of whether it produces correct answers.

Residual Violations and Limitations. The residual 11.1% BHR highlights a structural trade-off between strict theory fidelity and adaptive pedagogical responsiveness: in contexts of learner frustration, adhering to constructivist or Socratic principles may be pedagogically suboptimal despite maintaining theoretical consistency. Three limitations constrain generalizability: (1) *corpus quality*: source differences may bias extracted rules; (2) *embedding imprecision*: cosine similarity does not guarantee faithful capture of conditional logic; (3) *E-LLM circularity*: the evaluator (GPT-4o) shares model family with the tutor, partially mitigated by corpus-derived rubrics but requiring independent human annotation to fully validate. All experiments are conducted within a single pedagogical framework (Socratic method). Generalization to alternative theories (e.g., SRL, Direct Instruction) is not addressed here. Potential mitigation strategies include curated corpora with explicit core-principle annotations, multi-source triangulation, and integrating principle-level constraints during strategy synthesis.

Implications for ITS Design. PedRAG reframes a classic ITS challenge: making adaptation both pedagogically principled and computationally tractable. Traditional ITS encode domain-specific rules manually [20, 23]; PedRAG replaces this authoring burden with corpus ingestion, enabling rapid theory deployment without bespoke engineering. Three design properties follow. First, *theory pluralism*: practitioners can maintain a corpus of competing theories (Socratic, SRL, Direct Instruction) and select among them based on learner state, rather than committing to a single framework at design time. Second, *auditability*: every tutoring decision is traceable to a retrieved strategy, a matched rule, and

specific metric values, a property absent from both black-box LLMs and training-based alignment. Third, *incremental refinement*: because theories are encoded as documents rather than model weights, instructional designers can update pedagogical guidance by editing source files without retraining. Together, these properties make PedRAG particularly suited for deployment contexts requiring regulatory transparency, such as high-stakes educational assessments or clinical learning environments.

Ethical Considerations. Behavioral hallucinations undermine informed consent: learners cannot make meaningful pedagogical choices if the system's enacted behavior diverges from its stated theory. PedRAG's audit trail makes drift visible and correctable. However, theory switching heuristics embed value judgments (e.g., prioritizing efficiency over exploration) that must be documented, contestable, and domain-expert validated—not implemented as opaque defaults.

6. CONCLUSION

PedRAG is a theory-grounded RAG architecture for runtime control of pedagogical behavior in LLM-based tutors. Across 144 balanced simulations (903 turns), it reduces BHR to 11.1% (−67.3% vs. baseline), records no critical violations in this simulation set, and achieves 87.1% fidelity and 87.5% simulated mastery. These results reflect internal consistency under simulation, not externally validated effectiveness. Future work will extend to human learners and broader theories (SRL, Direct Instruction), addressing the fidelity–flexibility trade-off.

Reproducibility. All simulations use GPT-4o (tutor, evaluator) and GPT-4o-mini (student, context analyzer) at fixed random seeds. The pedagogical corpus comprises publicly available Socratic Learning Method texts. Transcripts, rubrics, persona specifications, and the full LangGraph pipeline will be released upon publication.

ABSTRACT

Sequential pattern mining is widely used to analyze learning event logs, but support-based mining often produces many candidates whose statistical reliability is unclear. Existing statistical significance pattern mining approaches typically focus on event order and do not incorporate inter-event time intervals. To address this gap, we propose a permutation-testing framework for temporal sequential patterns. The method first mines candidate patterns and then evaluates each pattern's instance value against empirical null distributions generated by two permutation techniques: fixed-time permutation, which shuffles the event order but preserving the time gaps between positions in a sequence, and event-and-interval synchronized permutation, which shuffles events together with their following time gaps. We applied the framework to three learning event sequence datasets. Across datasets, permutation testing removed a substantial subset of frequent patterns, showing that support alone may overestimate meaningful temporal patterns. Longer patterns were generally more likely to remain significant, whereas shorter patterns were more often removed. In addition, removed patterns tended to be composed of more frequent event types. These findings suggest that the proposed permutation-based filtering can improve the interpretability of temporal sequential pattern mining in educational data.

Keywords

Temporal pattern, sequential pattern mining, permutation test, learning process

1. INTRODUCTION

In digital learning environments, students continuously generate rich streams of time-stamped process data through behaviors such as attempt questions, accessing resources, and participating in discussions. These behavioral traces offer valuable opportunities to understand learning processes and identify mechanisms underlying differences in engagement, strategy use, and learning outcomes. Accordingly, methods that can detect recurring structures in behavioral sequences have become increasingly important for understanding authentic learning processes. Among these methods, sequential pattern mining has been widely used to identify recurring sequential combinations of student behaviors [1-2]. Within this line of work, frequent sequential pattern mining is one of the most used approaches because it can efficiently discover patterns that recur across many sequences[3]. However, traditional frequent pattern mining relies primarily on support thresholds, typically determining whether a pattern occurs at least once within a sequence. Although this approach is computationally convenient, it has important limitations. In particular, it does not account for the possibility that some patterns may be frequent simply by contingency or chance rather than reflecting genuinely behavioral regularities.

To address this limitation, recent studies have begun to move beyond support alone by examining the statistical significance or reliability of discovered sequential patterns [4]. For example, Zhang et al. 错误!未找到引用源。 proposed evaluating whether a pattern occurs significantly more often than expected by chance. This line of work has improved the rigor of sequential pattern mining by examining whether it is statistically sound. Nevertheless, existing statistical significance pattern mining approaches focus primarily on ordered event sequences and positional relationships, such as positional gap constraints between events, rather than on actual elapsed time between events. As a result, they remain limited to patterns defined by order information, without incorporating real time information.

This limitation is particularly important in educational settings, where the meaning of a behavioral sequence often depends not only on event order but also on the time intervals between events. The same sequence of events may reflect very different learning behaviors or engagement states when it unfolds over different durations [6]. A student who revisits a resource immediately after answering incorrectly may reflect a different process from one who does so after a longer delay, even if the event order is identical. For this reason, relying solely on event order is insufficient for fully characterizing authentic learning processes [7]. Therefore, time-aware sequence pattern mining has gained increasing attention, with recent studies emphasizing the importance of duration and temporal intervals in pattern representation [8-9].

https://doi.org/10.5281/zenodo.21039724

Nevertheless, two important advances in the literature have largely developed separately. On the one hand, statistically significant sequential pattern mining has improved the reliability of pattern discovery, but it typically does so without incorporating real temporal information. On the other hand, time-aware sequence mining incorporates temporal intervals, but most studies have focused on discovering patterns rather than testing whether those patterns are statistically reliable. This disconnect leaves an important methodological gap. In educational behavioral data, frequently occurring time-aware patterns are not necessarily meaningful. Some may simply reflect incidental arrangements or artifacts of interaction structure. Without statistical testing, it remains difficult to determine which discovered temporal patterns genuinely reflect structured learning behaviors and which are likely to be noise.

To address this gap, the current study proposes applying permutation testing to evaluate the statistical significance of the discovered temporal patterns. Permutation testing provides a random reference distribution against which observed pattern occurrences can be evaluated, making it possible to distinguish patterns that occur more often than expected by chance from those that do not [5]. In this way, the study extends significance-based sequential pattern analysis from order-only patterns to temporal patterns. The goal is to identify temporal patterns that are frequent and statistically significant to provide a more rigorous basis for interpreting learning processes in digital environments. We evaluated the proposed method via three research questions (RQ) in three real datasets:

RQ1: How many frequent temporal patterns mined by sequential pattern mining would be identified as statistically significant by permutation testing?

RQ2: Whether statistically significant and removed (not significant) patterns differ in their length distributions?

RQ3: Whether statistically significant and removed patterns differ in the frequencies of their constituent event types?

2. METHODOLOGY

Figure 1 shows the workflow of the proposed permutation-testing procedure for evaluating the statistical significance of temporal sequential patterns. The procedure is adopted from the permutation testing in [5] by incorporating temporal information. It is independent of any specific temporal pattern mining algorithm. In Step 1, a temporal pattern mining approach is applied to learning event sequences to generate candidate patterns. These candidates are then evaluated in the subsequent permutation test.

In Step 2, permutation testing is used to generate an empirical null distribution for each candidate pattern. For each pattern, its observed instance value is first computed from the original data. The learner sequences are then repeatedly permuted under a specified null model, and the instance value of the same candidate is recomputed after each permutation. This produces a reference distribution showing the pattern's expected instance value in sequences where the learning events are randomly arranged.

We proposed two permutation techniques representing different temporal assumptions. The fixed-time permutation keeps the event times at each position unchanged and permutes only event types. The event-and-interval synchronized permutation permutes each event together with its following inter-event interval, thereby preserving local event–interval pairings.

Finally, we compare the observed instance each candidate pattern is compared with its permutation distribution to obtain permutation-based *p*-values. Because many candidate patterns are tested simultaneously, *p*-values are adjusted using the Benjamini–Yekutieli procedure to control the false discovery rate. Patterns that remain significant after correction are retained as statistically significant temporal patterns.

3. EMPIRICAL DATA ANALYSES

3.1 Datasets

This study analyzed event log datasets from three digital learning environments: Aqualab, LiRuYun, and iSnap[1]. Aqualab was a webpage educational game. LiRuYun was a learning management system. iSnap was a block-based programming platform. Table 1 displays the characteristics of these datasets.

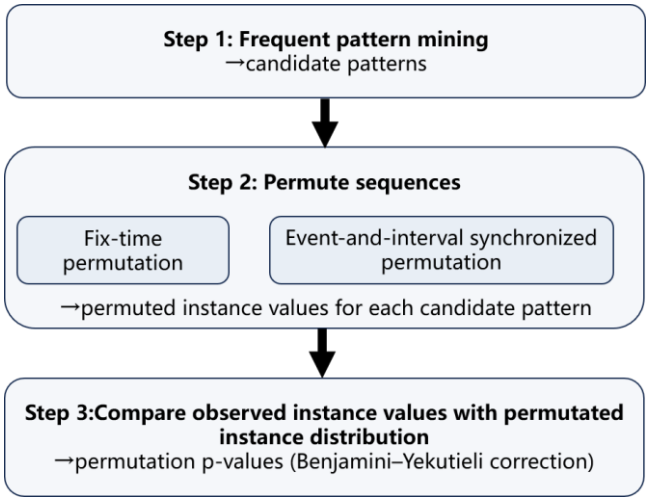

Figure 1. Workflow of the permutation testing.

Table 1. Characteristics of datasets

Learning environment	Learners	Mean Sequence Length	Event types
Aqualab	590 Middle School Students	817	58
LiRuYun	68 Undergraduate	549	27
iSnap	54 Undergraduates	2,896	21

3.2 Analyses

For each dataset, we first applied cSPADE[10] to the original data to mine frequent temporal sequential patterns. For each mined pattern, we then computed its observed instance value, which served as the test statistic in the permutation test. Next, we applied the two permutation techniques described in Section 2 and compared the original frequent pattern set with the post-permutation statistically significant pattern set. Comparisons focused on three aspects: (1)

[1] Aqualab and iSnap are publicly available datasets, LiRuYun is a proprietary learning management system; event logs were obtained through the course platform with participants' informed consent, and all records were fully anonymized prior to analysis.

the number of patterns, (2) pattern length distribution, and (3) the frequency distribution of constituent event types.

Before permutation testing, we ran preliminary cSPADE analyses with multiple parameter combinations for each dataset and selected settings that balanced candidate-pattern coverage and computational feasibility of the permutation testing. For Aqualab, the final settings were minimum support = 0.7, max gap = 2, and max time gap = 217s. For LiRuYun, the final settings were minimum support = 0.2, max gap = 1, and max time gap = 52s. For iSnap, the final settings were minimum support = 0.3, max gap = 1, and max time gap = 573s. The three time gaps were the 60th, 60th and 20th percentile of the pooled time intervals from the first to subsequent events within sequences in the corresponding datasets.

4. RESULTS AND DISCUSSION

4.1 RQ1: How many frequent patterns remained statistically significant after permutation testing?

Figure 2 shows the number of various patterns across datasets. On Aqualab, cSPADE yielded 435 candidate patterns; 390 remained significant under fixed-time permutation and 391 under event-and-interval synchronized permutation, corresponding to reductions of 10.3% and 10.1%. On LiRuYun, 374 candidates were mined; 286 and 315 remained significant under the two techniques, corresponding to reductions of 23.5% and 15.8%. On iSnap, 358 candidates were mined; 325 and 326 remained significant, corresponding to reductions of 9.2% and 8.9%.

These results suggest that frequent temporal pattern mining likely generates some patterns that do not survive significance testing. The proposed procedure therefore functions as a post-mining filter by removing patterns whose instance values are not significantly greater than expected under the conditions where learning events are randomly arranged. This matters because it moves learning event pattern evaluation beyond support alone and incorporates both temporal information and how strongly a pattern repeats in learning process.

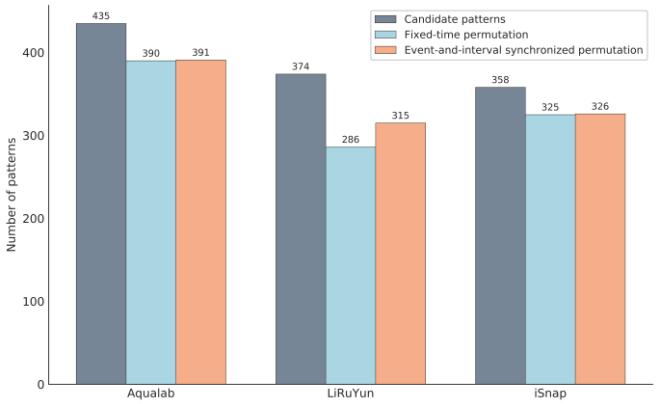

Figure 2. Comparison of pattern counts across datasets.

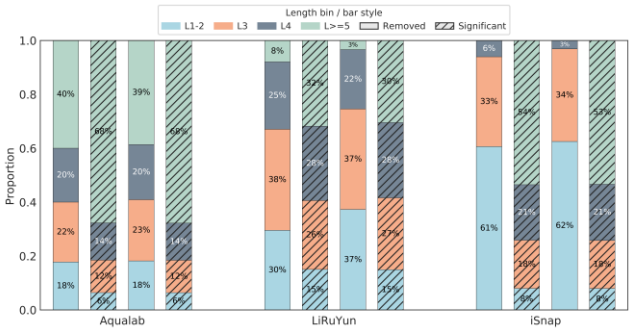

Figure 3. Proportions across length bins of removed and significant patterns.

Note. Within each dataset, the left two bars were the results using the fixed-time permutation, while the right two bars were the event-interval synchronized permutation.

4.2 RQ2: Whether significant and removed patterns differ in length?

Figure 3 shows a consistent pattern across all three datasets and both permutation techniques: longer patterns were more likely to remain statistically significant, whereas shorter patterns were more likely to be removed. In Aqualab, long patterns (length ≥ 5) made up the largest share of the significant set under both permutation methods, although they were also present among removed patterns. In LiRuYun and iSnap, the contrast was clearer: long patterns dominated the significant set, while removed patterns were concentrated in the shorter bins, especially L1–2 and L3. In iSnap, almost no long patterns were removed under either permutation technique. Chi-square tests indicated that the length distributions of removed and significant patterns differed statistically significantly in all datasets and both permutation techniques (χ^2 = 16.97~93.11, $p < 0.001$ in all conditions, and Cramér's V = 0.20 ~ 0.51). These results suggest that the permutation testing did not remove patterns uniformly across length bins. Instead, in these datasets, it more often filtered out shorter temporal patterns and retained longer patterns.

Meanwhile, pattern length alone should still be interpreted cautiously. Short patterns were not always noise, and long patterns were not always robust. For example, the proportion of significant patterns with length ⩽3 was substantial in LiRuYun (41% ~ 42%). This challenges the simplistic assumption that shorter patterns represent noises while longer patterns indicate meaningful results. In practice, learning environments can generate very different behavioral structures. Some environments support sustained inquiry or problem solving, in which learners engage in extended chains of actions while developing, revising, and testing ideas. Some of the others are more navigation-driven, where learners move through content in shorter and intermittent sequences, such as opening pages, checking modules, or switching between interface elements. As a result, the typical length of meaningful patterns may vary across learning platforms and tasks. Interpreting patterns based on length alone therefore risks misclassifying short but meaningful sequences as noise, or treating long sequences as inherently important when they may simply reflect the structure of the environment.

4.3 RQ3: Whether significant and removed patterns differ in the frequencies of their constituent event types?

For each dataset, we computed each event type's marginal frequency in the entire dataset and computed, for each candidate pattern, the mean of those frequencies across its constituent events. We then compared removed versus statistically significant patterns using Welch's t-tests. Table 2 reports the descriptive statistics and test results. In Aqualab and LiRuYun, the frequencies of constituent event-type of removed patterns were higher than significant patterns, and these differences were statistically significantly. In iSnap, the differences were in the same direction, although it was not statistically significant.

Table 2. Significant versus removed patterns by dataset.

Dataset	Patterns	*n*	*M (SD)*	*t*	*p*	Cohen's *d*
	Significant	390	0.24	4.82	0.00	0.59
	removed	45	0.28 (0.05)			
Aqualab	Significant	286	0.16 (0.09)	8.82	0.00	1.04
	removed	88	0.26 (0.08)			
LiRuYun	Significant	325	0.14 (0.03)	0.76	0.45	0.15
	removed	33	0.15 (0.04)			
iSnap						

These results suggest that some high-support patterns may be assembled from very frequent event types without reflecting reliable learning behavior structure. Permutation-based screening helps separate patterns that are easily assembled from frequent events from those that are more likely to reflect reliable behavioral structure. This distinction is illustrated by the example pattern pairs below.

Table 3. Patterns with similar support but different significance.

Dataset	Example patterns	Significant	Support	Mean observed instance value (mean permuted instance value)
iSnap	*Block.grabbed→Block.snapped→IDE.changeCategory→Block.created→Block.grabbed*	Yes	0.70	5.60 (0.05)
	Block.snapped→Block.clickRun	No	0.70	5.67 (5.70)
LiRuYun	*View the course module→View the course module→View the course module→View the course module*	Yes	0.72	9.96 (4.73)
	View the course→View the course→View the course module	No	0.75	1.79 (3.77)

4.4 Example patterns with similar support but different significance

To illustrate the difference between support and statistical significance, we selected two pairs of patterns in which one pattern was significant and the other was removed despite similar support. More specifically, for each pattern we simultaneously report its support, the mean of the observed instance values, and the mean instance value under permutation (in parentheses). If the observed level is not elevated relative to the permutation reference, then even a relatively high support may still be driven primarily by incidental assembly of highly frequent event types. Conversely, if the observed level is substantially higher than the permutation reference, this suggests that the pattern remains statistically salient under the corresponding null hypothesis. We illustrate these points using examples from LiRuYun and iSnap below. In LiRuYun, the removed pattern *View the course → View the course → View the course module* had support of 0.75, but its observed instance mean was lower than its permuted baseline (1.79 vs. 3.77). By contrast, the significant pattern *View the course module →View the course module → View the course module → View the course module* had comparable support (0.72) but a much higher observed instance mean than its permuted baseline (9.96 vs. 4.73). In terms of learning behaviors, the removed pattern might reflect incidental navigation, such as briefly checking course pages before opening a module. In contrast, the significant pattern might be more consistent with repeated engagement with the same module during a learning episode.

A similar contrast appeared in the block-based programming data. The significant pattern *Block.grabbed → Block.snapped → IDE.changeCategory → Block.created → Block.grabbed* and the removed pattern *Block.snapped →Block.clickRun* had nearly identical support values, yet only the former showed a large gap between observed and permuted instance values (5.60 vs. 0.05), whereas the latter did not (5.67 vs. 5.70). The removed pattern might reflect a routine snap-and-run action that occurs frequently but not greater than expected frequency by chance. In contrast, the significant pattern might be more consistent with sustained constructive work, where learners repeatedly organized, modified, and extended blocks within the same problem-solving episode.

These examples show that patterns with similar support can differ substantially in their statistically significance and behavioral meaning. The proposed permutation-based screening assists in removing statistically weak patterns and distinguishing patterns that are more likely to reflect meaningful learning behaviors from those that may primarily reflect routine navigation or interaction.

5. LIMITATIONS AND FUTURE WORK

This study has several limitations. First, large candidate pattern sets and repeated permutations make the testing procedure resource-intensive. Future work should improve efficiency with parallelization and adaptive stopping.. Second, current permutation techniques assume exchangeability of inter-event gaps, which may not hold for autocorrelated or non-stationary learning behaviors. Third, results were based on a small number of datasets and contexts. Replication across more platforms and links to learning outcomes would strengthen generalizability and educational relevance.

ABSTRACT

To better understand the needs and support the development of computational thinking (CT) skills and persistence for young learners, we implement BarrelBots, a puzzle-based block coding activity in *Minecraft*, with middle school and high school learners. BarrelBots leverage an appealing and emotionally engaging agent that is controlled by a custom programming language. Learners solve a range of pre-designed puzzles of increasing difficulty. We present a comparison between two summer camps with identical BarrelBots curricula, a middle school and high school camp. To explore whether age impacts problem-solving behaviors, we ran a comparison of within-sequence Shannon entropy between the camps and found that younger students experienced more diverse states on a more difficult puzzle task. We then ran cSPADE, descriptive statistics, and hierarchical clustering of pairwise distances to understand how the problem-solving behaviors differed between the camps and between clusters within camps on the more challenging puzzle. The results demonstrated that high performing learners solved the task iteratively, behaviors like removing all blocks or rearranging blocks in subsequent attempts may indicate unproductive struggling or unproductive problem-solving behaviors, and younger students may benefit more from productive struggling while older learners should focus on fewer more deliberate attempts. The findings have implications for the development of wheel-spinning detectors and supports around persistence.

Keywords

Minecraft, computational thinking, sequential pattern mining, persistence, age-related differences

Computational thinking (CT) is fundamentally grounded in problem solving. Wing [27] characterizes CT as a way of approaching problems, system design, and human behavior through the application of core concepts from computer science. This framing positions CT as a cognitive process that extends beyond programming syntax, and encompasses how learners reason and approach complex tasks. Understanding CT problem solving therefore requires attention to how learners engage during CT activities. CT problem solving is inherently sequential and iterative, requiring learners to coordinate planning, execution, and evaluation across multiple attempts [23]. Productive persistence, sometimes framed as productive struggle, refers to sustained engagement that ultimately contributes to learning through iterative problem solving, strategy revision, and recovery from failure [16]. In contrast, non-productive persistence occurs when students continue working without making meaningful progress, often due to ineffective or unchanging strategies [14]. One well-studied manifestation of non-productive persistence is *wheel-spinning*, defined as situations in which learners persist for extended periods of time without achieving mastery or demonstrating durable learning [3, 14].

The importance of examining different learner characteristics and CT problem-solving skills has been emphasized in recent work. Research on the development of CT skills and learner characteristics like age, gender, prior experience, and other various learner characteristics are underexplored [2, 12, 25, 20]. Findings also suggest a need for deeper exploration into learners' CT problem-solving strategies. Common surface indicators such as time on task or number of attempts are often treated as straightforward proxies for engagement or effort. However, evidence suggests these measures can be unstable and difficult to interpret [17]. Therefore, relying on aggregate counts or durations alone risks obscuring the processes that produce CT learning. These concerns motivate analytic approaches that prioritize sequences of action. Examining the order and timing of behaviors provides greater leverage for distinguishing intentional revision from repetition, exploration from stagnation, and persistence from wheel-spinning. A method that has been used to understand persistence in education research is sequential pattern mining (SPM) [6]. SPM is a technique in educational data mining that discovers productive and un-

productive behavioral patterns in time-series data [15].

Thus, the aim of this study is to examine how age shapes both CT skill development and problem-solving behaviors associated with persistence among students engaged in *Minecraft* CT-focused, puzzle-based activities. Specifically, we investigate whether learners at different developmental stages (middle versus high school) demonstrate distinct problem-solving strategies when interacting with the same learning environment (BarrelBots). While prior work has used SPM to characterize problem-solving behaviors in game-based CT activities [26], little research has examined its use in *Minecraft* or whether the effectiveness of these behaviors varies by age. Addressing these gaps, our study explores age-related differences in puzzle-solving patterns, with a broader goal of informing the design of age-appropriate, just-in-time supports to promote persistence. Guided by these aims, we address the following research question: how do problem-solving behaviors, particularly those related to persistence, vary by participant age and computational thinking skill level during engagement with the same CT puzzle-based activity in *Minecraft*?

2. BARRELBOTS

Minecraft has become one of the most popular games in the world, with over 200 million monthly users, and 21.21% of daily user traffic originating from the U.S. [18]. Researchers have shown that even with little experience, learners master controls quickly and can effectively engage content when *Minecraft* is used in STEM learning environments [19]. Although some researchers caution about possible biases in *Minecraft* research [24], given the ubiquity of the game, ample opportunities to conduct research, and effectiveness to promote learning outcomes, *Minecraft* deserves attention for its potential in helping users in both formal and informal learning environments.

BarrelBots were modeled after the *Minecraft* barrel block with an approachable non-robotic appearance (see Figure 1). This is a step away from traditional computer science nomenclature like "agent" (programmable entities) and the association with robotics. They feature arrows on top indicating the direction that they are facing and will move, if instructed to go forward, in that direction (see Figure 1). Following suit with classic approaches to teaching sequential programming [21], BarrelBots provide a basic set of commands to the learner and three ways to move: move forward one block, rotate clockwise 90 degrees, and rotate counterclockwise 90 degrees. In addition, learners can unlock additional blocks including loops, conditionals, functions, and several specialized action blocks (e.g. to place a block in *Minecraft*, or "build").

Figure 1: BarrelBots have animated faces that indicate system status.

The BarrelBots activity contains researcher-designed puzzle modules that were previously tested with students from another pilot study. The puzzle modules are separated in "lanes". Each module is organized by a given CT construct and difficulty level. Participants are first introduced to three introductory puzzles that incorporate movement and loops (see Figure 2) , then two intermediate puzzles that incorporate conditionals, and lastly four difficult puzzles that incorporate sequencing and functions. Participants are given a set number of specific blocks per puzzle and are tasked with moving the BarrelBots from their starting position to the green block, representing the end state, while staying within the puzzle boundaries (see Figure 2).

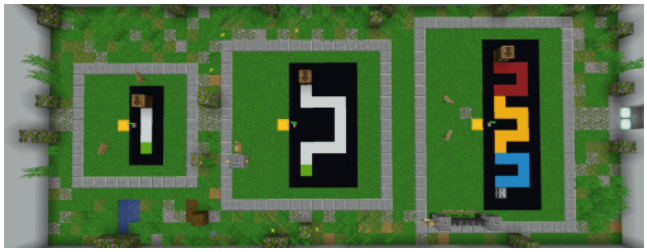

Figure 2: The first puzzle module series incorporating movement and loops.

3. METHODS

3.1 Participants

BarrelBots was deployed as part of a large week-long summer camp series in 2024 and 2025 that reaches over 100 middle and high school learners. Participants came from partner public schools that operate in some of the most under-served regions of a large midwestern city in the United States. Our study included two subsections (single week long classes) with a total of 18 learners in 2024 and 24 learners in 2025. The demographic breakdown of the 2024 camp is as follows: 72% African American, 17% White/Caucasian, 11% other ethnicity, 11% identified as female, and average age of 12.38. The demographic breakdown of the 2025 camp is as follows: 77% African American, 8% other ethnicity, 15% prefer not to answer, 23% identified as female, and average age of 13.45. Learners in both camps chose the BarrelBots activity out of several options. Many learners elected to participate in the BarrelBots camp but not all of them were able to be included. Most importantly, the majority of learners came from schools where there is limited computer science curriculum and many were beginner programmers.

3.2 Materials

Participants were all provided with a laptop, mouse, and an individual loaner (anonymous) account to play *Minecraft: Java Edition* on a server with the BarrelBots data pack described above. They used the same account for each session. The code blocks in BarrelBots are tracked every time players are finished editing their code and they are stored in a remote, secure database.

For pre- and post-tests, we used the 25-question competent Computational Thinking test (cCTt), a CT puzzle assessment developed by experts through use of focus groups and validated with substantial learner samples [7]. The measure

showed strong model fit for 6 latent factors representing CT concepts (e.g. while statements, loops) across all participants (ages 7 - 9; $\chi^2(260) = 551$, $p < .001$, CFI = .978, TLI = .974, RMSEA = .027, SRMR = .052). Overall internal reliability for the measure was high for the full sample (α = .85). The cCTt has also been shown to be valid and reliable with middle school students [8]. Although a measure with more complex items may be more useful for older students, we posit that the cCTt can be used with our participants. See Figure 3 for an example question from the measure.

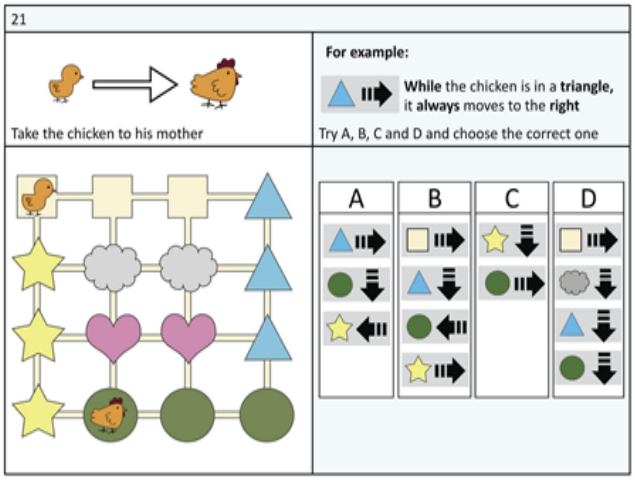

Figure 3: Example question from the cCTt.

3.3 Procedure

Both camps consisted of five days based in a classroom, with the first three being dedicated to BarrelBots activities. On the first day, campers tried activities related to all of the camps offered. They ranked their first and second choices. On the second day of camp, the participants that ranked the BarrelBots activity highest (or only) were selected to take part in the sessions. They were introduced to rules for the camp and for playing on the *Minecraft* server. The participants had 60 minutes to finish the puzzles in module 1 and create their own puzzle using loops. They then had 30 minutes to share the puzzle they created with their partners and the instructors. After a recess break, participants had additional time to work on module 2 (conditionals) and module 3 (sequencing and functions) puzzles and create their own puzzles for each module. The third day, participants had an hour to work on continuing puzzles from the previous day. After recess, they had time to continue the sequencing and function puzzles and had collaborative open build time if they finished early.

3.4 Data Analysis

We conducted SPM and descriptive statistics on participant game play behaviors to determine whether and how do the problem-solving behaviors differ by camp and CT competency. Borrowing from the methodology of Wang et al. [26], we used SPM to analyze the log data from two BarrelBots puzzles, an introductory and a more advanced puzzle, to mitigate bias. The introductory problem (see the middle puzzle in Figure 2) was intended to be solvable without prerequisite understanding of computing structures such as loops or conditionals. The more advanced puzzle was the final puzzle that was reached by participants in both camps. It contained an enemy bot that shot lasers that disabled BarrelBots and challenged participants to creatively figure out solutions to get around the obstacle using knowledge from previous modules.

To compare puzzle-solving strategies between the drastically different puzzles, we used BarrelBots inventory states [11] instead of the exact blocks used in the attempts (see Table 1 for definitions and examples of each inventory state).

Table 1: Definitions and examples for BarrelBots inventory states, [ ] = a player's code, f = forward block, r = right rotation block.

State	Definition	Example
Adding	An edit distance greater than 0 and the length of the subsequent inventory is greater than the length of the previous inventory.	[f] to [f,r,f]
Removing	An edit distance greater than 0 and the length of the subsequent inventory is less than the length of the previous inventory.	[f,r,f] to [f]
Rearranging	An edit distance greater than 0 and the length of the subsequent inventory is equal to the length of the previous inventory.	[f,r] to [r,f]
Not changing	An edit distance equal to 0 between subsequent and previous attempts.	[f] to [f]
Removing all	A subsequent inventory with a length of 0 and the length of the previous inventory is greater than the length of the subsequent inventory.	[f,r,f] to [ ]

We used the TraMineR package in R to compare and visualize the sequential player behavioral patterns from our participants [10]. To determine how the diversity of problem solving behaviors is related to the participant age we conducted a linear regression of within-sequence Shannon entropy on the camp type. Shannon entropy is a measure of diversity of states at a given position in the sequence [10], and is a methodology that has been used in social science research [4, 9]. To understand how the puzzle-solving patterns differ between groups we conducted cSPADE to compare the most frequent strategies used by participants within each camp. We specified a minimum support (minimum frequency that a sequence must occur in order to be considered) of .25 and a maximum gap (maximum time difference between to be considered consecutive elements) of 2 [15]. Lastly, to compare how puzzle-solving behaviors

differed within camps based on CT competency level, we used hierarchical clustering of pairwise distances between sequences with the TraMineR package to visualize player behavior patterns [26]. To calculate the pairwise distances between the sequences of inventory states for our participants we use the optimal matching method [1], a common sequence alignment algorithm that enables us to categorize patterns [1, 10]. We then used Ward's criterion to perform hierarchical clustering and group similar sequences [22]. To determine the number of clusters that should be used for each camp, we used the dendrograms for each dataset to visually identify the approximate number of groupings.

4. RESULTS

4.1 Pattern Differences Between Camp

A linear regression for the camp type on the Shannon entropy values of the player sequences on the introductory puzzle was insignificant, $F(1,53) = .89$, $p = .35$. The linear regression for the camp type on the Shannon entropy values of the player sequences on the more challenging puzzle, however, was significant, $F(1,34) = 7.40$, $p = .01$, $R^2 = .18$, adjusted $R^2 = .15$. Middle school students had significantly more diversity of states in their sequences, $t(34) = 2.72$, $p = .01$. Since the main construct of interest of this study is persistence, which is typically exhibited on more advanced tasks [14], and we did not find significant differences in state diversity on the introductory puzzle, follow-up analysis was only ran on the more challenging puzzle.

4.2 cSPADE Patterns Between Camps

The results of cSPADE for the frequent patterns on the more advanced puzzle showed that students in both camps used similar puzzle-solving behaviors. The support, percentage of learners in the group that used the sequence of inventory states, for patterns in the middle school camp was typically higher than the support for the same patterns found for the high school camp. High school learners, however, had higher support for iterative problem-solving patterns (Add $\rightarrow$ Add and Add $\rightarrow$ Add $\rightarrow$ Add). One behavior that was found with the middle school students that was not present with the high school students was Remove All.

4.3 Cluster Analysis of Puzzle-Solving Behaviors Within Camps

Following the methodology of Wang et al. [26], since we are primarily interested in developing personalized supports for persistence early in the puzzle-solving task, we truncated each participants' inventory sequences to the first 10 states (half of the mean number of attempts per participant used on the task). From visual inspections of the dendrograms that visualize the hierarchical relationships of the clusters, we concluded that three clusters were optimal for both camps.

For the middle school camp, participants who scored the highest on the cCTt post-test most frequently tackled the problem iteratively by focusing their early attempts on adding new blocks. Players in this cluster later removed blocks then added new ones. Participants in the lowest scoring clusters frequently added blocks then removed all of them perhaps when their initial strategy did not work.

For the high school camp, participants who scored the highest on the cCTt post-test most frequently tackled the problem iteratively by focusing their early attempts on adding new blocks. The players in the lowest scoring cluster added blocks but unlike other clusters rearranged them in multiple subsequent attempts.

4.4 Number of attempts

On the more challenging puzzle, the middle school learners used almost double the amount of attempts than the high school learners. On average, the younger students took 25.36 attempts (SD = 16.19), ranging from 3 to 59, when working on the challenging puzzle task. The participants in the highest scoring middle school camp cluster for the cCTt post-test used the most attempts, $M = 31.80$, SD = 21.43, ranging from 15 to 59 attempts. The participants in lowest scoring clusters used about the same amount of attempts. On average, the learners in the second lowest scoring cluster used 21 attempts (SD = 15.35) ranging from 3 to 37, and the lowest scoring cluster used 23.33 attempts (SD = 5.51) ranging from 18 to 29. These findings suggest that for our middle school participants that more attempts may be linked to higher CT knowledge.

The high school learners used less attempts than the middle school learners, $M = 14.56$, SD = 10.83, ranging from 4 to 50. Unlike the middle school camp, the highest scoring cluster for the cCTt post-test in the high school camp used the least attempts, $M = 8.88$, SD = 3.72, ranging from 4 to 16. The second highest scoring cluster used the second least amount of attempts, $M = 13.67$, SD = 6.92, ranging from 8 to 27. The lowest scoring cluster used the most attempts, $M = 27.25$, SD = 15.87, ranging from 16 to 50. These findings suggest that for our high school participants that less attempts use may be linked to higher CT knowledge.

5. DISCUSSION

Insights from the game play behaviors of low- and high-performing students can assist the development of wheel-spinning detectors and supports around persistence for students from similar backgrounds [28]. The results from SPM demonstrate that high performing learners at both camps, participants that scored the highest on the cCTt post-test, most frequently used strategies that align with characteristics of productive struggle and deliberate problem solving such as iteratively adding blocks to their BarrelBots inventory in subsequent steps [16], strategy revision [16], and increased time intervals between behaviors [5]. From the between-camp cSPADE analysis, despite the middle school participants having relatively higher supports for their frequent puzzle-solving patterns, they had lower supports for iterative puzzle solving patterns (*e.g.,* Add $\rightarrow$ Add and Add $\rightarrow$ Add $\rightarrow$ Add). The within camp clustering also found that the high performing learners at both camps most frequently used strategies that incrementally added blocks to their BarrelBots inventory in subsequent steps. These finding align with CT practices like being incremental and iterative [23]. The highest performing middle school cluster demonstrated in their most frequent problem-solving pattern that after iteratively adding blocks in early attempts they removed some blocks and added more, which may be an indication of a strategy revision.

The descriptive statistics for the average number of attempts and informal analysis of average player latency between subsequent inventory states after removing outliers for each cluster shows that middle school learners benefit from using more inventory states with less time in between attempts, while high performing clusters in the high school group used less states with more time in between attempts. Middle school participants in the highest performing cluster spent less time between attempts compared to the lowest scoring middle school cluster, 57.28 seconds versus 96.85. The high school learners in the highest performing cluster spent more time between attempts and used fewer attempts compared to the high school learners in the other clusters. Together with the SPM results, the relatively large amount of time between attempts and fewer attempts could indicate that high-performing high school participants were more deliberate with their attempts.

The low performing learners at both camps, participants that scored the lowest on the cCTt post-test, most frequently used problem-solving patterns that align with characteristics of wheel-spinning [16]. The presence of removing all blocks may be an indication of wheel-spinning. The participants from the middle school camp in the cSPADE analysis and lowest performing clusters from that camp both had removing all blocks as a state in their most frequent patterns. *Middle school learners also used almost double the amount of attempts compared to participants in the high school camp.* Together these findings indicate that the low-performing middle school learners may have experienced wheel-spinning, they persisted during the task but were more prone to giving up on their ideas causing them to spend extended time on the puzzle without meaningful progress. Although remove all was not a state present in the most frequent patterns for the high school learners, rearranging blocks in subsequent attempts was only used by the lowest-scoring cluster and could be indicative of non-productive game play behaviors. High school participants in the lowest performing cluster used more attempts and seemingly more non-deliberate actions compared to the highest scoring cluster when solving the difficult puzzle.

5.1 Limitations and Future Work

A limitation for our study is our relatively small sample size and choice to conduct our analyses on camps that took place in subsequent years, which could potentially alter our results. For our analyses we also solely rely on log data. Triangulation with other data sources like video and audio of students working on the task could enable us to find more nuanced results and could be a beneficial direction for the field.

Prior work has demonstrated the potential for large language models (LLMs) to provide meaningful, adaptive feedback to students within *Minecraft*-based learning environments [13]. Building on this foundation, our future work will leverage the indicators of persistence identified in this study, along with the strategies students employ during wheel-spinning, to inform the design of system prompts that enable LLMs to deliver targeted, conversational feedback. Overall, we are optimistic that these future supports, grounded by the findings from this study, will enhance student persistence, reduce wheel-spinning, and improve learning outcomes for students.

ABSTRACT

Contrastive learning is a machine learning technique that optimizes the embedding space by pulling positive pairs closer and pushing negative pairs farther. Recently, knowledge tracing (KT) models have adopted contrastive learning to learn the representation of students' interaction sequences. Therefore, augmentation methods should preserve students' knowledge states when generating positive pairs and distort them when generating negative pairs. Which means that augmentation methods should take into account the pedagogical semantics beneath students' interaction sequences. However, random augmentations may ignore the educational context and consequently alter the underlying knowledge representations. To address this issue, we propose a graph-based augmentation method that leverages an interaction graph, where each node denotes a skill-response pair and each edge captures the conditional transition probability between interactions. The interaction graph is constructed using transition probabilities predicted by a trained DKT model for the next interaction. Each augmentation method generates learning paths by following transition probabilities in the interaction graph, enabling the construction of structurally plausible sequences. This design preserves pedagogically meaningful transitions within augmented sequences. Furthermore, we explored whether pairs generated by random augmentation methods and our graph-based augmentation methods function as positive or negative pairs. Our results show that graph-based augmentation can effectively generate sufficient and meaningful pairs. However, we find that knowledge state preservation differs between the human perspective and the model's perspective. Future work is needed to further explore and understand this difference.

1. INTRODUCTION

In recent years, Knowledge Tracing (KT) has been actively studied as a fundamental task in Intelligent Tutoring Systems (ITS). In order to capture the current knowledge state within an ITS, KT estimates the probability of a correct response by taking the student's historical learning path and a target skill as inputs. The estimated knowledge state supports personalized instruction and adaptive learning systems.

To better capture the dynamics of knowledge states, various deep learning approaches have been proposed for KT. Among these, contrastive learning has gained attention as a representation learning framework. It trains models by pulling together semantically similar (positive) pairs while pushing apart semantically dissimilar (negative) pairs. Several studies have adopted contrastive learning in KT by applying data augmentation to construct these pairs from student interaction sequences. For instance, CL4KT[3] was proposed to improve representation learning under sparse interaction data by applying random augmentations to construct positive and negative pairs, encouraging semantically similar learning histories to have closer representations through a contrastive objective. This approach demonstrated the effectiveness of contrastive learning in enhancing knowledge state representations and improving KT performance.

However, in contrastive learning for KT, it remains unclear whether commonly used augmentation methods function as valid positive or negative pairs. Recent work such as QCKT[8] has highlighted that the criteria for selecting positive and negative samples remain insufficiently defined. In KT, semantic similarity reflects the consistency of the students' latent knowledge state. Therefore, in this work, positive pairs are defined as sequence pairs that preserve the students' knowledge state, and negative pairs as those that distort it. Based on this definition, we investigate whether each augmentation method acts as a positive or negative pair, based on its effect on the students' knowledge state.

Despite these successes, we identify several limitations of existing augmentation approaches. First, current models fo-

cus on sequence-level augmentations.[9, 1] However, these methods do not fully capture the structured learning path that emerges from the underlying connections between skills. Second, random augmentations may overlook the educational context of the data and risk distorting the underlying logic of knowledge acquisition.[5] For example, if a prerequisite question is randomly replaced or removed, it creates an invalid sequence that contradicts the actual logic of a students' knowledge acquisition. Such augmentations may lead to sub-optimal contrastive objectives by providing the model with semantically invalid positive pairs.

To address this limitation, we propose graph-based augmentation methods that leverage an interaction graph over student interactions. Rather than applying random perturbations, our approach generates augmented sequences by following transition-weighted paths in the graph, enabling structure-aware augmentations that reflect meaningful pedagogical transitions.

To systematically analyze the role of augmentation methods in contrastive learning for KT, we evaluate both existing random augmentations and the proposed graph-based augmentations in terms of their suitability as positive or negative pairs. Specifically, we assess their suitability based on AUC gain, where higher performance indicates better alignment with the assigned role.

The following research questions are investigated in this study:
RQ1. How do random augmentation methods behave when assigned as positive or negative pairs in contrastive learning for KT?
RQ2. How do graph-based augmentation methods behave when assigned as positive or negative pairs in contrastive learning for KT?
RQ3. How does the performance of the full random augmentation setting compare to that of the full graph-based augmentation setting?

2. METHOD

2.1 Graph-based Augmentation

2.1.1 Definition of interaction graph

Graph-based Knowledge Tracing (GKT) [6] has attempted to capture structured skill relationships and educational context by modeling relationships between skills as graph structures. However, existing studies focus primarily on skill-to-skill correlations.[2, 4, 10] Consequently, there is still a lack of research that utilizes interaction nodes to fully capture the directionality of a students' knowledge state. To address this gap, we employed DKT graph. Given $|S|$ skills, the graph contains $N = 2|S|$ interaction nodes, and each interaction (s, r) with $r \in \{0, 1\}$ is mapped to a node index $v = s+|S|\cdot r$. We define a weighted interaction graph $G = (V, E)$ and its corresponding adjacency matrix $A_{ij} \in \mathbb{R}^{N\times N}$. To capture various pedagogical aspects, we construct an adjacency matrix based on a DKT graph. The DKT graph is a model-based interaction graph constructed from the conditional prediction probabilities of a trained DKT model [7]. Given a student interaction (s_t, r_t) at time step t, we estimate the probability that a student answers a target skill s_{t+1} correctly at the next step. Specifically, the trained DKT model provides

$$p_1 = \Pr(r_{t+1} = 1 \mid s_t, r_t, s_{t+1})$$

which represents the likelihood of correct response on skill s_{t+1} given interaction (s_t, r_t). The probability of an incorrect response is defined as

$$p_0 = \Pr(r_{t+1} = 0 \mid s_t, r_t, s_{t+1}) = 1 - p_1.$$

Based on these predictions, response r_t is determined as 1 if $p_1 \geq p_0$ and 0 otherwise. To ensure reliable transitions, a threshold τ is defined and only transitions satisfying $\Delta = |p_1 - p_0| > \tau$ are retained, with τ set to 0.5 in practice to preserve only transitions with sufficiently meaningful differences. To determine the edge weights, we define $w = \max(p_1, p_0)$, selecting the higher probability between a correct and an incorrect response at the next step. We then retain the top-k transitions with highest w values for each node, defining the weighted adjacency matrix as $A_{ij} = w$.

2.1.2 Graph-based augmentation method

Using the DKT graph defined above, we propose six graph-based augmentation methods. All augmentations leverage the weighted adjacency matrix A to ensure that generated sequences reflect meaningful transitions between interaction nodes.

Graph-based Masking Masking candidates are restricted to interactions that have at least one neighbor within the same sequence with a transition weight above threshold τ. Only these eligible interactions are subject to masking, ensuring that masked positions remain inferable from their structural context, thereby preventing excessive distortion of the students' knowledge state.

Graph-based Crop Transition weights between consecutive interaction pairs are computed using the adjacency matrix A, reflecting how strongly each pair of interactions is connected. Based on these weights, the position with the weakest connection (i.e., the minimum transition weight) is identified and used as the boundary for cropping. The subsequence closer to the target crop length is then retained, ensuring that the remaining segment consists of strongly connected interactions, thereby preserving a consistent and meaningful learning context.

Graph-based Extension For each interaction (s, r), a weighted candidate set is constructed by sampling neighboring interactions (s', r') from the row-normalized adjacency matrix A, excluding same-skill nodes. Using this candidate set, two augmented views $\mathbf{x}^{+1}$ and $\mathbf{x}^{+2}$ are generated via prior and posterior extension, respectively. In prior extension, (s', r') is appended before the head of the sequence; in posterior extension, it is appended after the tail. If the sequence exceeds the maximum length, the opposite end is truncated accordingly.

Graph-based Branching Path Sequence pairs are constructed to share the same initial interactions and diverge from a branching point. From this point, the remaining interactions are generated by traversing the graph, sampling from the top-k neighbors based on transition strength and proximity to a target endpoint. The final interaction is constrained to match the original skill but with a flipped response, ensuring

divergence in the terminal knowledge state while preserving overall structural similarity.

Graph-based Path Substitution The first and last interactions of a sequence are preserved, while an intermediate segment is replaced with an alternative path generated from the interaction graph. Specifically, the intermediate segment is selected and replaced by traversing the adjacency matrix A to construct a new path between the two fixed anchor points. During this process, interactions from the original segment are penalized to encourage the generation of diverse alternative paths, while the initial and final interactions remain consistent.

2.2 Experiment Settings

2.2.1 Benchmark Datasets

To evaluate the performance of the proposed method, we utilized the ASSISTment 2009 dataset. To ensure data integrity, we applied several preprocessing steps before model training. Specifically, users with fewer than five interactions were excluded, and interactions without explicit concept tags were removed to maintain clear concept mapping.

ASSISTments (2009). . These datasets were obtained from an online mathematics tutoring platform. Specifically, we used the ASSISTment 2009-2010 "Skill Builder"set version.

Table 1: Statistics of the Datasets

Dataset	Users	Items	Skills	Interactions	Avg. Seq Length
ASSISTments 09	3,695	17,728	112	282,071	76.34

2.2.2 Experimental design

To investigate whether each augmentation method is more suitable as a positive or negative pair, each augmentation is evaluated under two distinct roles within the InfoNCE loss. When evaluated as a positive, the augmentation is applied to both views $\mathbf{x}^{+1}$ and $\mathbf{x}^{+2}$ with masking. When evaluated as a negative, the augmentation is used to generate the hard negative z_k, while both positive views consist of masking only. We use masking alone as the base positive, as it is considered the most conservative augmentation that is least likely to distort the students' knowledge state. We evaluated two augmentation methods: random augmentations adopted from CL4KT [3], including crop, replace, and permute; and our proposed graph-based augmentations, including prior extension, posterior extension, graph-based crop, graph-based branching path, and path substitution. Each augmentation is tested in both roles, and performance is compared to determine whether it is more appropriate as a positive or negative pair. We also include two additional baselines: No CL, where the model is trained without any contrastive objective, and Full, which represents the best configuration for each augmentation type.

2.2.3 Implementation details

The embedding dimension and hidden dimension were fixed to $d = 64$ for all experiments. Student interaction sequences were sorted chronologically for each user. To standardize sequence lengths, we retained up to the most recent 50 interactions per student; longer sequences were truncated, while shorter ones were zero-padded. All models were evaluated using 5-fold cross-validation, with the Area Under the ROC Curve (AUC) serving as the primary metric. All experiments share masking probability of $r_{\text{mask}} = 0.1$, and the target augmentation method in each condition is applied with a transformation ratio of 0.2. When evaluated as a negative, r_{neg} is set to 1.0; otherwise, it is set to 0. The Full configuration applies both $r_{\text{mask}} = 0.1$ and $r_{\text{crop}} = 0.2$ as positive views, with $r_{\text{neg}} = 1.0$ for hard negative generation. All models were trained using the Adam optimizer with a learning rate of 0.001 and a batch size of 64. We applied a learning rate scheduler that decayed the learning rate by a factor of 0.5 when the validation AUC did not improve for five consecutive epochs, and early stopping was applied if no improvement was observed for 5 consecutive epochs.

3. RESULTS

3.1 RQ 1. Effect of Random Augmentation on Positive and Negative Pairs

Table 2 presents the performance of random augmentation methods when used as either positive or negative pairs. As shown in the table, random augmentations generally achieve higher performance when used as positive pairs than as negative pairs. In particular, replace shows a noticeable performance drop when used as a negative pair, while crop and permute also exhibit a moderate gap. Based on these results, crop, replace, and permute tend to be more suitable when used as positive pairs. From a knowledge state perspective, this provides partial evidence that these random augmentations may better maintain consistency with the original learning sequence when used as positive pairs. These findings highlight that the behavior of random augmentations depends on how they are incorporated within the contrastive learning framework, and that their role assignment can influence their effectiveness.

Table 2: Effect of Random Augmentation on Positive and Negative Pairs

	Positive	Hard negative	Δ
Crop	0.74135	0.73906	+0.00229
Replace	0.73179	0.71676	+0.01503
Permute	0.72977	0.72717	+0.0026
Full random	0.72487		

3.2 RQ 2. Effect of Graph-based Augmentation on Positive and Negative Pairs

Table 3 shows the performance of each graph-based augmentation as a positive or negative pair. Overall, graph crop, branching path, and path substitution tend to perform better as positive pairs, suggesting that these methods are more aligned with the role of positive pairs from a knowledge state perspective. In contrast, prior and posterior extension show slightly better performance as negative pairs, although the differences compared to their positive counterparts are not substantial. For augmentation methods that do not exhibit a clear performance gap between roles, it is less straightforward to determine their appropriate assignment within the

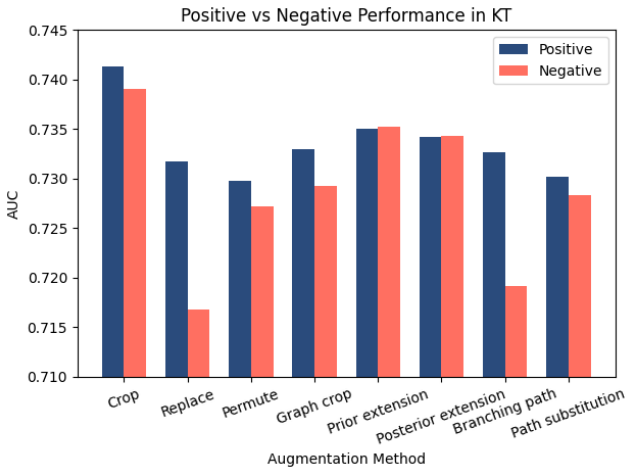

Figure 1: Comparison of AUC performance for each augmentation method under positive and negative pair assignments in knowledge tracing.

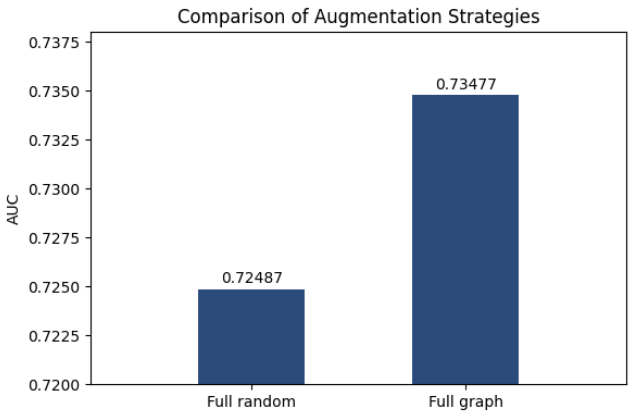

Figure 2: Performance Comparison between Full Random and Graph-based Augmentation Settings

contrastive framework. These methods can be interpreted as producing pairs with only minor semantic differences, rather than clearly positive or strongly negative ones. Additionally, in the case of branching path, although it was originally designed as a hard negative by transitioning from the original sequence to a node with a different response, it shows one of the most pronounced performance differences when used as a positive pair. This observation suggests that its behavior is not fully aligned with its intended role, requires further discussion regarding its underlying cause. The results of RQ1 and RQ2 are further illustrated in Figure 1, where the differences between augmentation methods across roles can be clearly compared.

Table 3: Effect of Graph-based Augmentation on Positive and Negative Pairs

	Positive	Hard negative	Δ
Graph crop	0.73299	0.72922	+0.00377
Prior ext	0.73502	0.73526	−0.00024
Posterior ext	0.73418	0.73428	−0.00010
Branching path	0.73271	0.71912	+0.01359
Path subst	0.73020	0.72834	+0.00186
Full graph		0.73477	

3.3 RQ 3. Comparison of Full Random and Full Graph-based Augmentation

We evaluate the Full configuration for both random and graph-based augmentation settings. In the random setting, all augmentation strategies—masking, crop, permute, and replace—are employed to construct positive views, while negative samples are drawn from the interaction histories of other students within the same mini-batch. For the graph-based setting, the Full configuration is constructed based on the observed performance of each method, where graph mask, graph crop, branching path, and path substitution are assigned as positive pairs, and prior and posterior extension are used as hard negatives. As shown in Figure 2, the graph-based Full configuration achieves the best overall performance (AUC = 0.73477), outperforming the random augmentation-based Full configuration (AUC = 0.72487). This comparison highlights the effectiveness of graph-based augmentation in the full setting. However, it is also observed that the AUC obtained from the Full configurations is lower than the best performance achieved by individual augmentation methods (e.g., random crop and prior extension). This suggests that simply combining multiple augmentation strategies does not necessarily lead to further performance gains, and that further consideration is needed on how to effectively combine them.

4. CONCLUSION

In this work, we investigated graph-based augmentations from the perspective of knowledge state preservation and distortion, and compared them with commonly used random augmentations. To construct structure-aware augmentations, we build an interaction graph using a trained DKT model, where edges are defined by conditional prediction probabilities. This results in a weighted graph that reflects meaningful learning paths, based on which we generate augmented sequences along valid transitions. To evaluate their effectiveness, we analyze how each augmentation method contributes to contrastive learning when assigned as either a positive or negative pair, by examining performance differences across roles. The results show that random augmentations are generally more suitable for positive pairs, while in the graph-based setting, most augmentation methods, except for extension-based approaches, show similar tendencies. In particular, prior and posterior extension exhibit only marginal differences between roles, indicating low sensitivity to role assignment. In contrast, the proposed branching path method, originally designed as a hard negative, demonstrates a clear AUC gain when used as a positive pair. This suggests that its empirical behavior does not fully align with its intended role. Additionally, in this study, the semantic role of each augmentation method was discussed only through downstream AUC performance, which provides an indirect perspective on whether an augmented learning path is truly semantically equivalent to the original sequence. Future work should therefore develop quantitative measures for

semantic equivalence and revisit whether knowledge state preservation and distortion from a human perspective are aligned with those learned by contrastive learning models. Furthermore, it remains unclear how augmentation methods with minor performance differences across roles should be incorporated into the contrastive learning framework. These methods may instead be better suited for data augmentation or regularization, and we suggest this as a direction for future work.

Predicting Disagreement with Human Raters in LLM-as-a-Judge Difficulty Assessment without Using Generation-Time Probability Signals

Yo Ehara
Tokyo Gakugei University
ehara@u-gakugei.ac.jp

ABSTRACT

Automatic generation of educational materials using large language models (LLMs) is becoming increasingly common, but assigning difficulty levels to such materials still requires substantial human effort. LLM-as-a-Judge has therefore attracted attention, yet disagreement with human raters remains a major challenge. We propose a method for predicting which LLM-generated difficulty ratings are likely to disagree with human raters, so that such cases can be sent for re-rating. Unlike prior approaches, our method does not rely on generation-time probability signals, which must be collected during rating generation and are often difficult to compare across LLMs. Instead, exploiting the fact that difficulty is an ordinal scale, we use a separate embedding space, such as ModernBERT, and identify disagreement candidates based on the geometric consistency of the rating set. Experiments on English CEFR-based sentence difficulty assessment with GPT-OSS-120B and Qwen3-235B-A22B showed that the proposed method achieved higher AUC for predicting disagreement with human raters than probability-based baselines.

Keywords

Disagreement, Difficulty Annotation, Large Language Models

1. INTRODUCTION

In recent years, improvements in the performance of large language models (LLMs) and the development of supporting infrastructure have made it increasingly practical to automatically generate educational content such as practice questions, example sentences, and explanations for learners. As a result, the potential for educational applications has been expanding rapidly. At the same time, whether instructional materials are at an *appropriate difficulty level* for learners is directly related to both learning effectiveness and fairness. Difficulty assessment is therefore a foundational task in the deployment of generated educational materials. However, manual difficulty rating requires expertise and time, and thus easily becomes a bottleneck in large-scale operation.

To address this human-evaluation cost, *LLM-as-a-Judge*, in which an LLM also serves as an evaluator, has attracted increasing attention [16]. LLM-as-a-Judge can reduce the temporal and financial costs of evaluation by lowering the burden on teachers and other human evaluators who would otherwise need to assess large numbers of examples and instructional materials for difficulty and related properties. At the same time, however, reliability, robustness, and alignment with human judgments have repeatedly been identified as major challenges [2, 13, 3]. Therefore, in practical use, it is important not to accept LLM ratings as they are, but instead to efficiently identify cases that are likely to disagree with human judgments, that is, candidate cases of inter-rater disagreement.

One promising cue for identifying such disagreement candidates is to use generation probabilities output by the LLM at rating time, such as log-likelihoods or probability distributions. However, this approach has practical limitations: such signals are available only at generation time. Thus, if they are not collected, they cannot be recovered later. In addition, because generation probabilities differ across models, they are difficult to compare across LLMs.

Building on this motivation, this study extends the framework proposed in [6] and proposes a method for predicting, without using LLM probability signals, which difficulty ratings produced by LLM-as-a-Judge are likely to disagree with human raters. The key idea of this study is that difficulty is an ordinal scale. In language difficulty estimation and readability assessment, deep representations such as BERT embeddings have been shown to be effective [4], and it is also well known that embedding spaces exhibit geometric structure, including directionality and anisotropy [9]. Based on this observation, we prepare, independently of the LLM used as the rater, a separate embedding space such as that of ModernBERT [14], and detect as disagreement candidates those ratings that are geometrically inconsistent with the ordinal difficulty structure, that is, with the alignment and consistency of the rating set as a whole.

This approach has two major practical advantages. First, because it does not depend on probability outputs, it can be applied even when such signals were not collected at the time the LLM-as-a-Judge generated its ratings. Second, unlike

https://doi.org/10.5281/zenodo.21039851

probability outputs, the quantities used by our method are geometric, which makes them comparable across difficulty labels assigned by different LLMs on the same dataset. Furthermore, the model used for the embedding space is much smaller than the LLM used for rating, with fewer than 1 billion parameters.

In our experiments, we consider an English CEFR-based difficulty assessment task, which provides internationally shared and rigorous difficulty criteria, and predict disagreement with human ratings for sentence difficulty labels produced by the open-weight LLMs gpt-oss-120b [12] and Qwen3-235B-A22B [15]. The results show that the proposed method predicts disagreement with higher AUC than methods based on LLM probability signals, demonstrating its effectiveness as a probability-free and interpretable method for prioritizing cases for re-rating.

2. RELATED WORK

Methods for LLM-as-a-Judge, which assess the extent to which LLM evaluations are correct, have often relied on LLM probability signals. For example, LLM-Rubric presents a framework that calibrates human ratings by using the probability distribution over rubric-based questions as input [10]. However, the use of probability signals still poses practical challenges: (i) they must be obtained at the same time as the rating is generated, and are therefore affected by logging availability and API constraints; and (ii) probability scales and calibration differ across models, making comparison and interpretation difficult. In addition, as a black-box approach to uncertainty estimation that does not rely on probability distributions, previous work has proposed detecting anomalies from the self-consistency of sampled outputs (e.g., SelfCheckGPT) [11], although such methods may require temperature adjustment or other sampling controls.

In language learning research, although assigning difficulty levels based on a common framework is important, it has been noted that constructing sufficiently large, high-quality annotated datasets is itself difficult. For example, a study that constructed a CEFR-based sentence difficulty corpus (CEFR-SP) and demonstrated sentence difficulty estimation using BERT-based models was motivated by this challenge [1].

3. PROPOSED METHOD

The proposed method extends the framework proposed in [6]. We first provide an intuitive explanation of the method using Fig. 1. First, we prepare an embedding vector space that is *completely separate* from the one used for difficulty labeling. For example, we assume a well-known encoder such as BERT [5] or ModernBERT [14], and all embedding vectors are assumed to be normalized to unit length. The main idea of [6] is that, given such an embedding space together with a set of difficulty labels assigned by an LLM, one can uniquely compute a vector that represents the degree of geometric consistency between the embedding space and the difficulty labeling.

Although [6] evaluates only the consistency of the difficulty labeling as a whole, it is also possible to compute the degree of consistency between the embedding space and each individual difficulty label. The proposed method uses this

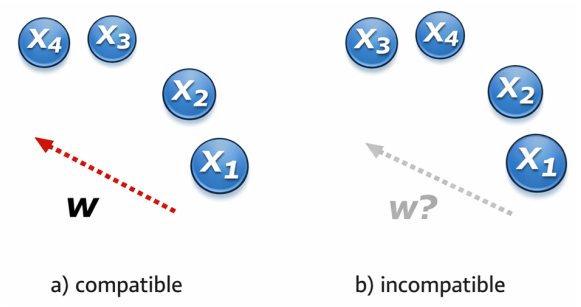

Figure 1: Figure reproduced from [6] with their permission. In (a), let $\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3$, and $\mathbf{x}_4$ denote two-dimensional word or sentence embeddings. We write $\mathbf{x}_1 \prec \mathbf{x}_2 \prec \mathbf{x}_3 \prec \mathbf{x}_4$ to indicate that $\mathbf{x}_1$ is annotated as easier than $\mathbf{x}_2$, $\mathbf{x}_2$ as easier than $\mathbf{x}_3$, and so on. In this case, if the points are ordered along the direction of $\mathbf{w}$ in the two-dimensional space, the resulting order matches the annotation. In contrast, in example (b), no such direction exists. In practice, most datasets and embedding spaces are closer to the situation in (b), but the degree of alignment is defined by how well one can find a direction that satisfies the ordering in (a) with as few constraint violations as possible. In addition, for a given instance, the degree to which the average of the difference vectors between that instance and all other instances is aligned with $\mathbf{w}$ is defined as the alignment score of that instance.

property: difficulty labels with low consistency with the embedding space are treated as candidates for low inter-rater agreement, that is, cases likely to show disagreement when another rater is introduced. We now describe their method in more detail. Consider N embedding vectors $\{\mathbf{x}_1, \ldots, \mathbf{x}_N\}$, where each $\mathbf{x}_i$ is a D-dimensional vector. We assume that all embedding vectors are normalized, that is, $||\mathbf{x}_i|| = 1$, where $||\mathbf{x}_i||$ denotes the Euclidean norm of the vector. Let $\mathbf{w} \in \mathbb{R}^D$ be a D-dimensional vector representing a direction in the embedding space. They convert difficulty labels into pairwise constraints between two instances. They denote by $\mathbf{x}_i$ the vector judged to be *easier*, and by $\mathbf{x}_j$ the vector judged to be *more difficult*. Then, the condition that instances are aligned in the embedding space in order of difficulty when viewed along the direction $\mathbf{w}$ can be written as $\mathbf{w}^\top (\mathbf{x}_i - \mathbf{x}_j) < 0$. To transform the inequality constraints into equality constraints, we introduce variables that represent the degree to which each constraint is satisfied (slack variables), and write $\mathbf{w}^\top (\mathbf{x}_{i_k} - \mathbf{x}_{j_k}) + \xi_k = 0$. Here, k is an index over constraints.

At this point, by considering that $\mathbf{w}$ is a direction vector, that is, $||\mathbf{w}||^2 = 1$, and searching for the direction $\mathbf{w}$ that maximizes the sum of all ξ_k values (the degrees to which the constraints are satisfied), we obtain the following mathematical optimization problem. Here, although originally $T = 0$, if we relax it to $T = -\infty$, the optimal $\mathbf{w}$ can be computed in closed form simply as the mean vector of the differences between labeled pairs.

$$\max_{\mathbf{w},\xi} \sum_{k=1}^{K} \xi_k, \tag{1}$$

$$\text{s.t. } \forall k, \quad \mathbf{w}^\top (\mathbf{x}_{i_k} - \mathbf{x}_{j_k}) + \xi_k = 0, \quad \xi_k \geq T, \; ||\mathbf{w}||^2 = 1 \tag{2}$$

The solution to (2) is given by $\mathbf{w} \propto -\sum_{k=1}^{K}(\mathbf{x}_{i_k} - \mathbf{x}_{j_k})$. Let $\bar{\mathbf{x}}_i$ denote the mean vector of level i, and similarly for level j, and let N_i and N_j denote the numbers of instances at levels i and j, respectively. Then, $\mathbf{w}$ can be written as $\mathbf{w} \propto -(N_i\bar{\mathbf{x}}_i - N_j\bar{\mathbf{x}}_j)$. We refer to the method using this direction as "exactw." Although the exact solution can be written in this form, in practice, when the numbers of instances at some levels are small as a result of LLM-based difficulty labeling, computing $\mathbf{w}$ exactly may lead to a biased direction vector. Since $\mathbf{w}$ only needs to be a direction vector, we also propose a simpler method, "most2," in which $\mathbf{w}$ is defined as the difference between the mean vectors of the two labels that were assigned most frequently by the LLM.

Once the direction $\mathbf{w}$ has been obtained, the values of ξ_k can be computed accordingly. Then, by summing the ξ_k values over all constraints involving item i, we can compute the degree of consistency for item i.

4. EXPERIMENTAL SETUP

For the evaluation in this study, a dataset with rigorously obtained human ratings is desirable, and it is also important that the dataset include difficulty labels provided by multiple human raters. For this reason, we used the CEFR-SP dataset [1]. In this dataset, the difficulty of English sentences is rated by two expert annotators on a six-level scale, A1, A2, B1, B2, C1, and C2, based on the Common European Framework of Reference for Languages (CEFR), which is a standard and widely used framework for English proficiency in English language education.

Next, in this study, we needed baseline models from which confidence scores (token generation probabilities) could be obtained. For this purpose, we used GPT-OSS-120B and Qwen3-235B-A22B (hereafter, Qwen3) for labeling, as they were among the largest models that could be run locally on a single GPU as of February 2026.

The input consisted of 10,004 English sentences. The label distribution produced by GPT-OSS-120B was A1: 500, A2: 3,345, B1: 2,899, B2: 3,230, C1: 29, and C2: 1. For Qwen3, the distribution was A1: 635, A2: 1,626, B1: 4,014, B2: 3,293, and C1: 436.

Performance in disagreement detection was evaluated using ROC-AUC, PR-AUC, and Precision@20. ROC-AUC is the area under the ROC curve obtained by thresholding the decision function and plotting the resulting pairs of true positive rate and false positive rate. PR-AUC is the area under the precision–recall curve obtained by similarly sweeping the threshold. Precision@20 denotes the precision when the top 20 instances ranked in descending order of $s(i)$ are regarded as candidates for re-evaluation. For all metrics, sentences for which the label assigned by the LLM differed from that of human Rater A or B were treated as positive instances.

4.1 Difficulty Labeling by LLMs

For the logprob-based baseline, we used the token log-probability of the label sequence output by GPT-OSS-120B or Qwen3 (logprob_label) as the confidence score for disagreement detection.

The prompt included the CEFR criteria descriptions in the user input, and in practice we used the following System/User strings exactly as written:

> System: You are an English proficiency rater who must assign a CEFR level (A1, A2, B1, B2, C1, or C2) to a single sentence using the provided criteria.

After this, we directly inserted the English descriptions of the CEFR criteria for each level from the corresponding Wikipedia page[1].

For the user input, we used the following prompt:

> You must output exactly one label token (A1, A2, B1, B2, C1, or C2) with no explanation.
>
> User: Sentence: "sentence" Respond with exactly one of: A1, A2, B1, B2, C1, C2.
>
> Assistant:

For Qwen3 instruct models, we additionally appended "`\nDo not output anything else. Answer: `" at the end in order to constrain the response to a single label only.

Table 1: Number of parameters in the embedding models

Model	Number of parameters (M)
`modernbert`	394.8
`intfloat/e5-large-v2`	335.1
`BAAI/bge-large-en-v1.5`	335.1
`intfloat/multilingual-e5-large-instruct`	559.9
`sentence-transformers/LaBSE`	470.9
`microsoft/deberta-v3-large`	434.0
`sentence-transformers/sentence-t5-large`	737.7
`sentence-transformers/sentence-t5-base`	222.9
`sentence-transformers/all-roberta-large-v1`	355.4
`Alibaba-NLP/gte-large-en-v1.5`	434.1
`hkunlp/instructor-large`	737.7

4.2 Embedding Models Used

The alignment measure of [6] estimates a single direction w using the differences between class centroids for each CEFR level, and measures the degree of constraint violation by the inner product with w. In this study, we implemented the aforementioned "exactw" as well as "most2," which uses the difference between the centroids of the two most frequent labels. The embedding models used for comparison are shown in Tab. 1. Except for ModernBERT, the names correspond to the model names on Hugging Face (`https://huggingface.co/`).

5. EXPERIMENTAL RESULTS

Let us first restate the goal of this study. We first assign difficulty labels using an LLM. We then use various methods to identify, from those difficulty labels, the cases that are likely to disagree with human raters. Because the CEFR-SP dataset used in this study contains two human raters, we conducted experiments for both disagreement with Rater A and disagreement with Rater B. As noted above, higher values indicate better performance in predicting disagreement for all evaluation metrics, including ROC-AUC, PR-AUC, and Precision@20, which we abbreviate as p@20 in the tables. Tab. 2 and Tab. 3 show the results when GPT-OSS-120B was used for difficulty labeling, whereas Tab. 4 and Tab. 5 show the results when Qwen3 was used for difficulty labeling. Methods with *logprob* in their names are the conventional baselines that use the token generation probabilities of each LLM's output labels. Because no previous method has proposed using embedding vectors separate from the LLM itself, all other methods are proposed methods.

The *exactw* method uses, as the direction of $\mathbf{w}$, the average of all pairwise constraints. In contrast, *most2* uses as $\mathbf{w}$ the direction of the difference between the mean vectors of the two levels that were assigned most frequently and second most frequently by the LLM.

First, across all four combinations of GPT-OSS-120B or Qwen3 with Rater A or B, modernbert (most2) achieved higher PR-AUC than the conventional logprob-based method. Previously, the only option was to use the confidence scores output by the LLM at the time of response generation, and once these were not collected during generation, it was difficult to obtain them again afterward. By contrast, the proposed method makes it possible to obtain, after the response has already been generated, a more effective indicator of confidence for LLM-as-a-Judge. This is a novel and practically useful result.

Second, *for most embedding models, including modernbert, most2 performed better than exactw.* This is an important finding. A likely reason is that the difficulty level labels assigned by each LLM are not evenly distributed. Rather than measuring consistency with the embedding space while also taking into account instances assigned to infrequent levels, better performance was obtained, from the perspective of detecting the magnitude of disagreement with human raters, by closely examining the levels most frequently assigned by the LLM and measuring their consistency with the embedding space.

Furthermore, although various embeddings were tested, *overall, modernbert showed strong performance.* ModernBERT [14] is a method that comprehensively improves upon BERT, and like BERT, it is designed not for a specific dataset but for broad use of embedding vectors across a wide range of tasks. The proposed method in this study uses modernbert in a way that is consistent with its original design intention. It is therefore reasonable to interpret the result as showing that, even with a relatively small number of parameters, an embedding model used in accordance with its intended design is the most useful.

6. DISCUSSION AND LIMITATIONS

Table 2: Evaluation metrics for GPT-OSS-120B (Rater A)

Method (Rater)	ROC-AUC	PR-AUC	p@20
logprob_label (A)	0.561	0.579	0.80
p_i exactw / chain (A)	0.509	0.528	0.55

`instructor-large`	0.530	0.668	1.00

The proposed method should be understood as a method for detecting potentially unreliable difficulty labels in settings where the target difficulty construct is ordinal and is at least partly reflected in an independent representation space. In this study, we evaluated the method on a CEFR-based English sentence difficulty assessment. This is a favorable setting for the proposed approach because the target construct is linguistic difficulty, and text embedding models such as ModernBERT are expected to encode lexical, syntactic, and semantic properties that are relevant to language proficiency levels.

This scope is important. The proposed method is not intended to be a domain-independent solution to all forms of educational difficulty assessment. In particular, difficulty in Science, Technology, Engineering, and Mathematics (STEM) domains may depend on conceptual prerequisites, problem-solving procedures, mathematical structure, required operations, common misconceptions, and the interaction between textual and non-textual representations. These factors may not be adequately captured by standard text embeddings.

Table 4: Evaluation metrics for Qwen3 (Rater A)

Method (Rater)	ROC-AUC	PR-AUC	p@20

In such cases, geometric consistency in a generic embedding space may reflect lexical or semantic similarity rather than the educational difficulty of the item.

Therefore, applying the proposed method to STEM difficulty assessment would require additional domain-specific assumptions and validation. One possible direction is to replace the generic text embedding space with a representation that incorporates prerequisite relations, knowledge-component annotations, worked-solution structure, or other features that are known to be relevant to the target domain. Another requirement is a reliable ordinal difficulty scale with sufficient agreement among human raters, comparable in role to CEFR in the present study.

Accordingly, the main contribution of this paper is not that embedding geometry universally determines educational difficulty. Rather, the contribution is to show that, in language-based difficulty assessment, an independently obtained embedding space can provide a practical and probability-free signal for prioritizing LLM-generated ratings that are likely to disagree with human raters. Relatedly, language-resource work has shown that leveled wordlists can encode different register assumptions that are recoverable from general corpora [8], and inverse-embedding work has suggested that difficulty-related directions in embedding spaces may be diverse rather than unique [7]. Extending the present disagreement detection approach beyond language difficulty assessment is an important direction for future work, but it should be treated as a domain-specific research problem rather than as a direct application of the present method.

7. CONCLUSION

In this study, we proposed a reliability indicator for individual difficulty labels assigned by LLM-as-a-Judge that is easier to obtain and more effective than conventional probability-based approaches. Unlike prior methods, our method requires only the LLM-assigned labels and the original text, without relying on generation-time confidence scores. The method exploits the fact that difficulty is an ordinal scale and measures, for each label, the geometric consistency between an additional embedding space and the difficulty labels assigned by the LLM. Experiments on CEFR-SP showed that the proposed method can detect labels likely to disagree with human raters more accurately than conventional methods. It is also memory-efficient, because it uses only text embedding models with fewer than 1B parameters.

As future work, although this study was evaluated on English text difficulty assessment, extending the method to STEM subjects will require establishing a rigorous difficulty scale comparable to CEFR across human raters. If such a scale can be developed, the proposed method may also be applied to STEM difficulty assessment.

ABSTRACT

Understanding student problem-solving strategies in educational robotics is important for developing adaptive instructional support. However, most research in this area focuses on final outcomes rather than the underlying processes. In this exploratory paper, we use first-order Markov chains to model programming strategies used by high school students working with LEGO SPIKE Prime robots. Fine-grained interaction traces are transformed into structured action sequences and compared between low- and high-performing student groups using likelihood-ratio testing and standardized residual analysis. Even in the first task, the Markov chains reveal statistically significant behavioral differences that grow with task complexity, with high-performing students showing more systematic, goal-directed behavior and low-performing students showing more searching, reorganization, and trial-and-error. These exploratory findings suggest that process data from robotics environments can reveal meaningful differences well before final outcomes.

Keywords

Educational robotics, Markov chains, student programming strategies, block-based programming

1. INTRODUCTION

Educational robotics draws heavily on constructivism and Papert's idea that learners develop powerful ideas by building and debugging tangible artifacts [14]. Multiple reviews confirm that robotics activities can improve engagement and learning outcomes [3, 2, 11]. However, the vast majority of studies evaluate these benefits through pre- and post-tests or final solution assessments [13, 20]. This focus on outcomes is at odds with the constructivist premise: in a robotics programming task, iterative debugging and refinement is central, not incidental. Two students can arrive at the same correct solution through very different sequences of exploration, debugging, and self-regulation. An analysis of these processes, rather than only their endpoints, may yield actionable insights for instructors and adaptive systems.

Process-level analysis has gained traction in block-based programming research more broadly. Dong et al. [6] analyzed trace data from Snap! to detect struggling moments and identify when intervention might be needed. Filvà et al. [7] modified Scratch to log every interaction and used those traces to identify behavior profiles and predict performance. Fu et al. [8] showed that process features extracted from MixToy improve student performance prediction. Beyond block-based environments, trace-based analysis has a longer history in text-based programming contexts, where IDE interaction logs have been used to study debugging strategies [10, 4] and to detect productive versus unproductive programming patterns [15]. However, research that applies interaction trace analysis to educational robot programming specifically remains sparse. Scaradozzi et al. [17] collected and analyzed data from LEGO Mindstorms EV3 workshops to extract problem-solving pathways across student teams. We applied clustering to programming trace data from robotics workshops to study students' programming strategies [21].

Given the sequential nature of trace data, Markov chains are a natural modeling choice. Hensen et al. [9] modeled interactions with a math learning platform as a single Markov chain per student. The resulting chains were subsequently clustered to draw conclusions about different behavioral types. Markov chain transition probabilities have also been used as inputs for a neural network trained to predict student performance [16]. Aside from simple Markov models, Hidden Markov Models are also widely used for modeling learning processes [5, 19], with the hope that hidden states can represent higher-order behaviors than raw interaction logs.

In this work, we present an exploratory process-level analysis of students' block-based programming with LEGO Education SPIKE Prime robots [12]. We propose a four-step pipeline: (1) extraction of semantically meaningful action sequences from raw interaction traces, (2) construction of task-specific first-order Markov chains for high- and low-performing groups, (3) likelihood-ratio testing to identify statistically significant group differences, and (4) standardized residual analysis to pinpoint the transitions that contribute most to these differences. **Our contribution is threefold**: (1) we present, to our knowledge, the first application of Markov-chain process analysis to block-based educational robotics programming, extending a method established in screen-only block environments [7, 8] to a tangible-artifact context; (2) we demonstrate that strategy differences are

detectable in the very first task, before any problem-solving demands, suggesting that early process signals can precede outcome signals by an entire workshop; (3) we identify specific transition patterns (run–reorganize–run, remove-and-rebuild, attention-spreading across irrelevant block types) that are candidate features for adaptive support.

2. DATA COLLECTION AND SEQUENCE EXTRACTION

A total of 97 first-year students (average age = 15.22, SD = 0.35) from a public high school participated[1] in the study during regular class hours. Each 90-minute lesson was delivered as part of the existing programming curriculum. Students programmed a pre-built LEGO SPIKE Prime Break Dancer robot in the accompanying block-based environment based on Scratch. The programming environment features a left panel containing available blocks categorized by type and a right-side canvas where programs are constructed by dragging, connecting, modifying, and removing blocks.

Participants completed six programming tasks arranged in increasing difficulty, structured to build foundational concepts while managing cognitive load. Task 1 introduced the programming interface by asking students to copy a simple motor program from a reference image. Task 2 required students to independently program both arm and leg motors. Task 3 asked students to set specific parameter values (e.g., move legs by 375° at 30% speed and arms for 5 s at 50% speed). Tasks 4–6 progressed into simultaneous motor coordination, conditional logic with sensors, and an open-ended capstone activity. Throughout the workshop, we captured mouse and keyboard interaction data, took screenshots at each mouse event, and recorded complete program snapshots following every modification.

The raw data was transformed into action sequences representing students' interactions with the programming environment. We extracted five action types: block ADDED, block REMOVED, block MOVED, block MODIFIED, and RUN. The RUN action was detected via a computer vision algorithm that identified yellow circular UI elements (the run button) in captured screenshots. The remaining actions were derived by comparing abstract syntax trees (ASTs) of consecutive program snapshots. ADDED indicated a new block on the canvas, MODIFIED indicated a parameter change within an existing block, and REMOVED and MOVED captured deletion or repositioning. Because MOVED and REMOVED actions could affect multiple blocks simultaneously (e.g., dragging a root block also moves all subsequent blocks), we aggregated them into single actions while recording the number and types of affected blocks.

After extracting sequences and evaluating each student's solutions, 76 complete instances remained for analysis. The reduction from 97 to 76 resulted from excluding students with incomplete data: those who missed part of the workshop, experienced technical failures in data recording, or whose solutions could not be reliably evaluated. Summary statistics are shown in Table 1.

[1]The study protocol was reviewed and approved by the Ethics Committee of the University of Zagreb Faculty of Electrical Engineering and Computing. Informed consent in accordance with GDPR was obtained from both participating students and their parents or legal guardians prior to the workshop. All interaction data were pseudonymized at collection, and no personally identifying information is retained in the analysis dataset.

Table 1: Summary Statistics of the Data.

Statistic	Value
Average sequence length	280.09 ± 111.52 events
Number of unique states	38
Total transitions counted	45,396
High performers (top 25%)	20 students
Low performers (bottom 25%)	17 students

3. METHOD

Our main goal in this exploratory study is to ascertain whether students' programming process can be meaningfully analyzed using trace data from the LEGO block-based environment. To this end, we categorized students into high-performing (top 25% by assessment score) and low-performing (bottom 25%) groups and tested for statistical differences between their processes. We adopted this extreme-group design rather than a median split because our exploratory aim is to surface qualitatively distinct strategic patterns: trimming the middle 50% maximizes behavioral contrast between groups and reduces noise from students near the score median, who tend to differ less in programming strategy than in incidental factors such as time on task or momentary attention. This design is well suited to identifying which transitions distinguish strategies; estimating population-level effect sizes is left to future work with larger samples. Because students varied substantially in time on task and total number of actions, raw transition counts are not directly comparable across groups. We therefore constructed, for each group and task, a first-order Markov chain in which states corresponded to the action–block-type combinations described above, and based all subsequent analyses on transition probabilities rather than raw counts.

Transition probabilities were estimated by tallying the frequency of each transition across all students within a given group. Although the first-order assumption is clearly simplified, transition probabilities are influenced by many factors beyond the immediately preceding state, more complex models would be impractical given the relatively small sample size per task. The first-order model proved sufficient to capture meaningful patterns.

The MOVED and REMOVED actions presented a methodological challenge, as they could affect multiple block types simultaneously (e.g., moving a motor block that is connected to a control block moves both). To address this, we counted all pairwise combinations of affected states. For instance, if a student moved motor and sensor blocks and subsequently removed event and control blocks, we incremented the count for each combination: *Moved Motor* → *Removed Event*, *Moved Motor* → *Removed Control*, *Moved Sensor* → *Removed Event*, and *Moved Sensor* → *Removed Control*. Because this pairwise expansion could in principle inflate transition counts for connected subgraphs, we examine its

impact in Section 4.4 by comparing against an alternative encoding that attributes each composite event only to the block type that the student directly grabbed.

A likelihood-ratio test [1] was used to determine whether observed differences between the two groups were statistically significant rather than attributable to sampling variability. This test is particularly important for early tasks, where transition counts are low due to the simplicity of the activities. Following a significant difference, we computed standardized residuals:

$$r_{ij} = \frac{O_{ij} - E_{ij}}{\sqrt{E_{ij}}}, \tag{1}$$

where O_{ij} and E_{ij} denote observed and expected transition counts under the null hypothesis that both groups share the same underlying Markov chain. Expected counts were computed by pooling all sequences, calculating transition frequencies, normalizing them per state, and multiplying by each group's total transitions. Differences between groups were quantified as:

$$r_{ij}^{\textbf{diff}} = r_{ij}^{\text{high}} - r_{ij}^{\text{low}}. \tag{2}$$

Standardized residuals quantify the difference between the observed counts and the counts that we would expect to see if both groups shared the same underlying stochastic process. Furthermore, standardized residual analysis accounts for differing group sizes and normalizes transition counts into comparable distributions, allowing it to identify which transitions drive these differences.

Positive values indicate transitions more frequent among high performers; negative values indicate transitions more common among low performers. Following [18], $|r_{ij}^{\text{diff}}| > 2$ is considered notable and $|r_{ij}^{\text{diff}}| > 3$ highly notable.

4. RESULTS

The high- and low-performer groups originate from statistically different Markov chains on all six tasks ($p < 0.01$). Throughout, we interpret the observed transition patterns in terms of the programming environment's mechanics and the task requirements; these interpretations are intended as plausible explanations to guide future research rather than as established causal claims. We restrict the analysis to Tasks 1–3 because these tasks have the most complete data, all 76 students contributed sequences, whereas later tasks are affected by attrition among low-performing students who did not finish the workshop.

4.1 Task 1: Copying a reference program

The standardized residual differences for Task 1 are shown in Figure 1. Although this task involved only copying code from a reference image and required no debugging or problem-solving, the estimated Markov chains for high- and low-performing students differed significantly ($G = 54.44$, $df = 33$, $p < 0.01$).

The largest residual difference corresponds to the transition Modified Motor → Added Motor ($r = -3.04$), indicating that low-performing students frequently added new motor blocks after modifying existing ones. In the programming environment, this transition means a student changed parameters on an existing motor block and then dragged a new motor block from the side menu onto the canvas. Since the task only requires placing the correct blocks and setting values, repeatedly returning to the menu after modifying a block suggests uncertainty about which block is needed. In contrast, high-performing students more often followed the transition Added Motor → Modified Motor ($r = 2.51$), reflecting a more systematic strategy of first selecting the appropriate block and then refining its parameters.

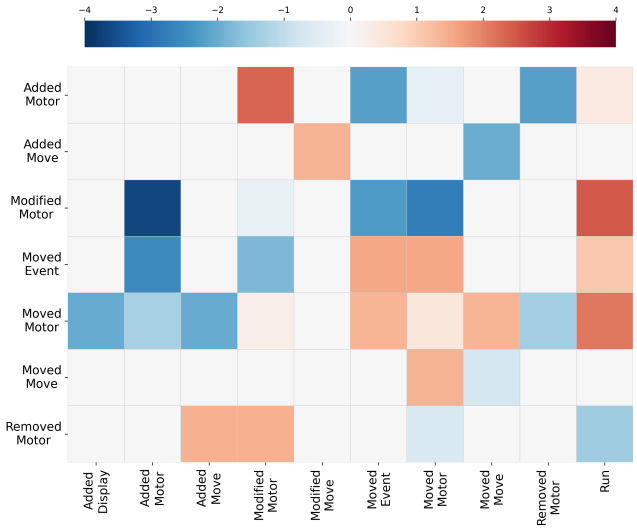

Figure 1: Standardized residual differences (high − low) for Task 1. Rows denote current states and columns denote subsequent states; states with $|r| < 1.0$ are omitted.

Additional low-performer transitions involved event block movements: Moved Event → Added Motor ($r = -2.56$) and Added Motor → Moved Event ($r = -2.09$), suggesting that these students spent time repositioning the program's starting event block alongside their block-searching behavior. Notably, these differences emerge despite the absence of genuine problem-solving demands in the task, suggesting that they reflect differences in familiarity with the interface or approach to the task rather than debugging strategy.

4.2 Task 2: Independent multi-motor programming

Figure 2 shows the standardized residual differences for Task 2 ($G = 62.35$, $df = 40$, $p < 0.01$). In this task, students were asked to independently program both arm and leg motors, and behavioral differences became more pronounced as students began reorganizing their programs.

Low-performing students exhibited substantially more transitions involving movement and modification of move blocks, particularly Added Move → Modified Move ($r = -3.06$) and Modified Move → Moved Move ($r = -3.61$). These patterns indicate frequent restructuring of code: students added move blocks, changed their parameters, and then repositioned them on the canvas. This behavior is consistent with a trial-and-error approach in which students tested partial solutions and subsequently reorganized blocks when the outcome did not match expectations. Importantly, move

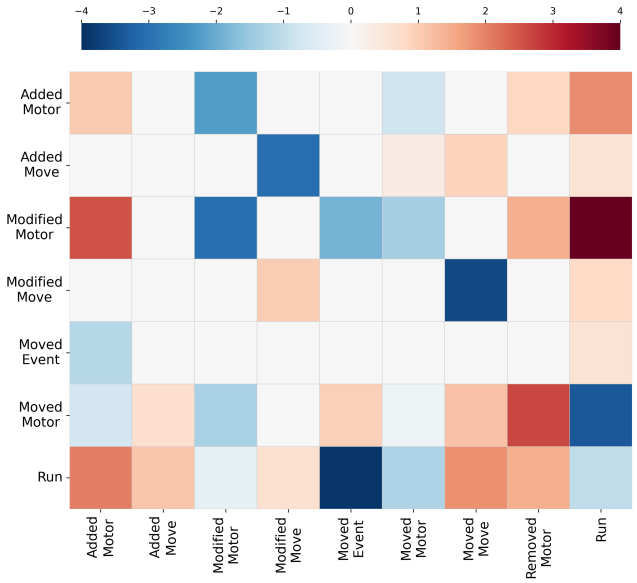

Figure 2: Standardized residual differences (high − low) for Task 2. Rows denote current states and columns denote subsequent states; states with $|r| < 1.0$ are omitted.

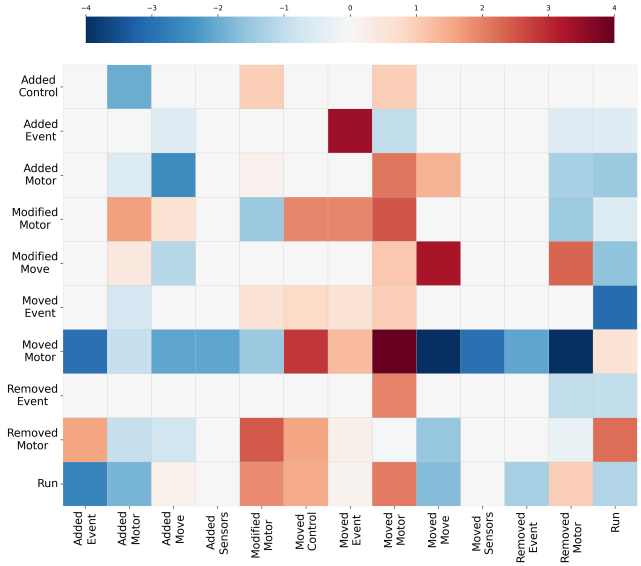

Figure 3: Standardized residual differences (high − low) for Task 3. Rows denote current states and columns denote subsequent states; states with $|r| < 1.9$ are omitted.

blocks were not covered in Task 1, and the subsequent tasks were designed to be solvable using only the previously introduced motor blocks. While Task 2 could technically be solved using move blocks, none of the students successfully did so, meaning these move block manipulations represent unproductive exploration.

A further notable transition was Run → Moved Event ($r = -3.90$), indicating that low-performing students frequently repositioned event blocks immediately after running their programs. Combined with Moved Motor → Run ($r = -3.03$), this pattern suggests a cycle of run–reorganize–run characteristic of unsystematic debugging. High-performing students, by contrast, showed fewer such reorganizations and more direct transitions between adding motor blocks and running (Added Motor → Run, $r = 1.98$; Run → Added Motor, $r = 2.04$), indicating a more stable and anticipatory approach to constructing the program.

4.3 Task 3: Parameter tuning and block ordering

Figure 3 presents the standardized residual differences for Task 3 ($G = 174.54$, $df = 104$, $p < 0.001$). This task required students to set specific motor parameters (e.g., 375° at 30% speed for legs, 5 s at 50% speed for arms), and the common error was placing the speed block after the movement block rather than before it. By this point, differences between groups were both larger in magnitude and more diverse in nature.

A key difference emerged in how students handled block ordering. Low-performing students more often moved motor blocks and then removed them (Moved Motor → Removed Motor, $r = -5.06$), the largest residual for this task, suggesting recognition of incorrect ordering without successfully correcting it through repositioning. Instead, they deleted blocks and re-added them. In contrast, high-performing students more frequently performed consecutive move operations on motor blocks (Moved Motor → Moved Motor, $r = 3.73$), indicating deliberate reordering of the existing program structure rather than removal and reconstruction. High performers also showed a stronger Moved Motor → Run transition ($r = 2.59$), suggesting that after reordering blocks they tested the result, consistent with a hypothesis-driven approach.

Low-performing students were more likely to follow motor movements with structural changes to unrelated block types (Moved Motor → Moved Move, $r = -3.26$; Moved Motor → Moved Sensors, $r = -2.66$; Moved Motor → Added Event, $r = -2.66$), spreading their attention across multiple block categories rather than focusing on the motor blocks central to the task. They also more frequently added motor blocks after running (Run → Added Motor, $r = -2.82$), consistent with a cycle of testing and then starting over with new blocks rather than modifying the existing program.

4.4 Sensitivity to composite-action encoding

To assess whether the pairwise encoding of composite MOVED and REMOVED actions biased the results, we recomputed the Markov chains under a *root-only* alternative in which only the block type that the student directly grabbed contributes to the transition; downstream blocks in the dragged subtree are ignored. This scheme avoids any inflation of transition counts from connected subgraphs at the cost of discarding information about which block types co-occur in composite operations.

The qualitative findings are stable across both encodings. The likelihood-ratio tests remain significant on every task under both schemes (Task 1: $p = 0.011/0.020$; Task 2: $p = 0.013/0.019$; Task 3: both $p < 10^{-4}$), and the ranking, magnitude, and sign of the largest residuals are preserved (Table 2). Across Tasks 1–3, 8–9 of the top-10 transitions per task appear in both schemes; transitions that move in or out are predominantly those near the notability threshold of $|r^{\text{diff}}| = 2$. This indicates that the strategy differences reported in Sections 4.1–4.3 reflect genuine behavioral contrasts rather than artifacts of how composite actions are decomposed.

Table 2: Stability of the largest residuals across encoding schemes (Tasks 1–3). Values are r^{diff} under the pairwise (default) and root-only schemes. The final column indicates whether the transition appears in the top-10 of both schemes for the corresponding task.

T	Transition	Pair.	Root	Top-10
1	Mod. Motor → Add. Motor	−3.04	−3.10	both
1	Add. Motor → Mod. Motor	2.51	2.16	both
1	Mov. Event → Add. Motor	−2.56	−2.00	both
1	Add. Motor → Rem. Motor	−2.09	−2.30	both
1	Add. Motor → Mov. Event	−2.09	−2.30	both
2	Run → Mov. Event	−3.90	−4.02	both
2	Mod. Move → Mov. Move	−3.61	−3.61	both
2	Add. Move → Mod. Move	−3.06	−2.99	both
2	Mov. Motor → Run	−3.03	−2.60	both
2	Mod. Motor → Mov. Motor	−2.70	−2.07	both
3	Mov. Control → Rem. Control	−6.07	−4.82	both
3	Mov. Motor → Rem. Motor	−5.06	−5.37	both
3	Mov. Motor → Mov. Motor	3.73	3.08	both
3	Mod. Move → Mov. Move	3.66	3.61	both
3	Run → Add. Motor	−2.82	−2.85	both
3	Mov. Motor → Run	2.59	2.54	both

5. DISCUSSION

The Markov-chain analysis surfaces three patterns that together sketch a coherent picture of how high- and low-performing students engage with the programming environment. We discuss each in turn, relate it to prior work, and consider its implications for instructional design.

The most striking finding is that Task 1, which required only copying a reference program, already produces statistically significant group differences. Low-performing students repeatedly returned to the block palette after modifying existing blocks (*Modified Motor* → *Added Motor*), while high performers more often followed the reverse sequence. Because the task has no debugging component, the contrast cannot be attributed to differential problem-solving skill; a more plausible reading is that it reflects differences in interface familiarity or in how students plan a sequence of actions before executing it. The practical implication is that process-level signals can precede outcome-level signals by an entire workshop, echoing Jadud's broader argument [10] that trace data serves as a *formative* indicator where assignments and exams only offer *summative* ones, and opening a window for instructional support before students have visibly fallen behind.

A second pattern emerges in Task 2, where low performers exhibit a clear *Run* → *Moved Event* → *Run* cycle together with disproportionate exploration of move-type blocks that none of the students used productively. This is precisely the kind of behavior Dong et al. [6] identify as a "struggling moment" in Snap!: extended periods of activity without meaningful progress, which they argue warrant proactive intervention. Our contribution is to show that these patterns are detectable in a robotics environment with a substantially smaller behavioral vocabulary (38 action–block-type combinations), and that the transitions themselves carry the signal. A natural application is real-time detection: when a student's recent trace shows a high rate of *Run* → *Move* transitions on irrelevant blocks, an adaptive system could surface a reflection prompt asking the student to predict the outcome before the next run.

Task 3 produces the largest residual in the study: low performers recognized incorrect block ordering but resolved it by deletion and reconstruction (*Moved Motor* → *Removed Motor*) rather than repositioning. High performers instead produced consecutive move operations followed by a run, consistent with hypothesis-driven debugging. This mirrors the distinction Piech et al. [15] draw between alpha and gamma trajectory clusters, though their patterns emerge at the level of entire development paths while ours localize to specific transitions. Pedagogically, explicit instruction that blocks can be reordered without being removed could reduce the cost of correction for students who default to deletion. More generally, these transitions are candidate features for the kind of adaptive support that Fu et al. [8] build from aggregate event and sequence features, with the advantage that transition-level signals are directly interpretable as moments where intervention could be inserted.

Taken together, these patterns suggest transition-based indicators that could drive lightweight adaptive support without requiring full sequence modeling, whether through automated prompts or instructor dashboards. The patterns are also entirely behavioral; combining trace data with psychological instruments, eye-tracking, or verbal protocols in future workshops would help disambiguate whether the differences reflect cognitive load, prior experience, or self-regulation.

6. CONCLUSION

This exploratory work-in-progress demonstrates that first-order Markov chains applied to fine-grained programming traces can reveal meaningful behavioral differences between high- and low-performing students in educational robotics, with differences detectable already in the first task, before any problem-solving is required. The consistency of the patterns across tasks suggests Markov chain analysis is a promising tool for surfacing strategic differences well before final outcomes, and the pipeline itself is not specific to the LEGO SPIKE Prime environment but applies to any block-based platform supporting program snapshot extraction. The primary limitation is that data comes from a single workshop context; future work should replicate the analysis across different cohorts and curricula, and evaluate the identified transition patterns as real-time indicators for adaptive instructional support.

ABSTRACT

The emergence of Large Language Models (LLMs) has renewed interest in automated essay scoring, yet a barrier to adoption persists: LLM-generated scores are sensitive to prompt formulation, and it is unclear which aspects of a prompt drive this effect or whether findings from one model or institution transfer to another. For educators and institutions considering deployment, this uncertainty is consequential, as without understanding the structure of prompt sensitivity, there is no principled basis for deciding whether to trust an LLM-generated score. This study evaluates three frontier LLMs (GPT-5.4, Claude Opus 4.6, Gemini 3 Flash) across a $3 \times 3 \times 3$ factorial design varying criteria specificity, calibration intervention, and scoring strategy on a calibration sample of 153 undergraduate essays from three UK universities with distinct marking conventions. A main-effects ANOVA on the 27 per-model conditions reveals that prompt sensitivity is substantial but strikingly model-specific: criteria specificity accounts for the largest share of condition-level variance for Gemini (57%, $p < .001$), scoring strategy for GPT (35%, $p < .01$), and scoring strategy and calibration together for Claude (32% and 24% respectively), with no single dimension dominating across models. The optimal configuration also differs across institutions, even within the same model. At each institution, the gap between best and worst configurations spans 4–5 RMSE points on the calibration set, with the worst performing worse than a naïve baseline. For the models tested, these findings indicate that no universal prompt recipe exists, and that responsible deployment requires empirical prompt calibration as a prerequisite rather than an optional refinement – a process more similar to hyperparameter tuning than to simple instruction design.

automated essay scoring, large language models, prompt engineering, hyperparameter tuning

1. INTRODUCTION

The emergence of LLMs has renewed interest in automated essay scoring, with recent work demonstrating that individual models can approximate human scores on standardised tasks [5, 3]. However, a practical barrier to deployment persists: LLM-generated scores are sensitive to prompt formulation, with minor variations in rubric framing or role instructions capable of shifting outputs by a full grade band [1]. For institutions considering the use of LLM-based scoring, this sensitivity is consequential yet poorly understood, and it is unclear whether the effect follows patterns that can inform principled prompt design or whether it is contingent on the specific model and context in use.

Despite this known limitation of LLM-based grading, prompt design for essay scoring is typically treated as a fixed authoring choice, selected on the basis of practitioner intuition. Where studies do evaluate prompt effects, they tend to do so by sequentially adding prompt components within a single model and selecting whichever configuration maximises agreement – an approach that can identify that prompts matter, but not which dimensions of a prompt matter, nor whether those dimensions generalise across models [6, 4]. This leaves two open questions. The first is about decomposition: given that prompt formulation affects LLM-generated scores, which types of prompt intervention are actually responsible for the effect, and how much of the variance does each explain? The second is about generalisability: do the answers to the first question hold across models, or is prompt sensitivity model-contingent in ways that make universal recommendations impossible? The distinction is consequential: if one prompt dimension consistently dominates, practitioners can follow a simple prompting framework; if the dominant dimension varies by model, then empirical calibration is not a convenience but a necessity.

This study addresses that question directly. Three prompt dimensions – targeting what evaluative structure the model

receives, how it is distributionally anchored, and how it is asked to reason – are independently varied in a $3 \times 3 \times 3$ factorial design across three LLMs, yielding 81 model-prompt conditions evaluated on a calibration set of 153 undergraduate essays from three UK institutions. The factorial structure permits decomposition of not only which prompt components matter, but whether they matter in the same way across models.

The contribution of this work, and what attendees will see at the poster, is twofold. First, a per-model variance decomposition that makes the dimensions of prompt sensitivity visible rather than aggregating them into a single "prompts matter" headline. Second, an empirical demonstration that the optimal prompt configuration differs not only across models but also across institutions with distinct marking conventions, with the practical implication that institutions cannot import a prompt validated elsewhere and expect it to behave consistently on their own essays. The poster will display the full grid of 81 conditions alongside the per-institution best/worst gaps, allowing attendees to inspect the model-specific patterns directly and to consider what an empirical calibration workflow would look like in their own context.

2. METHODS

2.1 Dataset

The data is drawn from a corpus of 764 long-form undergraduate psychology essays from three UK universities, spanning 50 modules. All were online submissions of coursework and exam scripts marked by human assessors using the standard UK percentage scale with discrete tick marks (e.g., 62, 65, 68, 72; $M = 63.5$, $SD = 10.1$). A stratified 80/20 split produced a calibration set ($n = 153$, approximately 50 per institution) and a held-out test set ($n = 611$). All analyses in this paper use the calibration set only. The decision to reserve the test set is deliberate rather than incidental: the research question addressed here concerns the structure of prompt sensitivity, which requires evaluating the same essays under all 81 model–prompt conditions and decomposing the resulting variance. The held-out essays are reserved for a separate, downstream question – whether configurations selected through calibration generalise to unseen submissions – which will be addressed in subsequent work and would be premature to evaluate before the present decomposition is established.

2.2 Factorial Design

The three LLMs used – GPT-5.4 (OpenAI), Claude Opus 4.6 (Anthropic), and Gemini 3 Flash (Google) – were selected from different providers to maximise diversity of biases and failure modes. Three prompt dimensions were varied in a fully crossed $3 \times 3 \times 3$ design (Figure 1). The dimensions were chosen to span three theoretically distinct sources of prompt influence: *what* evaluative structure the model receives (criteria specificity), *how* it is distributionally anchored (calibration intervention), and *how* it is asked to arrive at a judgement (scoring strategy). Together, these cover the input-side, distributional, and process-level determinants of LLM scoring behaviour.

(A) Criteria specificity addresses how much evaluative structure the model receives. Prior work has shown that rubric provision can either improve consistency or introduce dimension level artefacts [1], but the relationship between rubric granularity and accuracy has not been isolated. Three levels were tested: no rubric (A1), summary grade boundaries (A2; e.g., "70+: demonstrates critical analysis and original insight"), and the full analytic rubric for a given assignment with per-dimension performance descriptors (A3).

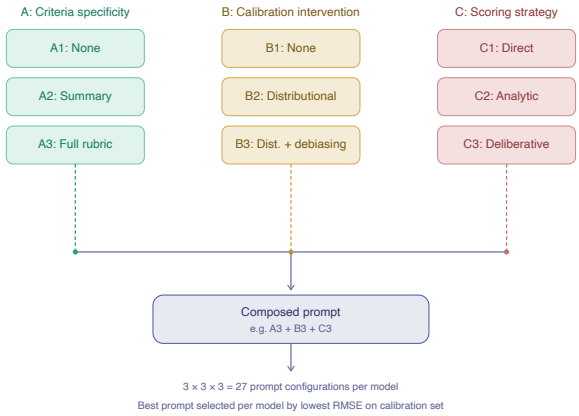

Figure 1: Factorial prompt composition. Three dimensions are crossed in a $3 \times 3 \times 3$ design, yielding 27 prompt configurations per model.

(B) Calibration intervention addresses the well-documented tendency of LLMs to compress scores towards the centre of the scale [2], which can in principle be mitigated by providing distributional anchoring. Three levels were tested: no calibration (B1), distributional base-rate information (B2; e.g., "approximately 25% of essays in this cohort receive a First"), and distributional information with an explicit debiasing instruction (B3; e.g., "...be aware that LLMs tend to compress scores towards the mean").

(C) Scoring strategy addresses how the model is asked to arrive at its judgement, drawing on the distinction between analytic and holistic scoring approaches in educational assessment. Three levels were tested: holistic-direct scoring with no structured reasoning (C1), analytic-decomposed scoring in which the model evaluates the essay separately on substantive quality, use of evidence, and clarity of expression before synthesising a single overall score (C2), and holistic-deliberative scoring in which the model first identifies the appropriate grade band, weighs evidence for and against that classification, and then assigns a specific mark within it (C3).

Each model scored the calibration set ($n = 153$) under all 27 conditions. The best-performing prompt per model was selected by lowest RMSE, independently for each institution. Both prompt selection and the variance decomposition reported below use this same calibration partition. This is appropriate to the research question – which prompt dimensions drive scoring variance – but means that the per-institution best/worst comparisons reflect in-sample performance and are subject to optimistic selection bias, as discussed in Section 3.1.

Table 1: Best and worst model–prompt conditions per institution on the calibration set ($n = 153$). Naïve baseline = predicting the cohort mean. Best/worst are selected as min/max RMSE across 27 conditions; the observed gap is therefore an in-sample upper bound on the true best–worst difference (see text).

Institution	Condition	Model	RMSE	BA (%)	Δ RMSE	Δ BA
Inst. A	Best (A3_B3_C1)	Gemini	5.84	74.1		
	Worst (A1_B1_C1)	Claude	10.94	48.1	+5.09	−25.9
	Naïve baseline	–	6.95

3. RESULTS

3.1 The Magnitude of Prompt Effects

Before decomposing which prompt dimensions drive scoring variance, it is important to establish the practical magnitude of the effects at stake. Table 1 presents the best and worst model–prompt conditions for each institution on the calibration set. The in-sample gap between optimal and worst-case conditions spans 3.8–5.1 RMSE points and up to 26 percentage points of band accuracy. At Institution A, the best condition (Gemini, A3_B3_C1) achieves an RMSE of 5.84 with 74.1% band accuracy; the worst (Claude, A1_B1_C1) yields 10.94 and 48.1%.

An important caveat applies: because the "best" and "worst" configurations are selected as the extremes across 27 conditions, the observed gap is subject to selection optimism and will tend to overstate the true best–worst difference on new data. The gap is too large to be explained entirely by sampling variability – the best conditions consistently fall below the naïve baseline while the worst fall above it – but the precise magnitude should be interpreted as an upper bound. Future work will evaluate whether the gap holds on the reserved test set ($n = 611$).

The comparison with the naïve baseline – predicting the cohort mean for every essay – is what makes these differences consequential rather than merely descriptive. The best-calibrated conditions fall below this baseline, indicating that they extract genuine evaluative signal from the essay text. The worst conditions fall clearly above it, meaning that a poorly chosen prompt actively destroys signal that a trivial heuristic would preserve. The difference between a good and bad configuration is therefore not one of marginal refinement but of whether the system functions at all – a point that the poster will make visible by displaying the full distribution of the 27 per-model conditions against the baseline, so that the magnitude of the best–worst spread can be inspected rather than inferred.

Table 2: Condition-level ANOVA: proportion of variance (η^2) in per-condition RMSE explained by each prompt dimension, estimated separately for each model ($n = 27$ conditions per model, 20 residual df). Bootstrap 95% CIs (10,000 resamples) in brackets. $^{*}p < .05$, $^{**}p < .01$, $^{***}p < .001$.

Dimension	Claude	GPT	Gemini
A: Criteria	ns	ns	57%*** [29, 78]
B: Calibration	24%* [3, 48]	ns	ns
C: Strategy	32%** [6, 56]	35%** [8, 60]	ns

3.2 Prompt Sensitivity is Model-Specific

The central question of this work is whether prompting effects follow general patterns – in which case a universal best-practice recommendation would be possible – or whether they are model-contingent. A condition-level ANOVA on the 27 per-model RMSE values (Table 2) decomposes variance by prompt dimension under a main-effects model. An important caveat applies throughout: with only 27 observations per model and 20 residual degrees of freedom, the η^2 values are point estimates with wide confidence intervals, not precise effect sizes; we report bootstrap 95% CIs (10,000 resamples) to make this uncertainty explicit. With that in mind, the pattern across models is striking. For Gemini, criteria specificity accounts for the largest share of condition-level variance (57%, 95% CI [29, 78], $p < .001$). For GPT, scoring strategy accounts for 35% (95% CI [8, 60], $p < .01$). For Claude, scoring strategy and calibration together account for over half (32%, 95% CI [6, 56], $p < .01$; and 24%, 95% CI [3, 48], $p < .05$). No single dimension is consistently dominant, and dimensions that are significant for one model are non-significant for another.

Two-way interactions (A×B, A×C, B×C) were tested in a full model including all main effects and two-way terms (residual $df = 8$). No individual interaction reached significance at $\alpha = .05$ for any of the three models, and the

combined interaction terms did not improve model fit over the main-effects specification. Given the limited residual degrees of freedom, these null results should not be taken as evidence that interactions are absent, but they support treating the main-effects decomposition as a reasonable approximation.

This pattern is corroborated by a repeated-measures analysis at the essay level ($n = 153$, each scored under all 27 conditions). Gemini shows the largest total prompt sensitivity (partial $\eta^2 = 2.0\%$, driven by criteria at 1.5%, $p < .001$), Claude shows moderate sensitivity (1.2%, spread across calibration and strategy), and GPT shows the least (0.4%). The within-essay effects are naturally small in relative terms – essay quality dominates individual score variance, as it should. But the practical consequence of prompt sensitivity operates at the system level, not the essay level: small per-essay biases that are systematic across a cohort aggregate into the 4–5 point RMSE differences reported in Table 1. A prompt configuration that introduces a consistent directional bias, for instance, may shift each essay by only 2–3 marks, but across a cohort this is enough to meaningfully alter the RMSE. The model-specificity of the pattern is consistent across both levels of analysis, confirming that the condition-level decomposition reflects a real structural difference rather than an artefact of low power.

With that caveat, the practical implication is clear: scoring strategy appears as the largest single dimension for both Claude and GPT, but the two models differ in which other dimensions matter (calibration for Claude, none for GPT), and Gemini is driven by an entirely different dimension (criteria specificity). A practitioner who reads that "scoring strategy is the most important prompt dimension" and applies this as a general rule will miss the dimension that matters most for Gemini and misconfigure calibration for Claude. For the three models tested here, universal prompt guidelines do not merely oversimplify – they actively mislead.

4. CONCLUSION

Prompt sensitivity in LLM-based essay scoring appears to be real, substantial, and model-specific. No single prompt dimension dominates across the three models tested: scoring strategy is the primary driver for both Claude and GPT, but Claude is additionally sensitive to calibration, while Gemini is driven by an entirely different dimension – criteria specificity. The gap between optimal and worst-case configurations spans 4–5 RMSE points per institution on the calibration set, with poorly chosen prompts performing worse than a naïve baseline – in effect, making the difference between a scoring system that extracts evaluative signal and one that removes it completely. For the models tested here, the results suggest that no universal prompt recipe exists, and that empirical calibration may be better understood as a prerequisite for considering deployment than as an optional refinement.

This pattern carries implications that extend beyond predictive accuracy. Because the optimal configuration varies across both models and institutions, a prompt validated in one setting and imported into another may yield systematically different scores for substantively similar work, with consequences for grading consistency at the cohort level and for the comparability of marks across institutions. The institution-level variation in optimal configurations also suggests that prompt sensitivity is not a purely technical artefact but interacts with local marking conventions, which raises fairness considerations when LLM-generated scores are used to compare students who have been assessed under different rubrics or grade distributions. These implications are tentative given the calibration-only scope of the present analysis, but they indicate that the choice of prompt may need to be treated as part of the assessment design itself rather than as a downstream implementation detail. Attendees at the poster will be able to inspect the per-institution differences directly and to consider what an empirical calibration workflow might look like in their own assessment context.

Several limitations constrain these conclusions. All reported comparisons are in-sample: the "best" configuration per model-institution pair is selected by lowest RMSE on the same calibration set used for evaluation, introducing optimistic selection bias. The magnitude of the best–worst gap should therefore be read as an upper bound, and the findings as preliminary evidence rather than deployment-ready conclusions; held-out validation on the reserved test set ($n = 611$) is needed to establish a de-biased estimate. The calibration set comprises approximately 50 essays per institution, yielding η^2 estimates with wide confidence intervals (Table 2); the qualitative pattern of model-specificity is more robust than any individual percentage. Interaction effects between prompt dimensions were tested and found to be non-significant, but with only 8 residual degrees of freedom the test has limited power, and the per-dimension attributions should be treated as approximate. The findings are limited to three models from three providers evaluated at a single point in time, and to undergraduate psychology essays marked under UK conventions; whether the model-specificity pattern extends to other disciplines, marking scales, or model generations warrants further investigation. These limitations notwithstanding, the core practical implication appears clear: prompt configuration for LLM-based scoring may be better treated as an empirical calibration problem than as an authoring decision.

ABSTRACT

Writing is an essential skill across grade levels and disciplines. However instructors face critical challenges in providing constructive real-time feedback due to high workloads. While AI services may offer scalable writing support, institutional data privacy and costs remain significant barriers to widespread adoption. This study evaluates the efficacy of small open-source LLMs ($\leq$ 8B parameters) in generating rubric-aligned pedagogical feedback for student essays. Using the PERSUADE corpus (n=25,996), we benchmark small open-source LLMs(SLMs) including Mistral, Gemma, Phi, and LLaMA against proprietary baselines. Our results indicate that these models achieve 68–78% of proprietary performance in feedback quality. We conclude that SLMs represent a viable foundation for scalable, privacy-preserving essay instruction.

Keywords

Automated Writing Evaluation, Large Language Models, Open Source AI, Feedback Quality, Data Privacy.

1. INTRODUCTION

The integration of Artificial Intelligence in education, specifically in **Automated Writing Instruction (AWI) [12]**, offers a potentially transformative solution to the growing crisis in literacy education. Currently, K-12 settings face a dual challenge: declining student writing skills [13] and significant, widespread teacher shortages [36]. This environment has exacerbated a critical "feedback gap," where the demand for personalized, iterative guidance far outpaces the capacity of human educators to provide it.

Researchers have demonstrated that proprietary AI services such as GPT-4 [24] and Claude Sonnet [6] possess the interactive capabilities required to address these complex pedagogical tasks [2]. However, the adoption of these models is often precluded by high operational costs, reliance on external infrastructure, and legitimate data privacy concerns. Consequently, there is an urgent need for SLMs that can serve as private, resource-efficient engines for AWI, capable of providing high-order structural and content feedback at scale.

Within the domain of AWI, generating rubric-aligned feedback for argumentative essays remains a significant challenge. To be effective, models must transcend surface-level linguistic corrections and engage with the "argumentative core" of a text. We evaluate several SLMs such as Mistral, Gemma, Phi, and LLaMA on feedback generation and lead extraction using the PERSUADE corpus. Traditionally, assessing pedagogical feedback requires expert human evaluation, a process that is subjective, time-consuming, and difficult to scale. To mitigate this, we utilize GPT-4o as an automated judge, benchmarking these models against proprietary baselines such as GPT-4 and Claude 3.5 Sonnet (Sonnet 3.5) across four dimensions: specificity, constructiveness, tone, and actionability. Beyond proxy measurements, our study explores how lead extraction provides an additional performance signal for feedback quality when human-gold standards are unavailable. By analyzing the relationship between structural discourse detection accuracy and GPT-4o's feedback quality signal, we investigate whether these SLMs can bridge the feedback gap, successfully replicating the multi-dimensional guidance typically provided by human educators. While SLMs vary in tone and constructiveness, they demonstrate competitive performance in actionability. We further discuss enhancing these capabilities via LoRA [17] and ORPO [15] fine-tuning. This study addresses two primary research questions:

- **RQ1:** How effectively can SLMs replicate the feedback quality of proprietary models across key rubric dimensions?
- **RQ2:** To what extent does a model's accuracy in identifying the "argumentative core" (lead extraction) predict the quality of its generated feedback?

2. RELATED WORK

To address this pedagogical crisis, we must reconcile the reasoning capabilities of LLMs with the constraints of privacy-preserving, local deployment. Below, we review the evolution of language modeling and the current methodologies for Automated Writing Instruction (AWI) that define this research space

Proprietary vs. SLMs: While proprietary models like GPT-4

and Sonnet 3.5 set the state-of-the-art for reasoning and dialogue [25, 5], their adoption in K-12 is limited by high costs and data privacy risks [9]. This has catalyzed research into SLMs such as Llama-3, Mistral, Gemma, and Phi-3 [35, 19, 11, 14]. Optimization techniques like Quantization and Low-Rank Adaptation (LoRA) [16] further enable these models to match proprietary performance on domain-specific tasks while maintaining local, private deployment.

Automated Writing Instruction (AWI): AWI has transitioned from shallow, feature-based scoring (e.g., e-rater [7]) to deep generative tutoring [20, 31]. Effective AWI relies on *argument mining* the segmentation of discourse elements like leads, claims, and evidence [30, 21]. While compact models can achieve near-GPT-4 accuracy in discourse classification [27], their capacity to translate this structural detection into high-order pedagogical feedback remains an active area of investigation.

Evaluating Feedback Quality: Pedagogical feedback is multidimensional, requiring assessment across specificity, tone, and actionability [32]. Given the subjectivity and cost of human expert grading and recent work utilizes Large-Model Judges (e.g., G-Eval [22]). We utilize GPT-4 as a reference signal. We treat this as a reasonable baseline while remaining cautious regarding its direct generalization to pedagogical feedback tasks.

Despite progress in discourse classification, the pedagogical reliability of SLMs remains unproven. This study bridges this gap by evaluating a diverse roster of SLMs using the PERSUADE corpus. We investigate lead extraction as a structural proxy for feedback utility measured by specificity, constructiveness, tone, and actionability benchmarked against a GPT-4o reference judge. Isolating lead extraction provides a clean baseline for structural awareness, as effective hooks are strong predictors of essay coherence [10], while avoiding the confounding complexities of multi-span relational tasks [29].

3. METHODS

In this section, we describe the experimental workflow, which integrates model selection and prompt engineering with an evaluation framework.

3.1 Dataset and Model Selection

We utilize the PERSUADE (Persuasive Essays for Rating, Selecting, and Understanding Argumentative Discourse) corpus ($n = 25,996$) [10]. This dataset is particularly suited for our study as it contains student writing across multiple prompts and genres, with each essay featuring a gold-standard *Lead*, the foundational "hook" or thesis providing the ground truth for our structural extraction tasks. The corpus represents a diverse range of student proficiencies (Grades 6–12), as detailed in Table 1. We benchmark a roster of SLMs against proprietary baselines to evaluate the trade-offs between computational efficiency and feedback performance with model specifications outlined in Table 2.

3.2 Prompt Design:

Our pipeline utilized three distinct zero-shot prompt architectures. For *Lead Extraction*, we employed a strict *verbatim constraint*, instructing models to transcribe the exact introductory string without paraphrasing or error correction to ensure metrics reflected architectural alignment. For *Generative Feedback*, we utilized a *Role-Context-Task* framework, anchoring models as expert tutors and providing PERSUADE 2.0 rubric definitions to standardize formative output. Finally, for *Feedback Scoring*, the GPT-4o judge evaluated the student essays and generated feedback using granular Likert-scale rubrics (1–5) detailed in Section 3.3.

Table 1: PERSUADE 2.0 Corpus

Category	Details / Value
Total Essays (N)	25,996
Sample Size (n)	1,000 (Randomly Sampled)
Unique Prompts	15 (e.g., Electoral College)
Grade Levels	6–12 (Middle/High School)
Avg. Length	350–500 words
Elements	Lead, Position, Claim, Counterclaim, Rebuttal, Evidence, Conclusion

3.3 Evaluation Framework

To standardize the automated assessment, the GPT-4o judge applied a 1–5 Likert scale across four pedagogical dimensions developed in consultation with writing instructors. These definitions, detailed below, prioritize revision utility and student motivation:

Specificity: Measures the transition from vague, boilerplate phrases (Score 1) to explicit referencing or quoting of the student's unique text (Score 5).

Constructiveness: Evaluates whether the model moves beyond binary signaling (Score 1) to provide a developmental roadmap explaining the rhetorical "why" behind suggestions (Score 5).

Tone: Assesses the shift from punitive or clinical language (Score 1) to an encouraging, "growth mindset" voice (Score 5).

Actionability: Quantifies the presence of concrete next steps; a Score 5 requires a clear "revision roadmap" with at least two feasible, immediate tasks.

To measure structural identification(lead extraction), we employed two metrics: **SBERT Cosine Similarity** [28] for semantic overlap, and **BLEU** (Bilingual Evaluation Understudy) [26] to measure n-gram precision between the extracted leads and the ground truth. Overall, the reported values for both extraction metrics and feedback quality represent the mean scores calculated across the sampled essays.

3.4 Lead Extraction as a proxy

We prioritize lead extraction as the primary proxy for feedback quality indicator because the lead serves as a critical rhetorical "anchor," requiring the model to establish global context from the outset. While we plan to investigate broader discourse elements such as evidence and counterclaims in future work, the ability to craft an introductory "hook" that previews an argumentative trajectory is a hallmark of rhetorical control [8]; thus, its successful extraction

signals a model's capacity to integrate long-range dependencies and align initial framing with a global thesis.

4. RESULTS

We evaluated model performance across essays using an NVIDIA A100 GPU. The evaluation focused on two primary dimensions: **Lead Extraction** (RQ1), assessing structural identification, and **Feedback Quality** (RQ2), assessing pedagogical utility.

As shown in Table 3, SLMs specifically **LLaMA-3.1-8B** and **Phi-4-mini** surpassed GPT-4o in extraction accuracy. This suggests that structural identification is a mature capability for models $\geq$4B parameters. In the feedback phase, Phi-4-mini proved the most capable SLM, achieving $\sim$68% of the actionability scores recorded by Claude Sonnet.

While SLMs demonstrated high structural accuracy, Table 4 highlights a disparity in feedback substance. SLMs often offer correct but generic advice compared to the targeted revision steps provided by Sonnet 3.5. Furthermore, Phi models occasionally repeated student text verbatim, suggesting that while 8B models are adequate for extraction, tonal nuance and creative synthesis require further tuning.

Notably, we found a correlation (p=0.71) between lead extraction accuracy and feedback generation quality. This suggests that a model's ability to identify lead components can be an indicator of its overall proficiency in providing helpful feedback on argumentative essays such as [10].

5. DISCUSSION

This study demonstrates that compact SLMs represent a viable foundation for scalable, privacy-preserving writing instruction, achieving functional adequacy by matching $\sim$70% of proprietary model performance. While our findings underscore the viability of these models, the observed performance disparities present two critical imperatives for future research.

First, consistent with established correlations between parameter scale and the reasoning capabilities necessary for nuanced feedback [23], our analysis showed a sharp decline when moving from 4-billion to 2-billion parameters. Consequently, future work must investigate whether high-quality training data (synthetic or organic) and specialized instruction tuning (e.g., via LoRA [16] [37]) can offset these parameter deficits to preserve pedagogical efficacy on smaller hardware.

Second, as shown in Table 3, a clear performance hierarchy emerges: LLaMA-3.1-8B and Phi-4-mini dominate the open-source cohort in Lead Extraction (0.87) and Actionability (3.37), respectively, while Gemma-2B represents a performance floor with a collapse in extraction precision (0.22 Cosine). These disparities, contextualized by Table 2, raise critical questions regarding the interplay between architectural "thinness" and pedagogical utility; specifically, it remains to be determined whether the transition from Multi-Query Attention (MQA) [4] and shallow layer depths to Grouped-Query Attention (GQA) [3] and 32-layer profiles is the primary driver of a model's ability to sustain long-range dependencies in argumentative text. While SLMs nearly match proprietary benchmarks in Tone, the persistent "Actionability Gap" suggests that structural awareness alone may not suffice for complex instruction, necessitating further research into whether the observed floor in Gemma-2B is a consequence of its specific attention bottleneck or if parameter density remains the ultimate ceiling for replicating human-level revision roadmaps. Furthermore, does the 8k context window adequate for the PERSUADE corpus constrain holistic feedback for the longer, multi-document assignments prevalent in higher education?

6. LIMITATIONS

The SLMs performance reflects zero-shot capabilities rather than the upper bounds achievable through further prompt engineering and domain-specific fine-tuning. Despite the promising performance of SLMs, several constraints qualify these findings. First, our evaluation relies on the PERSUADE corpus, which consists primarily of argumentative essays from middle and high school students. Consequently, further research is required to evaluate these models across other genres such as narrative or expository writing and within university-level academic discourse to ensure the generalizability of our findings. Second, while GPT-4o serves as a functional proxy for human judgment, its efficacy must be validated in authentic classroom settings for inherit proprietary biases that favor "polished" prose, potentially overlooking subtle pedagogical nuances.

7. CONCLUSION

In conclusion, while SLMs demonstrate significant potential for providing scalable and private writing instruction, their deployment requires targeted research into architecture, datasets, and specialized fine-tuning. By bridging the performance gap between compact models and larger proprietary counterparts, we can develop accessible, high-fidelity tools that provide expert-level pedagogical support. Ultimately, these models offer a viable path toward mitigating instructor workloads while ensuring high-quality, private writing instruction is accessible at scale.

ABSTRACT

When a bilingual second-grader describes a triangle as "pizza" on a geometry assessment, current AI tutoring systems face a classification dilemma: is this a conceptual error, or evidence of a student using everyday vocabulary (Basic Interpersonal Communicative Skills) because they lack the formal mathematical register (Cognitive Academic Language Proficiency)? No existing educational AI system separates mathematical conceptual understanding from second-language processing at the individual response level. We present CL-KT-X, a neuro-symbolic diagnostic engine that performs cross-lingual knowledge tracing through a three-layer architecture: deterministic linguistic fingerprinting, EXTRACT-NORMALIZE-COMPARE algorithmic prompting, and a Truth-First classification router. In validating CL-KT-X, we document a previously unnamed phenomenon—the *AI Whisperer Effect*—in which architecturally similar local LLMs require model-specific prompt engineering to achieve comparable diagnostic accuracy. Validated on 74 authentic responses from bilingual Title I classrooms across two mathematical domains, the system achieves 98.6% classification accuracy with zero Truth-First violations. This work crosses linguistic, disciplinary, and contextual borders to address equity in AI-assisted mathematics assessment for the 5.3 million emergent bilingual students in U.S. schools.

Keywords

Knowledge Tracing, Cross-Lingual Assessment, Algorithmic Prompting, Bilingual Education, Educational Equity

1. INTRODUCTION

Emergent bilingual students—those developing proficiency in English while maintaining their native language—navigate two linguistic systems simultaneously when responding to mathematical assessments. A student who writes "pizza" for triangle is not demonstrating a geometric misconception; she is applying a Basic Interpersonal Communicative Skills (BICS) analogy because she has not yet acquired the Cognitive Academic Language Proficiency (CALP) term in her second language [4, 5]. Current AI-powered assessment systems cannot make this distinction, systematically misclassifying linguistically mediated responses as conceptual errors.

The consequences are measurable. More than 5.3 million emergent bilingual students attend U.S. public schools, with over one million in Grades 2–3 [8]. English learners are identified for special education at elevated rates in unadjusted models (OR $\approx$ 2.56 at Grade 3), attenuating under full covariate adjustment [9]; among those referred for reading concerns, most did not qualify for the referred disability on evaluation (34 of 44) [10]. Traditional knowledge tracing approaches model mastery as a single latent variable [3, 11, 6], capturing *whether* a student errs but not *why*. They cannot distinguish "doesn't understand circles" from "understands circles but calls them *círculos*."

We present CL-KT-X (Cross-Lingual Knowledge Tracing with Explainable Feedback), a neuro-symbolic diagnostic engine that separates L1 conceptual understanding from L2 language processing by routing student responses through a deterministic pipeline where only the extraction phase is LLM-dependent. Our contributions are threefold:

1. A **neuro-symbolic architecture** for cross-lingual mathematical diagnosis, combining deterministic linguistic fingerprinting with constrained LLM extraction and an invariant Truth-First classification router.
2. **Authentic validation** on 74 classroom responses from bilingual Title I students across two mathematical domains, achieving 98.6% classification accuracy—eliminating reliance on synthetic test batteries.
3. Documentation of the **AI Whisperer Effect**, a previously unnamed phenomenon in which architecturally similar sub-10B parameter LLMs exhibit divergent diagnostic accuracy under identical algorithmic prompts.

This work responds directly to the EDM 2026 theme of *Educational Data Mining Across Borders*. CL-KT-X crosses three borders simultaneously: the *language border* between Spanish and English student responses, the *discipline border* integrating computational linguistics with mathematics education and knowledge tracing, and the *context border*

between everyday communicative register (BICS) and academic assessment vocabulary (CALP).

2. RELATED WORK

Knowledge tracing has evolved from Bayesian Knowledge Tracing [3] through deep neural architectures [11, 13] to context-aware attentive models [6]. These advances have substantially improved prediction of student performance trajectories, yet they share a structural limitation: knowledge is modeled as a single latent construct. A student transitioning from "unlearned" to "learned" on a fractions concept may have always understood the mathematics but lacked the second-language vocabulary to express it. To the authors' knowledge, no existing knowledge tracing model separates conceptual from linguistic knowledge states.

Bilingual education research has long recognized the challenge of disentangling language proficiency from content mastery [1, 12]. Cummins' BICS/CALP framework [4, 5] establishes that conversational fluency (BICS) is acquired in 1–3 years, while academic register (CALP) requires 5–7 years. In mathematics, a student may operate at CALP level in Spanish but BICS level in English, producing responses that appear mathematically incorrect under monolingual evaluation. Accommodations such as translated assessments improve validity [12] but do not address real-time diagnostic classification at the individual response level.

The application of large language models to educational assessment has expanded rapidly [7], yet these systems treat language as a transparent medium rather than a variable that interacts with domain knowledge. The emerging field of algorithmic prompting—providing LLMs with step-by-step computational procedures rather than task descriptions—has demonstrated gains in mathematical reasoning [14] but has not been applied to cross-lingual diagnostic contexts. Furthermore, the assumption that prompt engineering transfers uniformly across models within the same parameter class has only recently begun to be examined. Our work addresses both gaps: we apply algorithmic prompting to cross-lingual diagnosis and document empirically that this assumption does not hold.

3. SYSTEM ARCHITECTURE

CL-KT-X employs a three-layer neuro-symbolic architecture. **Layer 1: Linguistic Fingerprint**—a deterministic module that detects Spanish-origin tokens, phonetic approximations (e.g., "tree" for *three*), and BICS vocabulary using curated lookup tables, requiring no LLM invocation. **Layer 2: ENC Algorithmic Prompting**—the LLM performs only EXTRACT (identifying the student's mathematical claim from a free-text response); NORMALIZE, COMPARE, and CLASSIFY execute deterministically in Python using curated BICS-to-CALP equivalence tables. **Layer 3: Truth-First Router**—an architectural invariant ensuring that mathematically incorrect answers *always* resolve to Conceptual_Gap regardless of detected language artifacts.

Algorithm 1 presents the ENC pipeline. The critical design decision is the separation of EXTRACT (LLM-dependent) from NORMALIZE-COMPARE-CLASSIFY (deterministic). This constrains LLM hallucination to the extraction phase, where it is intercepted by the normalizer's curated lookup tables before classification. The Truth-First Router (line 5) cannot be overridden by language detection.

Algorithm 1 EXTRACT-NORMALIZE-COMPARE Pipeline

Require: r (student response), a (expected answer), d (domain)
Ensure: $c \in \{\text{Conceptual_Gap}, \text{Linguistic_Gap}, \text{Correct}\}$

1: $F \leftarrow \text{LinguisticFingerprint}(r)$ ▷ Deterministic: L1 tokens, phonetics, BICS
2: $e \leftarrow \text{LLM_Extract}(r, d)$ ▷ LLM-dependent: "What shape is described?"
3: $n \leftarrow \text{Normalize}(e, \textit{BICS_CALP_Table})$ ▷ Deterministic: e.g., "pizza" → "triangle"
4: $m \leftarrow \text{Compare}(n, a)$ ▷ Deterministic: semantic equivalence
5: **if** r is mathematically incorrect **then**
6: **return** Conceptual_Gap ▷ **Truth-First invariant**
7: **else if** $F.\textit{has_L1_artifacts}$ **and** $m = \text{TRUE}$ **then**
8: **return** Linguistic_Gap
9: **else if** $m = \text{TRUE}$ **then**
10: **return** Correct
11: **end if**

4. METHODOLOGY

4.1 Corpus

The validation corpus comprises 74 authentic student responses collected from bilingual Title I elementary classrooms in the [REDACTED] metropolitan area. Two mathematical domains are represented: Geometry (37 vectors) and Fractions (37 vectors). All responses are unedited, raw classroom artifacts produced by emergent bilingual students (Grades 2–5) during regular instructional assessment. No synthetic augmentation or researcher-generated examples were used. To the authors' knowledge, this represents the first authentic cross-lingual mathematical response dataset used to validate an AI diagnostic system.

Response collection involved de-identified archival artifacts from routine instructional assessment conducted by the Co-PI in their capacity as a certified classroom educator. No personally identifiable information was collected or retained. Student data was handled under FERPA-compliant local processing protocols.

4.2 Dual-Review Protocol

Each response underwent a dual-review classification protocol. First, an independent pedagogical classification by a certified bilingual education specialist (15 years of classroom experience, campus-level teaching recognition) assigned ground-truth labels (Conceptual_Gap, Linguistic_Gap, or Correct) based on professional assessment of the student's mathematical understanding and language use. Second, blind CL-KT-X engine processing produced classifications with no access to the specialist's labels. Discrepancies were reconciled by a certified bilingual educator serving as Principal Investigator. The PI override rate of 17.1% across all domains documents productive human-AI collaboration in the diagnostic loop—evidence that the system augments rather than replaces expert judgment.

Gold-standard labels for the expanded corpus ($N = 97$, math and geometry domains, SO-15-01 stratum filter applied) were established through joint expert consensus scor-

Table 1: Domain certification results on authentic classroom responses. All vectors are unedited student artifacts from bilingual Title I classrooms, classified via dual-review protocol.

Domain	Vectors	Correct	Accuracy	TF Viol.
Geometry	37	36	97.3%	0
Fractions	37	37	100.0%	0
Combined	**74**	**73**	**98.6%**	**0**

ing by the two authors, both certified bilingual educators with extensive TELPAS calibration experience (TEA official records). Labels were assigned collaboratively through expert deliberation rather than independent blind annotation; this joint consensus process constitutes the gold standard against which CL-KT-X is evaluated. Human-system agreement between this gold standard and CL-KT-X output was assessed using Cohen's κ, yielding $\kappa = 0.8785$ (95% CI [0.790, 0.954], BCa bootstrap, $B = 20{,}000$ iterations), exceeding the $\kappa \geq 0.80$ threshold established as the minimum for reliable NLP annotation [2]. This metric reflects agreement between the joint expert consensus gold standard and the system output; it is not a measure of independent inter-annotator agreement. Independent multi-annotator validation is identified as future work (Section 6.2).

4.3 Model Configuration

CL-KT-X was validated using three local LLMs deployed via Ollama: Llama 3 (8B parameters), Mistral 7B-Instruct, and Qwen 2.5 (7B parameters). All models received identical ENC algorithmic prompts. Local deployment ensures FERPA compliance—no student data leaves the school network. The deliberate selection of architecturally similar sub-10B parameter models serves a dual purpose: it tests whether the ENC framework enables diagnostic accuracy with resource-constrained models deployable in Title I school infrastructure, and it creates the controlled conditions under which the AI Whisperer Effect becomes observable.

5. RESULTS

5.1 Domain Certification

Table 1 presents classification accuracy across two mathematical domains. Geometry achieved 36/37 correct classifications (97.3%) and Fractions achieved 37/37 (100.0%), yielding a combined accuracy of 73/74 (98.6%) across all authenticated vectors. Zero Truth-First violations were recorded across both domains—no mathematically incorrect response was classified as a linguistic gap. The single geometry misclassification involved a multi-claim response where the LLM extraction phase truncated a semantically complex student utterance, a known boundary condition documented as the BICS Semantic Ceiling.

5.2 The AI Whisperer Effect

Table 2 reveals a previously undocumented phenomenon we term the *AI Whisperer Effect*. Across three architecturally similar local LLMs and three adversarial prompting strategies applied to the same $N = 97$ corpus, unweighted κ ranges from -0.0047 (Llama 3, Role Injection) to $+0.2449$ (Mistral, Role Injection)—a spread of more than 0.25 κ units among models comparable in parameter count (7–8B) and architecture family. No LLM cell exceeds $\kappa = 0.25$ on either metric; all remain far below the XODA baseline of $\kappa = 0.8785$. These models respond differently to identical algorithmic scaffolding, and no prompting strategy rescues performance.

Table 2: Gate 9 adversarial evaluation ($N = 97$ per cell, parse_rate$= 1.000$). Exact%: exact match. Adj%: within ± 1 tier (adjacent agreement; not accuracy). κ_{uw}: unweighted Cohen's κ. CI: 95% BCa ($B = 10{,}000$, seed 42). GTP-2=Role Inject; GTP-3=CoT Override; GTP-4=Lang. Switch. †CL-KT-X evaluated in-sample; LLMs evaluated zero-shot. Δ should be interpreted under this condition asymmetry.

Model	Strat.	Ex%	κ_{uw}	95% CI
Llama 3	GTP-2	27.8	-0.005	$[-0.106,\ 0.110]$
Llama 3	GTP-3	20.6	$+0.015$	$[-0.063,\ 0.102]$
Llama 3	GTP-4	26.8	$+0.002$	$[-0.093,\ 0.109]$
Mistral 7B	GTP-2	52.6	$+0.245$	$[0.146,\ 0.369]$
Mistral 7B	GTP-3	39.2	$+0.173$	$[0.074,\ 0.287]$
Mistral 7B	GTP-4	45.4	$+0.126$	$[0.049,\ 0.236]$
Qwen 2.5	GTP-2	52.6	$+0.244$	$[0.138,\ 0.370]$
Qwen 2.5	GTP-3	26.8	$+0.036$	$[-0.070,\ 0.151]$
Qwen 2.5	GTP-4	40.2	$+0.077$	$[-0.056,\ 0.219]$
CL-KT-X†	—	—	**0.8785**	**[0.790, 0.954]**

This finding challenges the assumption that prompt engineering transfers across models within the same parameter class. We hypothesize that the AI Whisperer Effect emerges from differences in instruction-tuning procedures and tokenizer behavior that manifest specifically under the constrained extraction tasks required by cross-lingual diagnosis. The practical implication is significant: deployed educational AI systems using local LLMs require empirical validation of prompt–model compatibility, not architectural assumption.

5.3 Prompt Evolution

The 98.6% combined accuracy with Llama 3 represents a substantial improvement over the 64.9% baseline achieved with the initial prompt version on the same fractions corpus—a progression spanning four major revisions. Notably, an intermediate revision that improved geometry performance caused a regression in fractions accuracy (94.6% → 83.8%), demonstrating that prompt modifications for one mathematical domain can cascade into regressions in another. This *Prompt Example Cascade* is a subtype of the AI Whisperer Effect under investigation in ongoing work.

6. DISCUSSION AND CONCLUSION

6.1 Implications

CL-KT-X demonstrates that cross-lingual knowledge tracing is achievable with resource-constrained local LLMs when the system architecture separates LLM-dependent extraction from deterministic classification. The neuro-symbolic design constrains hallucination risk to a single pipeline stage, making the system's reasoning transparent and auditable—properties essential for high-stakes educational assessment.

The Truth-First Router provides a hard guarantee that no mathematically incorrect response can be misclassified as a language barrier, an invariant that purely neural approaches cannot offer.

The AI Whisperer Effect has implications beyond bilingual education. Any deployed system using local LLMs for student response analysis must account for model-specific prompt sensitivity, even among architecturally similar models. This finding reframes what might be dismissed as "brittleness" as a systematic property of small-model behavior under algorithmic prompting constraints.

6.2 Limitations

Five limitations warrant explicit disclosure. First, CL-KT-X was evaluated against the same 97-item corpus used during system development; this in-sample evaluation means the $\kappa = 0.8785$ figure reflects performance under favorable conditions. The LLMs reported in Table 2 were evaluated zero-shot on the same items, creating an asymmetric comparison (in-sample system versus zero-shot baselines). This asymmetry does not invalidate the comparison—both XODA and the LLMs were scored against the same joint expert consensus gold standard using the same metric—but readers should interpret the Δ advantage accordingly. Independent held-out evaluation on unseen data is the primary objective of ongoing work. Second, gold-standard labels were established through joint expert consensus by the two co-authors; as the authors also developed the system being evaluated, an inherent conflict of interest exists. Independent blind annotation by researchers unaffiliated with system development is identified as a necessary condition for broader validity claims and is planned as the next annotation phase. Third, the validation corpus of 74 vectors across two domains, while authentic, is modest in scale; expansion to additional domains (decimals, word problems) and grade levels is in progress. Fourth, the AI Whisperer Effect has been documented across three models and four prompting strategies; broader surveys are needed to characterize the phenomenon fully. Fifth, the current system targets mathematics; whether the ENC framework generalizes to other content areas (e.g., science vocabulary) remains an open question. These represent active research directions rather than architectural constraints.

6.3 Conclusion

This work makes three contributions to educational data mining across borders: a neuro-symbolic architecture for cross-lingual mathematical diagnosis, an authentic validation protocol grounded in bilingual classroom practice, and the identification of the AI Whisperer Effect as a systematic phenomenon in local LLM deployment for educational assessment. Future work includes domain expansion, longitudinal tracking of student knowledge states across assessments, and systematic investigation of the Prompt Example Cascade. CL-KT-X represents a step toward equitable AI-assisted assessment for the 5.3 million emergent bilingual students whose mathematical understanding currently risks being lost in translation.

7. ACKNOWLEDGMENTS

The authors thank the bilingual Title I classroom educators whose instructional practice produced the authentic response artifacts that ground this research. This work is conducted independently by mar&mar ideas products & more, LLC / QuizMyBrainz.

Simulating Programming Traces and State Spaces for Hint Generation

Jesper Dannath

Bielefeld University
bpaassen@techfak.uni-bielefeld.de

ABSTRACT

Data-driven approaches for next-step hint generation in programming suffer from a cold-start problem, meaning that high-quality hints depend on the presence of sufficiently similar student data – which is missing whenever systems are deployed for new programming tasks. Pre-trained large language models (LLMs) circumvent this cold-start problem. However, because LLMs are not fine-tuned for specific tasks, their hints may contain irrelevant information, or reveal the solution outright. Further, LLMs require substantial resources and long response times to generate hints. We propose to combine the strengths of both LLMs and data-driven approaches: We harness the flexibility of LLMs to generate diverse artificial student solutions. Then we compare methods for simulating student programming traces, thus addressing the cold-start problem. Importantly, we synthesize traces subtractively, starting from the solution and recursively removing elements, thus achieving a fine-grained simulation of programming progress. From simulated traces, state spaces can be constructed and used to generate hints. Our results show that the simulated state spaces are similar to the ones obtained from real student data. Additionally, student step prediction using a simulated state space leads to comparable results to step prediction via prompting LLMs – while being substantially more efficient at inference time.

Keywords

programming traces, state space simulation, programming hints, intelligent tutoring systems

1. INTRODUCTION

A lack of resources for personalized tutoring remains a major challenge in introductory programming education [12]. Personalized hints provided by intelligent tutoring systems during programming tasks can complement teaching and enhance the quality of programming education [23]. AI tools are already used by many programming students for assistance on homework tasks [28]. However, these tools can lead to over-reliance and an offloading of cognitive effort, potentially hindering learning [26]. According to Vygotsgyan pedagogy and scaffolding theory, teachers should give only enough assistance to students such that they can proceed on the given task by themselves [7]. Next step hints provide a framework for applying scaffolding theory in AI-assisted learning environments [11]. Large Language Models (LLMs) can be used to generate next step hints in programming effectively [21] but consume significant resources and even when prompted not to, they tend to give the students access to multiple steps or even complete solutions [1]. On the other hand, data-driven methods for generating next step hints usually rely on a pool of pre-existing student and hint data [11]. However, these approaches suffer from the cold-start problem, meaning that they rely on the availability of interaction data or teacher-generated data.

In this work, we aim to bridge the gap between LLM-driven and data-driven hint-generation by simulating an initial set of trace data for data-driven algorithms. We utilize LLMs to generate diverse verified solutions across a variety of approaches and solution-complexity levels. We then employ our subtractive trace-simulation approach, meaning that we start from a (student-generated or LLM-synthesized) correct solution to a task and recursively remove elements until the empty program is reached. By analysing the state spaces that arise from such simulated programming traces, we aim to answer the main research question whether and under which circumstances using simulated interaction data is a feasible approach for programming hint-generation? We also address the question whether the simulated student traces resemble real student data and might be useful as synthetic training data or for testing purposes. We approach these questions with the following core contributions:

1. Novel methods for subtractively simulating programming traces from correct solutions including a fine-tuned LLM for reversing programming steps in Python.
2. An experimental comparison of simulated versus real state spaces.
3. An investigation on the feasibility of applying the simulated traces for downstream hint generation methods.

2. RELATED WORK

Data-driven hint generation methods often rely on state spaces to represent student behavior [18]. A state space

consists of a directed graph where the nodes are student states and the edges represent student steps between states. Each state is hereby closely related to the current student program (snapshot). Often, some form of canonicalization or clustering is applied to group slightly different program snapshots and thus achieve a more robust and concise state space [19, 18, 17]. Next step hints can be generated from state spaces using a two-step approach: First, the student's current snapshot is matched to an existing state in the state space [17]. Second, an algorithm selects one of the outgoing states as a prediction of the next state – which is then provided as a hint [11]. One example of such an algorithm would be the hint factory, which employs a Markov Decision Process to select a next step that leads to a correct solution on a short path [18].

For a long time, simulating student behavior has been used to model and understand student learning [24, 22]. The focus used to be on modeling student's cognitive properties and predict the outcome of student task attempts [27]. In programming, it is very difficult to obtain fine-grained simulation data of student interactions, since the solution spaces for programming tasks are vast (combinatorially exploding with the size of the program). Today, LLMs offer a new paradigm for generating synthetic data in domains with vast solution spaces [13]. Previous work has utilized in-context learning and fine-tuning LLMs to generate realistic student attempts based on a reference trace by the same student [14]. Even more recent work is using LLM-Agents that employ reasoning-LLMs and tool-calling in order to derive each student step [6, 27]. In particular, CoderAgent includes memory-retrieval and update steps as well as planning and reflection steps yielding higher Accuracy compared to previous methods [27]. The resulting traces can be used in downstream tasks such as learner modeling and training hint generation models taking student knowledge and learning into account. Our proposed subtractive approach sacrifices some versatility, but circumvents the complexity of predicting a next state by simulating backwards, such that a model merely has to decide which part of a program was likely added last, requiring substantially fewer resources.

3. METHOD

We are approaching programming hint generation through the use of simulated state spaces which are aggregated from simulated programming traces. We can view a programming trace as a sequence of program snapshots s_t for $t \in \{1, ..., T\}$. For simulating traces, we need to predict the mapping from s_t to s_{t+1}, which is a difficult problem, as the number of possible line steps is vast. Additionally, the mapping needs to be applied recursively to obtain a complete trace with no guarantee that a correct solution will be reached (and risk of error accumulation). On the other hand, if s_{t+1} is given, estimating s_t is significantly easier in many cases, as usually we just have to decide which line to delete. Therefore, our strategy is to construct an approximate mapping f s.t. $f(s_{t+1}) \approx s_t$. This mapping can be applied recursively to yield a reverse trace $s_T, s_{T-1}, \ldots, s_0$ with $s_0 = \varepsilon$, the empty program. We call this a *subtractive* approach.

A state space for a task is traditionally build from a range of example attempts, aggregated on a specific step-granularity (programming traces). As outlined above, scaffolding theory provides a pedagogically inspired ideal for step-granularity. A previous user-study indicates that the line-level might be a good approximation of a reasonable scaffolding step-granularity for introductory python tasks [3]. Therefore, we build state spaces from simulated programming traces such that transitioning between nodes is equivalent to applying one line-level change to the current user program (see Figure 3). Below we describe the simulation-method in further detail.

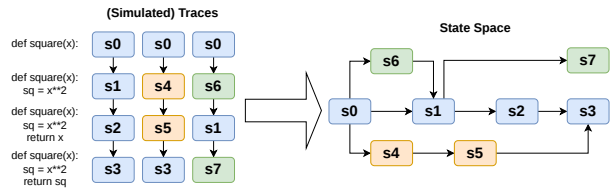

Figure 1: Method: simulated line-based programming traces are aggregated to state spaces

3.1 Generating solutions

For generating diverse correct solutions to a task we are applying a two-step prompting approach. We ask a reasoning-LLM (Qwen3.5-397B) to generate a list of 15 approaches to the task described in one or two sentences. Then, in a second step, a LLM (Qwen3-235B) is prompted without reasoning to implement different versions of each of the approaches. Specifically we first ask the LLM to provide a baseline implementation for a student with medium python skill. Then we repeatedly ask the LLM to make a simpler or a more complex version of it, until the quota (61 solutions total per task) is reached. If a generated solutions wasn't unique after up to four retries, we reduced the quota by one and proceeded to the next attempt. The complete prompt and all other prompts as well as the code for all analysis and supplementary analysis are accessible in our GitLab repository[1].

3.2 Deleting from a random block (RBLL)

We evaluate a programmatic approach for step subtraction which is to simply remove the last line from a random control block. To achieve this, we use the Python abstract syntax tree (AST)-module to list all control structures and obtain the lines which their respective block spans (note that blocks can be nested). Then, we sample one random control block (uniform probability) and delete its last line as well as other lines that might need to be deleted to retain a correct syntax. We call this method RBLL (Random Block Last Line; speak rebel). Note that correct syntax is needed to analyze the block structure of Python code. Hence, some Python-specific mechanisms are imposed to ensure that RBLL never deletes lines in ways that would break the syntax (accounting for multi-line statements, except blocks, inserting pass statements for empty blocks, resolving try blocks if their except is deleted). While this code-processing procedure is specific to Python, the reasoning of first standardizing the syntax, then reversing a step and then fixing a few edge cases of breaking syntax can be applied to other imperative

[1] `https://gitlab.ub.uni-bielefeld.de/publications-ag-kml/step-simulation`

programming languages as well. We do not claim that our approach addresses all possible edge-cases in Python. However, we could not observe any simulation error for RBLL throughout our experiments.

3.3 Prompting LLMs for reversed steps

We compare RBLL with a step-subtraction method based on pretrained LLMs. We utilize an iteratively developed prompt format which is structured into system prompt, context and query. The prompt context contains three elements, starting with a description of how the outputted reversed line steps should be structured. Then, we give the model the correct solution it is deducting steps from. Finally, we embed the first three snapshots and the three most recent snapshots in the model context. In the query we then continue to prompt the model to delete a single line from the current snapshot. Alternatively, we sometimes prompt the model to introduce an error or a misconception into one existing line of the current snapshot. We sample the query such that the model is asked to introduce errors or misconceptions 30% of the time. We did find that this value yields a significant increase in trace diversity while maintaining plausibility. Generally, this method relies on the LLM to branch off into different directions on repeated simulation runs, while RBLL explicitly employs random branching. The complete prompt is available in GitLab. Since LLMs will sometimes fail to produce a reverse step, we are validating the success of the step reversion. When the LLM was unsuccessful (i.e., leaving code unchanged, manipulating more than a single line, or breaking the syntax), we fall back to RBLL.

3.4 Fine-tuning LLMs for reversed steps

Finding that in many cases the LLM was incapable of reversing a line step correctly (see Section 4.2), we concluded fine-tuning might be a viable strategy to improve performance. We used the described prompting format to create a dataset of real reverse traces. In addition to our dataset (Section 4), we used a second keystroke-level dataset from Utah State University (2019) for additional training examples [5]. Then we employed supervised fine-tuning utilising unsloth [2] with the real reverse steps as a target. 50% of the tasks of each of both datasets (20 tasks in total) were selected randomly for training, resulting in 16465 training examples. We trained a 16-bit LoRA [8] with rank 128 for one epoch (lr 1e-4) on a single A40 GPU. The model was inferenced in 8-bit. We used Qwen3-8B [25] as a base model without reasoning traces or thinking mode. We reference the fine-tuned model as Qwen3-8B-SR (SR for Step Reversion).

4. EXPERIMENTS

We evaluate the state space simulations on a real-world dataset. The dataset was collected at a Mid-European university and consists of programming traces from 29 Python tasks recorded via an intelligent tutoring system [4]. In total, 209 students donated 1400 programming traces across Python Introduction sessions between 2023 to 2025. From these traces, which are recorded on a keystroke level, 7370 Line steps could be inferred. After randomly selecting 50% of tasks for fine-tuning, 14 tasks remained for computing the below experiments. For obtaining line steps, We also remove all complete detours from student traces. "Complete" refers to the kind of detours that lead to the exact same state later on. The tasks are about basic python concepts and NumPy as well as Data Mining methods. For evaluation, we used pretrained LLMs of different sizes from the Qwen3 model family, namely Qwen3-8B, Qwen3-coder-30B-A3B (short Qwen3-30b) and Qwen3-235B [25]. Additionally, we utilized RBLL as a baseline and Qwen3-8B-SR as our own fine-tuned model based on Qwen3-8B (Section 3.4). The 8B models were both used in 8-bit quantization on a single NVIDIA RTX 5060 Ti with 16GB of VRAM. Qwen3-30B and Qwen3-235B were used in 16-bit quantization using the scaleway-API. We use three traces per solution for the simulation of state spaces.

Table 1: Fallback rates for step reversion by LLM

Qwen3-8B	Qwen3-30B	Qwen3-235B	Qwen3-8B-sr
76.9%	74.1%	55.0%	35.8%

4.1 Metrics

We compare state spaces of the real student traces (from tasks in the test set) with simulated state spaces. All metrics are based on a matching of states between the real and the simulated state spaces. For matching, we canonicalize all programs using their AST, normalizing variable, function, and class names, and standardizing strings (programmatically formatted parts of strings are kept). To compare states, our metrics are *precision*, meaning the fraction of states in the simulated state space that also occur in the real state space, and *recall*, meaning the fraction of states in the real state space that also occur in the simulated state space. We also report *recall-5*, where we relax the state matching and allow up to five tokens edit-distance (e.g. single function call with one argument; NLTK wordPunctTokenizer). Recall-5 aims to yield a more realistic estimate of a classroom-setting, where one would usually allow relaxed matching to be able to deliver hints to more students. To compare steps in the state space (i.e. edges from one state to another), we search for matches of real states in the simulated state space and compute the number of the available outgoing edges of these matches (0 if the real state does not exist in the simulated state space). We call this metric *average outgoing score*. The outgoing score aims to estimate how many candidate hints we can expect for a randomly selected state (without accounting for state likelihood). All metrics are averaged across tasks.

4.2 Fallback-rates

We found that, in many cases, the pretrained LLMs were not able to follow the prompt of deleting a single line. Instead, the LLMs often returned the exact same snapshot as before, edited multiple lines, or added lines to the current snapshot. On occasions where the LLM fails to reverse a line-step, we simply fallback to RBLL. Throughout all traces simulated for the experiments in this paper, we observe that failure rates decrease with model size, with 76.9% for the Qwen3-8B and 55% for Qwen3-235B (Table 1). Still, fine-tuning is even more effective than model size with merely 35.8% failure rate for the fine-tuned Qwen3-8B-SR.

4.3 Simulation based on existing solutions

In order to evaluate the step-reversion performance in isolation, we examine the performance of the simulation meth-

Table 2: Mean and SD of state space metrics

Method	Precision	Recall	Recall-5	Outgoing
RBLL	**.43 (.19)**	.29 (.09)	.52 (.16)	.46 (.14)
Qwen3-8B	.38 (.15)	.32 (.08)	.55 (.15)	.56 (.16)
Qwen3-30B	.32 (.13)	.31 (.1)	.55 (.17)	.61 (.19)

Qwen3-8B-SR	.31 (.14)	**.33 (.09)**	.57 (.16)	.63 (.15)

Table 3: Mean and SD of state space metrics for AI-generated solutions

Method	Precision	Recall	Recall-5	Outgoing
RBLL	**.06 (.05)**	.1 (.06)	.31 (.17)	.36 (.21)
Qwen3-8B	.05 (.03)	.11 (.07)	.3 (.14)	.47 (.31)
Qwen3-30B	.05 (.03)	.11 (.07)	.31 (.16)	.5 (.31)
Qwen3-235B	.03 (.02)	**.12 (.07)**	.32 (.17)	**.67 (.43)**
Qwen3-8B-SR	.05 (.05)	.11 (.07)	.29 (.13)	.53 (.36)

ods for recovering state spaces from corresponding real student solutions (Table 2). The results show that, while the control-block based simulation method has the highest precision (.43), it is slightly outperformed by the LLM-based simulation methods on recall and recall-5. In terms of outgoing score, the LLM-based methods outperform the programmatic method by a larger margin, with the Qwen3-235B performing best (.75). For the use-case of synthetic trace-dataset generation for testing or model training, one would have to decide between using RBLL for maximum precision or using the LLM-based approach for more variability and slightly improved recall. Also, while being sufficient on our introductory dataset, the performance of all methods might decrease for longer tasks (See Section 5 and Appendix A).

4.4 Simulation with generated solutions

In many scenarios such as introducing a completely new task, it is reasonable to assume that little to no correct solutions to the task are available. In this section, we investigate how well we can recover real state spaces using only LLM-generated solutions to tasks. LLM-generated solutions are verified using unit tests (therefore, two tasks without unit tests had to be excluded). Table 3 shows the metrics based on up to 61 generated solutions per task (A task might have fewer as described in Section 3.1). In fact, the number of unique solutions that could be generated per task varies between 10 and 61 with a mean of 50.0. The relative performance between the different methods remains similar compared to using the real student solutions: RBLL achieves highest precision, LLMs better recall and more variability. For all methods, overall performance is lower compared to having real student solutions available. Interestingly, the outgoing metric degrades only slightly, whereas precision and recall decrease by a factor of 3. Recall-5 remains more stable between the two scenarios decreasing only by approximately 1/3. We expect that an increased number of generated solutions will generally lead to a higher number of recovered states. In further experiments we can observe that the recall indeed increases for all methods up to 61 generated solutions but the increase diminishes significantly (Figure 2).

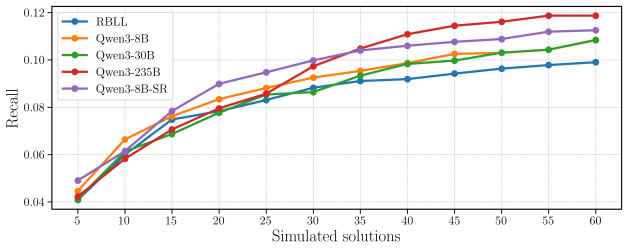

Figure 2: Avg. Outgoing states by number of generated solutions

Table 4: Comparing direct-LLM and state space based step prediction

Method	Tree-edit dist.	chrF	Acc	Acc-5
direct-LLM (8B)	**6.88**	0.76	**0.2**	**0.43**

Sim 235B	7.37	0.76	0.06	0.32
Sim 8B-SR	7.55	**0.77**	0.07	0.33

4.5 Predicting steps

Deriving next step hints using simulated state spaces is not a trivial task. First, a student's new state needs to be matched against an existing state in the simulated state space. We do so by using the closest state according to tree edit distance (TED) on AST [15]. To select a next-step hint we consider the successor of the matched state in the simulated state space closest to the student's state (in terms of TED). If the successor differs in exactly one line from the student's state, this is defined as the next-step hint. Otherwise, we compute the line edit between the matched state and the successor and apply them to the student state, inspired by [10]. If this does not yield correct syntax, we attempt syntax repair by fixing indentation-levels; and if this does not succeed, we predict the successor directly (even if it differs by more than one line). As a baseline, we compare with an LLM prompted to predict the next line step. The prompt contains information on the expected format and step-granularity (line-steps) as well as the task description and current student step and is also available in the linked repository.

Since step prediction is a different task compared to the above evaluations, we employ different metrics. In particular, we report the TED to the actual next step of a student (lower is better), the character-level F-score (chrF; higher is better), which has been shown to align well with human assessment on code generation tasks [16], and the accuracy, meaning the rate of exact matches after canonicalization (higher is better). We also report Accuracy-5, where we mark a prediction as correct based on a relaxed matching up to an token edit-distance of 5 (similar to recall-5). Table 4 shows the results for predicting the next student step on the test-dataset. Among the simulation-based step predictors, RBLL performs best in terms of accuracy and TED. The LLM next step hints perform best in terms of accuracy but are slightly outperformed in terms of chrF. TED is comparable between RBLL simulation and LLMs.

5. CONCLUSIONS

In this work, we investigated the potential of simulating programming traces and state spaces using a subtractive approach based on LLMs and/or programmatic line removal. Such simulation has two major purposes: creating synthetic datasets and providing data for generating next step hints. Our experiments confirm that we can recover real intermediate student states if realistic solutions are available. The recall and precision vary by the employed simulation method: random block last line (RBLL) provides generally higher precision compared to LLMs; and larger LLMs generally achieve lower precision but higher average number of matched outgoing states. This is likely explained by larger LLMs generating more diverse programming traces. Throughout all experiments, the fine-tuned LLM Qwen3-8B-SR performs mostly on par with the much larger 235B model while also retaining a bit more precision. Additionally, the fine-tuned model has a much lower fallback rate, indicating that the task of removing lines from existing code is beyond the scope of the model's pre-training procedure. Using the simulated state spaces for step prediction shows that the LLM-based approaches do not have a benefit compared to RBLL. Given that RBLL is also much more efficient, it is currently the most advisable method for next step hint generation with simulated state spaces.

We also believe that the potential of the selection in state spaces is not fully realized in this work yet, as we didn't investigate more advanced methods of predicting steps within the simulated state spaces. Future work could investigate this and might also find ways to take advantage of the more diverse traces that LLM-based step simulation produces. Also, we did not investigate the effect of combining the simulated state spaces with student or teacher-provided trace data, as might be the case in real-world deployment. Some caution is advised for applying the presented methods for more complex tasks since our dataset only consists of easy introductory python tasks. Our supplementary experiments show decreased performance for state space reconstruction with real solutions on the Utah State keystroke-level programming dataset from 2019 [5], which consists of print statement heavy longer tasks like turtle tasks or CLI based games (see Appendix A). These tasks are considerably longer compared to the ones in our own dataset, but unfortunately lack unit tests and therefore could not be tested for state space reconstruction with LLM-generated solutions and step prediction. Generally, there is a lack of openly available line level or sub-line level python-trace datasets that could be used for evaluating the performance of our method for a larger variety of tasks [9].

Future work should also investigate whether the generated hints from simulated state spaces are effective in a pedagogical sense. This could also be supported by additional effort for personalizing the retrieved simulated states to the students current snapshot, like proposed in [20]. Finally, the large difference in performance between Table 2 and Table 3 suggest that future approaches might be able to improve the quality of simulated state spaces by focusing on the generation of more realistic student solutions. Still, RBLL provides a cheap and effective baseline for future work on simulated state spaces.

ABSTRACT

Characterizing pilot behavior during takeoff is a prerequisite for enabling adaptive interventions in aviation Intelligent Tutoring Systems (ITS). Traditional High-Gain/Low-Gain dichotomies are insufficient to capture the behavioral diversity required for fine-grained learner modeling. This paper presents an unsupervised learning pipeline applied to multivariate time-series data collected from 12 pilots performing A320 takeoffs in X-Plane, resulting in a dataset of 112 rotation sequences. Four temporal clustering methods are evaluated during the rotation phase (S6): G-WVDTW, Temporal-DEC, BiLSTM Autoencoder, and Transformer. The two best-performing methods are subsequently validated on the ground roll (S5) and initial climb (S7) phases. On S6, the BiLSTM suggests five algorithmically-derived behavioral groupings extending beyond the binary paradigm, while the Transformer yields a duration-based separation. Cross-phase validation further indicates that rotation phase is the only segment that provides sufficiently rich and exploitable behavioral diversity for learner profiling, supporting a phase-specific rather than phase-agnostic approach to takeoff profiling.

Keywords

pilot behavioral profiling, temporal clustering, intelligent tutoring systems, BiLSTM autoencoder, transformer, flight simulator

1. INTRODUCTION

Intelligent Tutoring Systems (ITS) for aviation training require fine-grained learner models to provide personalized feedback. However, existing characterizations of pilot control behavior are still largely based on the traditional High-Gain/Low-Gain dichotomy [8]. This binary framework, originally derived from linear control theory, is insufficient to represent behavioral diversity observed in real flight data. Although the takeoff phase represents only about 2% of total flight time, it accounts for roughly 13% of fatal accidents worldwide [2], making it a priority phase for adaptive training interventions.

Prior work on data-driven pilot profiling has explored clustering of flight recorder data for anomaly detection [7] and non-parametric classification of pilot styles [5]. More directly relevant to ITS, Tato et al. [11, 12] demonstrated that unsupervised methods can extract behavioral profiles from simulator data to support adaptive coaching. However, these studies were limited to one or two clustering methods and did not systematically compare deep temporal architectures, nor evaluate the sensitivity of profile extraction to takeoff phase selection.

This paper addresses these gaps with three methodological contributions: (1) a systematic comparison of four temporal clustering paradigms on 112 A320 rotation sequences from 12 pilots with varying expertise; (2) a cross-phase validation on the ground roll (S5) and initial climb (S7) confirming that behavioral diversity is phase-dependent; (3) an analysis of the inductive biases of BiLSTM and Transformer autoencoders, with a discussion of their respective relevance for future learner modeling in ITS. By bridging temporal machine learning, human factors in aviation, and adaptive educational systems, this work contributes to the interdisciplinary foundations of data-driven learner modeling.

2. DATA AND PREPROCESSING

2.1 Experimental Context

Data were collected using the X-Plane desktop flight simulator configured for an Airbus A320 under standard conditions. Twelve pilots across three expertise levels (5 experts, 3 licensed, 4 novices) performed multiple takeoffs, yielding 115 sequences for the ground roll (S5), 112 for the rotation (S6), and 89 for the initial climb (S7) after quality filtering. Input variables were selected per phase to reflect the degrees of freedom available to the pilot, ranging from 4 variables for the highly constrained rotation phase (S6) to 12 for the ground roll (S5) and 13 for the initial climb (S7).

2.2 Preprocessing Pipeline

For the rotation phase (S6), sequence lengths range from 18 to 81 timesteps (mean = 35.4, std = 10.3). Min-Max normalization to $[0, 1]$ was applied to the training set. Variable-length sequences were zero-padded to the per-phase maxi-

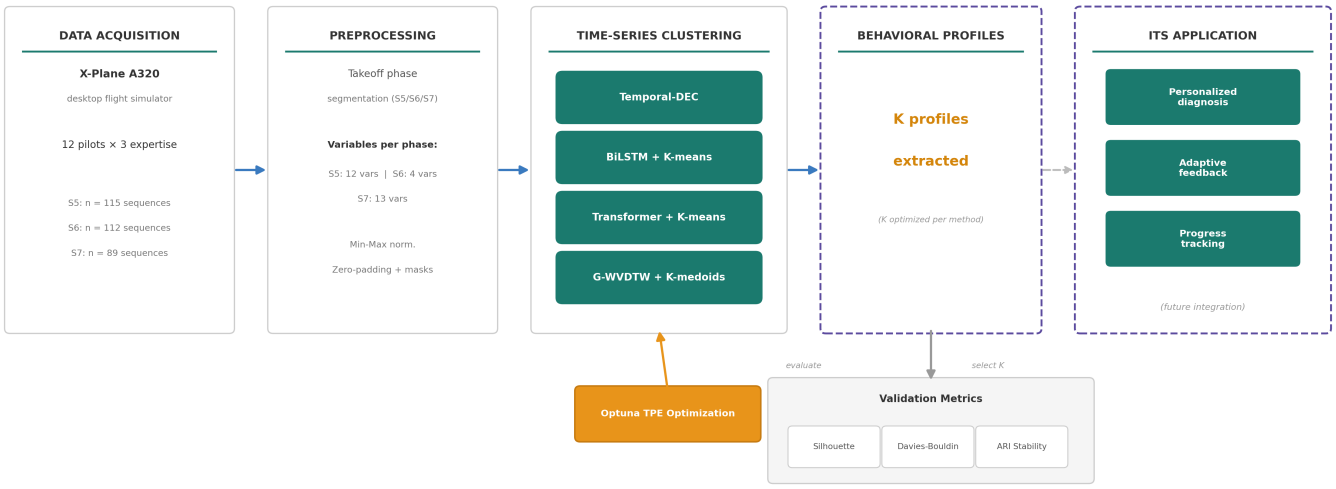

Figure 1: Methodology pipeline. Flight simulator data undergoes phase-specific preprocessing and temporal clustering via four methods. The three deep methods are optimized with Optuna [1]. The optimal K is selected using internal clustering metrics. Resulting profiles constitute a foundation for future ITS integration.

mum length ($T_{\max} = 81$ for S6) with binary masks to prevent gradient contributions from padded timesteps. The dataset was split 80/20 stratified by pilot identity (seed = 42) to avoid data leakage across sequences from the same pilot.

2.3 Evaluation Metrics

In the absence of ground-truth behavioral labels, clustering quality is assessed through three internal metrics and one stability measure. The **Silhouette score** [6] $S \in [-1, 1]$ measures the ratio of intra-cluster cohesion to inter-cluster separation; values above 0.5 indicate reasonable structure. The **Davies-Bouldin index** (DB) [4] penalizes clusters that are dispersed or poorly separated; lower is better, with DB < 1.0 considered satisfactory. The **Adjusted Rand Index** (ARI) measures assignment consistency across 50 independent runs with random initializations; ARI ≥ 0.8 indicates high reproducibility. The optimal number of clusters K is selected by maximizing the Silhouette score over $K \in \{2, \ldots, 7\}$.

These internal metrics assess the geometric quality of the partitions in latent space. They do not, by themselves, establish that the discovered groupings are educationally meaningful or instructionally actionable; such validation requires future expert review and integration into an ITS prototype.

3. METHODS

Four temporal clustering methods are evaluated, spanning three paradigms: distance-based, end-to-end deep, and modular deep. We use the term *cluster* for algorithmically-derived groupings and *profile* for their behavioral interpretation.

3.1 G-WVDTW + K-medoids

A distance-based approach using variance-weighted Dynamic Time Warping [3] to compute pairwise sequence dissimilarities across variables, with weights inversely proportional to per-variable variance. K-medoids clustering is then applied on the resulting $n \times n$ distance matrix. K-medoids was preferred over hierarchical or spectral alternatives for its native compatibility with arbitrary precomputed distance matrices, its robustness to outliers, and the interpretability of medoids as actual representative sequences — a property useful for downstream domain expert review.

3.2 Temporal-DEC

An end-to-end deep clustering framework adapting the Deep Embedded Clustering objective [16] to time series via a BiLSTM encoder. Representation learning and cluster assignment are jointly optimized by minimizing a combined reconstruction and KL-divergence loss.

3.3 BiLSTM Autoencoder + K-means

A modular pipeline separating representation learning from clustering [10]. A bidirectional LSTM autoencoder with temporal attention compresses each sequence into a fixed-size latent vector; K-means is then applied in the latent space. The bidirectional architecture captures both anticipatory and reactive control patterns.

3.4 Transformer + K-means

A modular pipeline replacing the recurrent encoder with a Transformer architecture [15] using sinusoidal positional encoding. The encoder projects input sequences through multi-head self-attention blocks into a latent vector; K-means is applied in latent space. Hyperparameters for the three deep methods were optimized with Optuna [1] (30 trials) using a composite objective balancing ARI stability, Silhouette, and Davies-Bouldin.

4. RESULTS

4.1 Rotation Phase (S6)

Table 1 reports clustering performance across the four methods on the 112 rotation sequences. Modular deep approaches outperform both G-WVDTW and Temporal-DEC on all metrics. G-WVDTW yields a weak Silhouette (0.383) and insufficient stability (ARI = 0.866). Temporal-DEC

achieves intermediate results but remains below modular approaches in cluster separation. Following the interpretation scale of [6], BiLSTM ($S = 0.608$) and Transformer ($S = 0.647$) both fall in the "reasonable structure" range (0.51–0.70).

Table 1: Clustering performance on the rotation phase (S6, $n = 112$).

Method	K	Sil.↑	DB↓	ARI
G-WVDTW + K-medoids	2	0.383	0.990	0.866
Temporal-DEC	3	0.530	0.562	1.000
BiLSTM + K-means	5	0.608	0.452	0.998
Transformer + K-means	2	0.647	0.469	1.000

The BiLSTM Silhouette is maximized at $K = 2$; however, $K = 5$ is retained as the optimal compromise: it maintains a reasonable Silhouette ($S = 0.608$) while achieving the lowest Davies-Bouldin index across all tested values of K (DB = 0.452), indicating compact and well-separated clusters. This $K = 5$ solution suggests five algorithmically-derived behavioral groupings distinguished by dynamic profile shape: a progressive profile (C0, $n = 26$), high-gain inputs (C1, $n = 18$), delayed pitch-up onset (C2, $n = 28$), oscillatory corrections (C3, $n = 23$), and low-gain inputs (C4, $n = 17$). C1 and C4 appear consistent with the High-Gain and Low-Gain categories described in the literature [8]; C0, C2, and C3 suggest intermediate profiles extending beyond the binary paradigm. These labels are assigned post-hoc by visual inspection. A preliminary review by a domain expert confirmed the operational coherence of the five groupings given the available data, though this does not constitute a systematic validation of their educational or instructional significance.

To better characterize the structure of the discovered profiles, we further examined their distribution across pilots and expertise levels. The resulting patterns indicate that the five clusters are shared across the cohort rather than being confined to isolated individuals. The pilot-by-cluster matrix nonetheless reveals mild pilot-specific tendencies in a few clusters, such as a relative concentration of P13 and P7 in C2 and of P11 in C4. These patterns should be interpreted as partial skews within a broader multi-pilot distribution rather than as exclusive cluster ownership, while the expertise distribution confirms that experts and novices contribute to each cluster to varying degrees.

Figure 2 illustrates the dynamic shape differences underlying these post-hoc labels. C1 exhibits the earliest and steepest pitch stick input, producing the fastest pitch rate and the shortest rotation, consistent with high-gain control. C4 displays the opposite pattern: low and delayed stick deflection, slow pitch rate, and the longest rotation, consistent with low-gain control. C2 shows a delayed onset of pitch-up despite eventually reaching comparable angles, while C3 combines an early stick input with intermediate dynamics. C0 occupies an intermediate position with a smooth, progressive trajectory. Across all clusters, vind_kias evolves nearly linearly, confirming that cluster separation is driven by control input dynamics rather than by airspeed differences.

Figures 3 and 4 provide a finer-grained view of how the discovered clusters are distributed across pilots and expertise levels.

The Transformer ($K = 2$, $S = 0.647$, ARI = 1.000) yields a different separation: the two clusters differ primarily in rotation duration rather than dynamic shape, consistent with the expected sensitivity of sinusoidal positional encoding to absolute sequence position. At $K = 5$, the Transformer produces a Silhouette of 0.603 but the five groups remain organized along a continuous duration gradient rather than exhibiting distinct behavioral modes.

Latent space analysis reveals that both architectures produce quasi-2D representations (PCA explains 99.7% and 99.8% of variance for BiLSTM and Transformer respectively), but with fundamentally different geometries: a V-shaped structure with discrete cluster positions for the BiLSTM (separation by dynamic shape), versus a continuous linear gradient for the Transformer (separation by duration). Expertise level does not drive cluster assignment in either model; experts, licensed pilots, and novices are distributed across clusters, though this observation should be interpreted cautiously given the small sample size ($n = 12$ pilots).

4.2 Cross-Phase Validation (S5, S7)

The two best-performing methods (BiLSTM and Transformer) were applied to S5 (115 sequences, 12 variables) and S7 (89 sequences, 13 variables) to assess whether behavioral diversity is phase-dependent. Results are reported in Table 2.

Table 2: Cross-phase validation results (BiLSTM and Transformer).

Segment	Method	K	Sil.↑	DB↓	ARI
S5 (Ground Roll)	BiLSTM	2	0.568	0.629	0.992
	Transformer	2	0.381	1.017	1.000
S7 (Initial Climb)	BiLSTM	2	0.587	0.473	0.989
	Transformer	2	0.760	0.394	1.000

Both methods converge to $K = 2$ on S5 and S7. On S5, the BiLSTM suggests a 76.5%/23.5% split between standard and non-standard pitch input patterns, consistent with the constrained Airbus nose-down procedure between 80 and 100 KIAS. The Transformer yields a weaker separation ($S = 0.381$, DB > 1.0), suggesting the duration-based bias is less discriminative on longer, higher-dimensional sequences. Neither method extracts exploitable stylistic diversity on S5.

On S7, the BiLSTM isolates a single atypical sequence ($n = 1/89$, 98.9% in the nominal cluster), indicating near-uniform behavior consistent with the highly standardized initial climb procedure (flight director, V2 + 10 KIAS, gear and flap retraction). The Transformer achieves the highest Silhouette across all segments ($S = 0.760$), though driven by duration rather than behavioral content: the divergence between the two clusters appears only at the end of longer sequences, with no difference in pilot inputs in the early seconds. This confirms that on standardized phases, the Transformer transitions from behavioral profiling toward sequence-length anomaly detection.

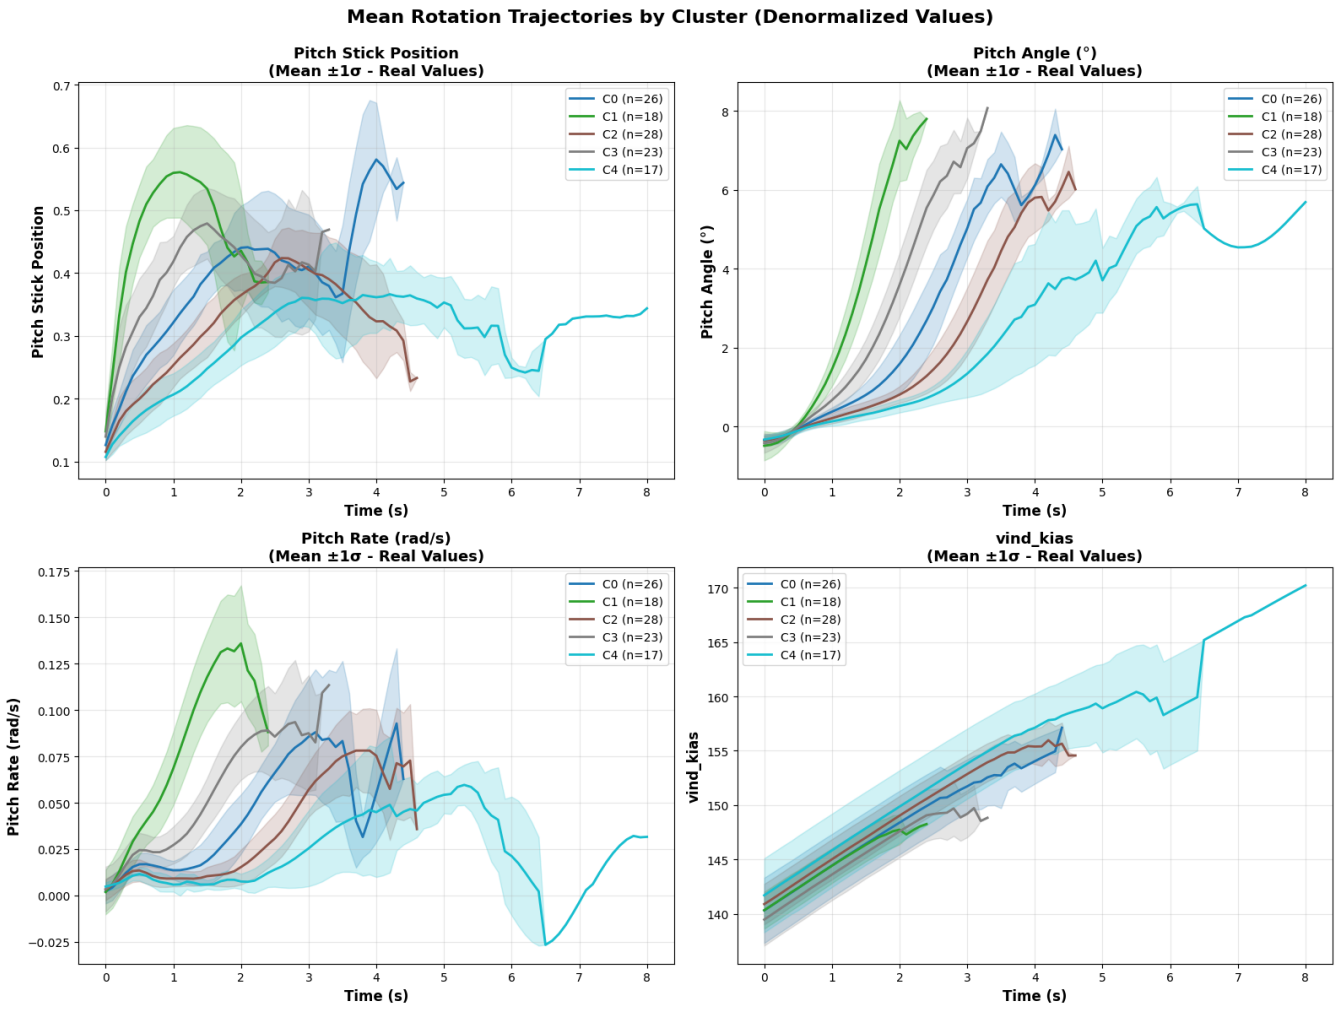

Figure 2: Mean denormalized trajectories ($\pm 1\sigma$) of the four S6 variables across the five BiLSTM clusters.

These results confirm that behavioral diversity is phase-dependent: S5 and S7, being procedurally constrained, yield binary structures without stylistic diversity. Only S6 produces a rich multi-cluster structure ($K = 5$) suitable for further investigation as candidate learner profiles.

5. DISCUSSION

5.1 Inductive Biases and Method Selection

The performance gap between modular deep methods and distance-based or end-to-end approaches suggests that separating representation learning from clustering appears advantageous on this small, high-dimensional flight dataset. G-WVDTW, despite its interpretable distance metric, suffers from the quadratic complexity of pairwise DTW computation and produces coarse separations. Temporal-DEC's joint optimization may cause the clustering objective to interfere with representation quality on limited data.

The contrasting behaviors of BiLSTM and Transformer reveal complementary inductive biases. The BiLSTM accumulates sequential state across timesteps, naturally capturing local dynamic transitions such as pitch rate oscillations and anticipatory stick movements. The Transformer's sinusoidal positional encoding embeds absolute temporal position into every representation, making sequence duration a primary discriminating factor. These biases are not defects but reflect different aspects of pilot behavior: the BiLSTM captures *how* the rotation is performed, while the Transformer captures *how long* it takes.

5.2 Relevance for Learner Modeling in ITS

The five BiLSTM groupings constitute candidate profiles whose operational coherence has been confirmed by a preliminary domain expert review [11, 12], suggesting they capture recognizable piloting patterns rather than statistical artifacts. Operational coherence does not, however, establish educational validity or instructional actionability. If validated against learning outcomes, such profiles could inform differentiated feedback strategies — for instance, exercises targeting smooth control for high-gain pilots or timing drills for delayed-onset patterns. The high clustering stability (ARI = 0.998) is a necessary but not sufficient prerequisite for consistent profile assignment.

The Transformer's duration-based separation, while less

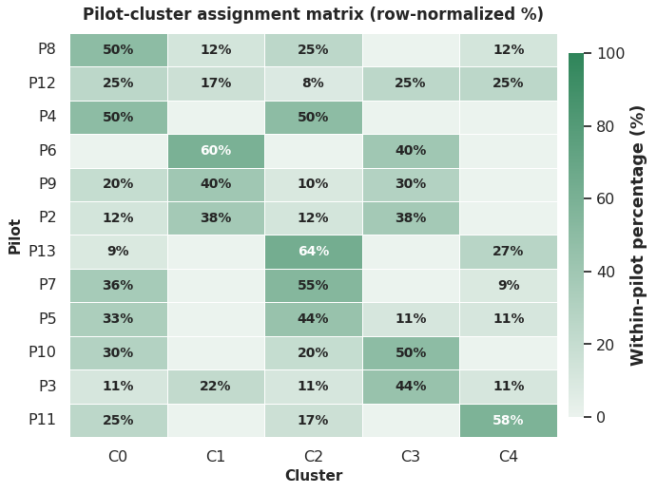

Figure 3: Pilot-by-cluster assignment matrix (row-normalized %).

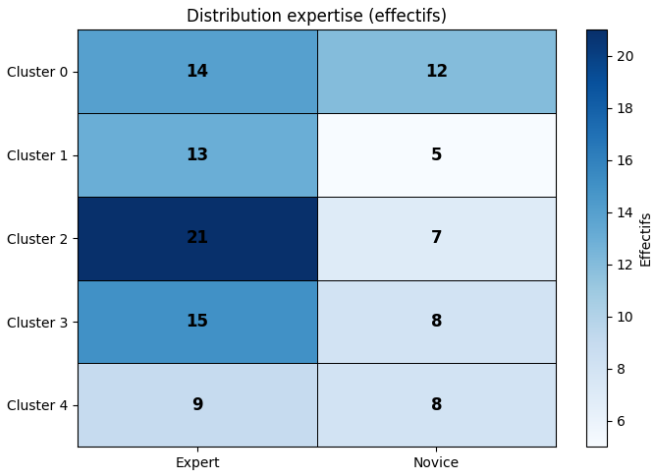

Figure 4: Distribution of cluster assignments by expertise level.

suited to style profiling, could complement the BiLSTM perspective by monitoring rotation efficiency — a metric relevant to procedural compliance assessment.

Overall, this work provides a methodological foundation rather than a validated ITS component. The transition from coherent clusters to educationally actionable profiles requires systematic multi-assessor validation and integration into a tutoring loop with measurable learning outcomes.

5.3 Limitations

Several limitations warrant acknowledgment. First, the dataset comprises 12 pilots and at most 115 sequences, which is sufficient for a proof-of-concept but not for establishing a generalizable taxonomy [9]. Small-sample settings can amplify apparent structure and make estimates optimistic, so the observed patterns should be interpreted as methodological candidates rather than definitive learner categories [13, 14].

Overfitting risk on 112 rotation sequences is mitigated by three design choices: (i) purely reconstructive training without label supervision, (ii) constrained latent dimensionality (8–16 units) tuned via Optuna with dropout and weight decay, and (iii) clustering stability verified across 50 random initializations (ARI $\geq$ 0.99). Latent representations may nonetheless encode pilot-specific idiosyncrasies, making the per-pilot distribution analysis (Figure 3) essential to interpret groupings as shared patterns rather than pilot signatures.

Other limitations include the use of a desktop simulator (simulator fidelity), post-hoc visual labeling validated by a single expert [11, 12], the inability of internal metrics to establish educational meaningfulness, and the restriction to the takeoff phase.

6. CONCLUSION

We presented an unsupervised pipeline for extracting candidate pilot behavioral profiles from multivariate flight simulator data, comparing four temporal clustering methods across three takeoff phases. On the rotation phase (S6), modular deep approaches outperform distance-based and end-to-end methods: the BiLSTM autoencoder suggests five behaviorally distinct groupings extending beyond the binary High-Gain/Low-Gain paradigm [8], while the Transformer yields a complementary duration-based separation. Cross-phase validation confirms that behavioral diversity is phase-dependent: only S6 produces a multi-cluster structure, while S5 and S7 converge to binary splits reflecting procedural constraints.

These results provide a methodological foundation for data-driven learner diagnosis in aviation ITS. The complementarity between BiLSTM (control style) and Transformer (temporal efficiency) perspectives suggests richer learner models combining both. Future work will focus on broader expert validation, larger pilot populations, and integration into an ITS prototype to assess profile-specific feedback effects on learning outcomes.

ABSTRACT

Large language models (LLMs) are increasingly used for estimating item difficulty in educational assessment. However, it remains unclear whether such estimates reflect how learners actually experience difficulty. This study investigates the alignment between LLM-generated difficulty ratings and empirical student performance on basic mathematics tasks. Four widely used LLM-based systems generated difficulty ratings (1-100 scale) for 32 arithmetic items across multiple runs (N = 640 ratings). These were compared with empirical difficulty derived from responses of 770 Indonesian undergraduates using Classical Test Theory (CTT) and Item Response Theory (2PL). Results show moderate rank correlations (Spearman's $\rho = 0.52 - 0.7$), indicating that LLMs capture coarse ordering of item difficulty. However, substantial and systematic misalignment emerges in fraction items. Several items consistently rated as "easy" by LLMs were among the most difficult for students (e.g., only 34.16% correct for $100 \div 12$). We argue that LLMs approximate curricular difficulty—what should be easy based on instructional sequencing—rather than cognitive difficulty driven by learner misconceptions. This leads to systematic underestimation of misconception-driven items, a phenomenon we term the "Easy Trap." These findings highlight a critical limitation of LLM-based difficulty estimation and suggest that relying on such estimates without empirical grounding may introduce bias in assessment design and adaptive systems.

Keywords

Educational Data Mining, Item Response Theory, Adaptive Assessment, Cognitive Modeling, Psychometric Calibration

1. INTRODUCTION

Large language models (LLMs) are rapidly being integrated into educational practice, extending far beyond basic search or item drafting to functions that directly affect assessment—providing feedback, assisting with grading for multiple-choice and open-ended responses, recommending remedial content, generating curriculum-aligned items, and even estimating item difficulty from text alone [5, 8, 19, 27, 29, 35, 38]. While these capabilities promise substantial gains in efficiency, they also introduce crucial measurement risks: LLM-generated judgments often reflect curricular expectations rather than empirical patterns of student performance, potentially leading to mis-calibrated difficulty labels when real learners diverge from what the curriculum prescribes [1, 23].

This risk is becoming salient for so-called "basic" mathematics. Foundational number concepts—arithmetic with whole numbers, integers, fractions, decimals, and exponents — appear early in schooling yet continue to challenge many undergraduates, with well-documented downstream effects on later success in STEM disciplines [4, 16, 21, 33, 36]. Among these domains, fractions are repeatedly identified as a bottleneck skill and a strong predictor of attainment in algebra, statistics, and calculus [14, 15, 21, 30]. Formal instruction in fractions begins in Grade 3, but persistent misconceptions—e.g., whole-number bias, treating numerators and denominators independently, or assuming "division makes smaller"—are widely reported across contexts and often persist into higher education [20, 22]. When LLMs classify such fraction items as "easy" on the grounds that they are introduced early in curricula, their predictions may systematically underestimate actual difficulty for undergraduate learners.

Empirical difficulty can be estimated from student performance using Classical Test Theory (CTT), which defines difficulty as the proportion of students answering correctly (p-value), and Item Response Theory (IRT), which models the interaction between latent ability and item characteristics [9, 12, 15]. Recent studies have explored the use of LLMs to approximate expert judgments of difficulty or to infer IRT parameters from item text [1, 28]; however, findings suggest that surface textual features are weak predictors of latent difficulty compared to empirical response data.

This study evaluates whether LLM-generated difficulty estimates align with empirical undergraduate performance on basic arithmetic items. Beyond measuring alignment, we investigate a systematic source of misprediction: the distinction between curricular difficulty (what is expected to be easy based on instructional progression) and cognitive difficulty (what is actually difficult due to persistent mis-

https://doi.org/10.5281/zenodo.21039732

conceptions). We hypothesize that LLMs primarily encode curricular expectations, leading to systematic underestimation of items that are procedurally simple but conceptually challenging. Using responses from 770 Indonesian undergraduates and difficulty estimates from four LLM systems, we examine where and why these mismatches occur, and what they imply for the use of LLMs in educational assessment.

Research question (**RQ**): *"To what extent do LLM-based difficulty estimates align with empirical student performance on undergraduate basic arithmetic, and how does the disconnect between these measures reveal specific misconception-driven demands that models fail to capture?"*

2. RELATED WORKS

Item difficulty is traditionally measured using Classical Test Theory (CTT) and Item Response Theory (IRT). In the 2-parameter logistic (2PL) IRT model, item difficulty and discrimination parameters enable sample-invariant estimation under standard conditions and support fine-grained diagnostics [12, 15]. Emerging work explores using large language models (LLMs) to approximate expert judgments of difficulty or infer psychometric properties directly from item text [23, 28]. However, evidence suggests that surface textual features are weak predictors of latent difficulty compared to empirical response data, and many approaches rely on simulated responses or proxy indicators rather than real student performance [1].

LLMs are increasingly used to support assessment workflows, including item generation, grading, and feedback [5, 8, 37]. Recent studies have investigated whether LLMs can estimate item difficulty, with promising correlations reported in controlled settings [1, 28]. However, these approaches largely depend on simulated learners or benchmark datasets, leaving open questions about how well LLM-generated difficulty reflects actual student performance, particularly in conceptually demanding domains.

Fractions are widely recognized as a challenging domain in mathematics education, with difficulties persisting into higher education [4, 21]. Prior work shows that fraction understanding predicts later success in algebra and overall mathematical achievement [17, 31]. These difficulties are often driven by persistent misconceptions, such as whole-number bias and incorrect reasoning about operations, which continue to affect even university students [10, 11].

Despite this extensive literature, there is limited empirical data on fraction performance among undergraduates. This gap makes it difficult to assess whether LLM-generated difficulty estimates reflect young adult learner performance or primarily encode curriculum-based expectations. In this study, we combine CTT and 2PL IRT with real response data from 770 Indonesian undergraduates to evaluate the alignment between LLM-generated difficulty estimates and empirical difficulty. By grounding the analysis in observed learner performance, we examine how discrepancies between model predictions and student outcomes reveal the limitations of LLM-based difficulty estimation.

3. METHOD

3.1 Participant

Participants were 770 second-year undergraduate students enrolled during 2020 to 2025 in mandatory mathematics courses at a large public university in Indonesia (79.74% female, 20.26% male; mean age = 19.2 years). All students had completed Indonesia-K13 mathematics curricula through Grade 9 – 12 (before the national shift to the Merdeka Curriculum in 2021). Participation was voluntary, and informed consent was obtained. The study used previously collected data approved for secondary analysis by the university ethics board (Authorization No. 511/In.23/L.1/TL.01/12/2025) and received additional approval from the Human Research Ethics Committee (Project ID: 50488).

3.2 Instrument

3.2.1 BMA Test

The Basic Mathematics Ability (BMA) assessment consisted of 32 multiple-choice items covering arithmetic operations aligned with K13 Grades 3-7 standards. The distribution was as follows: whole number operations (n = 5), integer operations (n = 10), fraction operations (n = 11), decimal operations (n = 4), and exponents/roots (n = 2). Items were drawn from validated Indonesian textbooks (published by the Ministry of Education) and prior validated research [20]. Each item had four response options.

The present analysis focuses on eleven fraction items (Items 3, 11, 20, 23, 25, 27, 28, 29, 30, 31, 32) spanning addition, subtraction, multiplication, division, and magnitude comparison. These eleven items represent all fraction-related items from the 32-item assessment. The test was administered via Google Forms and paper-and-pencil formats in proctored classroom settings (90-minute time limit). Calculators were not permitted to ensure assessment of procedural fluency.

3.2.2 LLM Difficulty Estimation Prompt

Difficulty predictions were obtained from four frontier LLM based AI systems:

1. Claude Sonnet 4.5 (Anthropic, September 2025)
2. Gemini 3 (Google DeepMind, November 2025)
3. ChatGPT 5.2 (OpenAI, GPT-5 series, December 2025)
4. Microsoft Copilot (Powered by GPT-5, December 2025)

For each item, each model was queried independently across four repetitions (N = 4 models × 5 repetitions × 32 items = 640 total difficulty scores). A standardized prompting template was used as illustrated in Figure 1 (detailed outputs are available in the GitHub repository). We evaluated consistency across multiple runs using flip-rate, which measures the proportion of questions where the model produced different answers between runs [13].

3.3 Empirical Difficulty Measures

We calculated the empirical item difficulties using Classical Test Theory (CTT) and 2-parameter logistic (2PL) IRT. These approaches provide complementary perspectives on item difficulty. CTT offers intuitive, sample-dependent difficulty indices based on the proportion of correct responses, whereas IRT estimates latent item difficulty parameters (β) while accounting for differences in student ability levels. The

Prompt for Generate Item Difficulty

You are an expert in mathematics assessment design.
Evaluate the following item:
ITEM: [Full item picture with options]
CONTEXT:

- Target population: Indonesian undergraduate students
- All content taught in elementary school under Indonesian Kurikulum 2013
- Purpose: Evaluate item characteristics and estimate functional difficulty for undergraduate students on a Basic Mathematics Ability (BMA) instrument.
- Item Review: Identification of mathematical topic, domain, targeted skill, and curriculum grade alignment.
- Cognitive Demand: Assessment of skill difficulty, cognitive load, multi-step reasoning, and prerequisite concepts.
- Difficulty Scale: Constrained numerical scale reflecting automatic fluency, basic procedural skill, or basic multi-step reasoning.
- Provide an exact difficulty score (1 - 100 scale):
  1 - 10 = Automatic basic fluency
  11 - 20 = Basic procedural skill
  21 - 30 = Basic multi-step
  31+ = Higher cognitive load
- Justify your rating briefly.

OUTPUT: Structured item-level difficulty table with mathematical topic, domain, prerequisite concepts, multi-step reasoning, and curriculum alignment.

Figure 1: Standardized prompting template that used in all LLMs.

2PL model was selected instead of the 1PL (Rasch) model because preliminary inspection indicated substantial variation in item discrimination across the 32 problems (a range from 0.28 - 1.83, M = 1.20, SD = 0.37). Item spanned all five discrimination categories defined by Baker [2], from very low (n = 2) to very high (n = 2), with the majority falling in the moderate (n = 16) ranges. Although a detailed analysis of discrimination is beyond the scope of this study, this heterogeneity is inconsistent with the equal-discrimination assumption of the 1PL model and motives the use of 2PL. In the 2PL model, difficulty parameter can then be compared directly with LLMs-estimated difficulty [12].

We estimated 2PL IRT model parameters using marginal maximum likelihood (MML) via the mirt package in R [7]. IRT's item difficulty theoretically range from $-\infty$ to $+\infty$, but typically falls between -3 and +3 in practical testing. Values near 0 indicate average difficulty, negative values reflect easier items, and positive values correspond to harder items [2].

To evaluate alignment between LLM-generated difficulty estimates and empirical difficulty measures, we computed Spearman's rank correlation (), Root Mean Squared Error (RMSE) and Mean Absolute Error (MAE). We rated consistency across multiple runs using two different metrics: (a) flip-rate, which measures the proportion of questions where the model produced different answers between runs [13], and (b) intra-class correlation (ICC) calculated using python pingouin package.

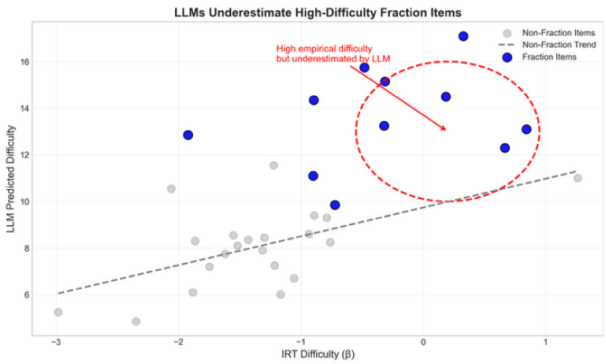

Figure 2: As empirical difficulty increases, LLMs systematically assign lower-than-expected difficulty scores to fraction items.

4. RESULTS

We distinguish between two forms of difficulty throughout the analysis: (1) curricular difficulty, reflected in LLM generated estimates based on procedural and textual features, and (2) cognitive difficulty, reflected in empirical performance shaped by learner misconceptions. We evaluated the alignment between LLM-generated difficulty estimates and empirical difficulty using multiple metrics. Across models (32 arithmetic items), LLM predictions show moderate rank alignment with empirical difficulty (Spearman's $\rho = 0.52 - 0.77$; Table 1), indicating that models capture coarse ordering of item difficulty. Similar patterns were observed for both IRT and CTT measures. However, rank alignment masks substantial discrepancies in absolute difficulty. RMSE and MAE values vary notably across models (Table 1), showing that models with similar correlations differ in their ability to estimate difficulty magnitude. This indicates that correlation alone overstates practical predictive accuracy.

Figure 2 compares LLM-predicted difficulty with empirical IRT difficulty. For CTT, we are using (1 – p) to align the magnitude with other measurements. Non-fraction items follow the expected positive trend, indicating general alignment between model predictions and empirical measures. However, fraction items systematically deviate from this relationship. As empirical difficulty increases ($\beta > 0$), fraction items become much harder for students, but the increase in LLM-predicted difficulty is smaller than expected.

This judgement suggests that LLMs fail to capture sources of cognitive difficulty specific to fraction concepts. Although isolated cases of underestimation appear among non-fraction items, these do not form a consistent pattern. In contrast, the repeated and directional deviation observed for fraction items indicates a domain-specific bias rather than random error (also showed in flip rate at Figure 3). While within-model variance was observed, it did not consistently correspond to prediction error, suggesting that variability alone is not a reliable indicator of misalignment.

Fraction items account for the most severe misalignment between LLM-predicted and empirical difficulty. Table 2 lists the five most underestimated items, all of which were consistently rated as "easy" by LLMs despite empirical failure rates exceeding 66.8%. In the most extreme case, only 34.2%

Table 1: Correlation between individual LLM predictions and empirical difficulty measures

LLM Model	IRT**	CTT**	RMSE (IRT)	MAE (IRT)	Rank
Claude Sonnet 4.5	0.700*	0.776	0.809	0.638	Best rank alignment
Gemini 3 Pro	0.624*	0.737	0.857	0.665	Balanced
ChatGPT 5.2	0.567*	0.716	0.974	0.721	Worst magnitude
Microsoft Copilot	0.515*	0.595*	0.943	0.727	Best magnitude
CTT	0.912*		0.366	0.257	Empirical baseline

*Significant at $\alpha = 0.05$.
**Correlation using Spearman ρ.
For CTT, we use $(1 - p)$ to align the magnitude with other measurements.

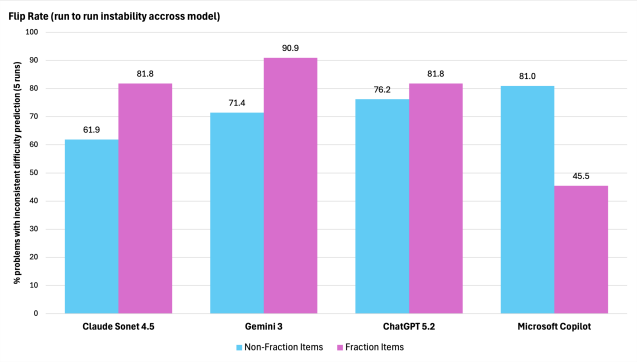

Figure 3: Flip Rate (Run-to-run Instability Across Models).

of students correctly solved division between whole number and fraction (100 12), although it was consistently categorized as a basic procedural task. We refer to this systematic misclassification as the "Easy Trap": items that are procedurally simple but conceptually conflicting are consistently underestimated by LLMs.

Analysis of student response distributions (Table 3) reveals that errors are not random but reflect systematic misconception patterns. Common incorrect responses include "division makes smaller" beliefs, whole-number bias, inappropriate operation selection, and incorrect reasoning about magnitude. These patterns indicate that empirical difficulty is driven primarily by conceptual misunderstandings rather than procedural complexity.

This pattern is further supported by the flip rate analysis shown in Figure 3). Across most models, fraction items produced higher rates of inconsistent difficulty predictions than the overall item set (for 5 runs). Especially for Gemini, which shows almost 91% inconsistency during repetition, which means 10 out of 11 fractions get different difficulty estimation more than 3 times. This suggests that LLM judgments on misconception-driven fraction problems are not only systematically misaligned with empirical student difficulty, but also less stable across repeated evaluations. The consistently higher flip rates for fraction items indicate that conceptually conflicting problems introduce greater uncertainty in LLM difficulty estimation compared to arithmetic items overall.

Taken together, these results suggest that LLM-generated difficulty estimates align more closely with procedural complexity and curricular expectations, but fail to fully capture cognitive difficulty driven by persistent misconceptions.

5. DISCUSSION

Our findings reveal a systematic distinction between curricular and cognitive difficulty in LLM-based estimation. While LLMs achieve moderate rank alignment with empirical measures, they consistently underestimate items whose difficulty is driven by persistent misconceptions. This suggests that LLMs rely primarily on surface-level procedural cues and curricular sequencing, rather than modeling the cognitive processes that shape student performance. As a result, LLM-generated difficulty estimates reflect what should be easy according to instruction, rather than what is actually difficult for learners.

Error analysis (Table 3) provides insight into the cognitive sources of this misalignment. Undergraduates continue to retain foundational misunderstandings typically associated with earlier grades. Common errors—"division makes smaller" reasoning (Item P32), inappropriate operation selection (Item P20), and whole-number overgeneralization (Items P11, P28)—indicate many students lack robust mental models of fractions. These patterns align with established research on fraction difficulty, particularly whole number bias and magnitude understanding [4, 17, 18, 24, 32]. Our study extends this line of work with a higher-education perspective: despite completing 12 years of schooling, many students still lack stable conceptual understanding and frameworks for elementary fraction operations.

Stability analyses reveal that fraction items are vulnerable to run-to-run variability. Figure 3) show high flip-rates meaning that users may receive different difficulty labels for identical items across attempts. This align with argument by Gonzales [13] that GPT-4 family models change their answer on ∼35% of problems in 3 repetitions. This volatility reflects both stochastic generation and inconsistent sensitivity to cognitive features, underscoring the need for response aggregation and uncertainty reporting when difficulty scores inform instructional decisions or assessment design.

These results have direct implications for educators and institutions increasingly relying on LLM-generated items as part of classroom assessment. In Indonesian higher education, classroom practice already uses LLM-generated items to evaluate student understanding [25, 26, 34]. Our findings caution against depending on single difficulty estimates for high-stakes decisions, as our repeated query analyses show that LLMs often produce varying interpretations of identi-

Table 2: Fraction Items with the Largest LLM Underestimation of Empirical Difficulty

Item	LLM's Difficulty Estimation Range				LLM Mean	IRT β	CTT
	Claude Sonnet	Gemini Pro	Chat GPT	Copilot			
P32	13–18	10–15	8–18	6–12	12.30	0.667	0.342
P3	10–18	12–16	6–9	10–16	13.10	0.843	0.384
P11	17–20	18–25	10–18	12–18	17.10	0.328	0.426
P20	10–16	15–18	9–16	9–18	14.50	0.185	0.449
P28	14–16	12–14	9–22	8–13	13.25	-0.319	0.553

Note: LLM difficulty estimates represent the range across five runs for each model. LLM Mean is the average across all models and runs. IRT β is the 2PL difficulty parameter. CTT is the proportion of students answering correctly (p-value). Lower CTT values indicate higher empirical difficulty.

Table 3: Distribution of student responses and dominant misconception patterns for the five most underestimated fraction items

Item	Correct (%)	Common Incorrect Answer Pattern(s)	Misconception Type
P32: $100 \div \frac{1}{2}$	34.2%	50, 100	Operation misinterpretation ("division makes smaller")
P3: Estimate the sum of $\frac{12}{13} + \frac{7}{8}$	38.4%	19, 21	Fraction magnitude misconception
P11: $2\frac{3}{5} + 1\frac{2}{3}$	42.6%	$3\frac{5}{8}$, $3\frac{8}{15}$	Component-wise addition error
P20: $\frac{2}{3} - \frac{3}{5}$	44.9%	$\frac{1}{2}$, $\frac{1}{5}$	Whole-number bias
P28: $\frac{12}{15} \div \frac{4}{15}$	55.3%	$\frac{3}{15}$, $\frac{1}{5}$	Fraction division misconception

Note: Correct (%) shows the proportion of students who answered correctly. Common Incorrect Pattern(s) lists the most frequent wrong answers chosen by students. Misconception Type describes the underlying conceptual error driving the incorrect responses.

cal prompts across users and attempts—instability also documented by Gonzales [13] and Castleman et al. [6] across leading LLMs on mathematics problems. Instead, LLM estimates should be treated as provisional heuristics requiring empirical validation, not ground validated difficulty values. The misalignment between algorithmic and cognitive difficulty means LLMs may systematically misclassify which items will challenge students.

This difficulty misalignment is particularly important for educational data mining applications. In adaptive testing and automated item generation, difficulty estimates play a central role in sequencing content and personalizing learning experiences. When misconception-driven items are systematically rated as easier than they actually are, assessment systems may select inappropriate items, miscalibrate learner ability, and reduce the effectiveness of instructional interventions. These findings suggest that LLM-based assessment systems should be grounded in empirical learner data rather than relying solely on model-generated difficulty estimates. Overall, this study should be interpreted as an exploratory baseline for understanding how LLMs estimate mathematical difficulty in misconception-driven contexts. These results provide an initial foundation for future work on cognitively informed LLM-based assessment systems.

Several limitations should be considered when interpreting these findings. First, this study focuses on fraction arithmetic among Indonesian undergraduate students. Although fractions are well known for misconception-driven errors [3, 17], it remains unclear whether the "Easy Trap" phenomenon also appears in other mathematical domains of undergraduate learning such as algebra, geometry, or calculus. Future studies should examine whether similar patterns emerge across different topics. Second, while the dataset included 770 students, the analysis was based on only 32 arithmetic items, with the clearest evidence of systematic underestimation found in 11 fraction items. A broader evaluation involving more items and mathematical domains would provide stronger evidence regarding the consistency of LLM difficulty misalignment. In addition, the data were collected from a single institution, so further validation across institutions and cultural contexts is needed. Third, our prompting approach was intentionally designed to reflect realistic educational use, where educators ask LLMs to estimate item difficulty without detailed information about student misconceptions or error patterns. Although this mirrors current practice in AI-assisted assessment design, richer prompts that include misconception patterns or cognitive analysis may improve alignment between LLM predictions and empirical difficulty. Future research should investigate whether misconception-informed prompting can reduce this systematic bias.

6. CONCLUSIONS

This study shows that LLM-based difficulty estimation captures the relative ordering of item difficulty but systematically fails to represent cognitive difficulty driven by misconceptions. As a result, fraction items—where performance depends on conceptual understanding rather than procedural complexity—are consistently underestimated. We interpret this as evidence that LLMs encode curricular expectations rather than learner-centered difficulty, leading to a measurable and predictable bias.

Taken together, these findings suggest that while LLMs are promising tools for rapid item prototyping and scalable content generation, their effective use in assessment requires approaches that integrate model efficiency with empirical validation, psychometric calibration, and human expertise. Although this study focuses on fraction arithmetic, this domain provides a well-established testbed for examining persistent misconceptions and cognitive bottlenecks in mathematics learning. The observed misalignment therefore points to broader limitations of LLM-based assessment tools when

applied to conceptually demanding domains.

ABSTRACT

Formative assessment in mathematics should attend not only to answer correctness but also to the procedural evidence embedded in students' problem-solving processes. Evidence-centered design (ECD) offers a principled basis for connecting learner evidence to task design. However, in classroom contexts, teachers face substantial time and cognitive burden when designing formative assessment tasks based on students' evidence. This study presents a preliminary implementation of a task–evidence–task cycle for formative assessment using a large language model (LLM). Using 1,406 solution logs collected from 29 students, the LLM infers required knowledge components (KCs) from students' step-by-step solution logs and constructs diagnostic evidence (e.g., procedural differences, targetable causes, and required KCs). It then uses this evidence to generate two scaffolding tasks for each original task. Expert evaluation showed moderate agreement on the generated KCs and substantial agreement on the appropriateness of the scaffolding tasks. A small follow-up activity with four students further suggested that the generated tasks may help make missing intermediate reasoning steps more visible during re-solving. These findings provide preliminary feasibility evidence for one implemented task–evidence–task cycle, while repeated cyclic use is left for future work.

Evidence-centered Design, Scaffolding Task Generation, Step-by-Step Solution Logs, Large Language Model

1. INTRODUCTION

In mathematics education, formative assessment plays a key role in supporting students' learning throughout the problem-solving process. It should therefore attend not only to the correctness of final answers but also to the processes through which those answers are produced.

Mathematical problem solving involves interpreting problem situations and coordinating multiple cognitive components. Koedinger et al. [7] define these as knowledge components (KCs), or learnable units of knowledge or cognitive function. Because procedural and conceptual knowledge interact and develop together in mathematics learning [13], students' procedural work can be interpreted as evidence of KC use during problem solving. Assessment should therefore move beyond answer correctness to examine process-level evidence in students' work.

Evidence-centered design (ECD) provides a principled framework for making such inferences by specifying relationships among claims, evidence, and tasks [10, 12]. However, many ECD implementations remain largely task-driven: tasks are specified first, and evidence models are used mainly to interpret task outcomes [1]. As a result, the process by which diagnostic evidence informs subsequent task design often remains underspecified or is treated as a black box [5].

To address this gap, this study adopts KCs as an interpretive unit for constructing diagnostic evidence and implements a task–evidence–task cycle in which evidence from students' solution logs informs subsequent task design. Operationalizing such redesign in classrooms is challenging because extracting KCs from student work and redesigning formative tasks require substantial time and cognitive effort from teachers [2]. Although recent studies have explored large language models (LLMs) for analyzing student work or generating assessment-related artifacts [8, 9, 11, 16], most have focused on isolated functions such as task generation, automated scoring, or feedback rather than integrated, evidence-based task redesign [6].

This paper presents a preliminary implementation of an ECD-grounded task–evidence–task cycle for formative assessment. The LLM is used for two related functions: (1) constructing diagnostic evidence from students' solution logs, including inferred KCs, and (2) generating scaffolding tasks based on that evidence. The generated tasks are reviewed by two experts, and their appropriateness and potential educational usefulness are examined.

Accordingly, this study addresses the following research questions (RQs):

RQ1. To what extent can an LLM generate meaningful KC candidates required for problem solving from students' solution logs?

RQ2. To what extent can an LLM generate formative scaffolding tasks based on KCs inferred from students' solution

2. BACKGROUND

2.1 Evidence-Centered Design for Formative Assessment

Evidence-centered design (ECD) frames assessment as a principled approach to making inferences about learning from observable performance [10, 12]. By organizing assessment around claims, evidence, and tasks, ECD emphasizes that validity depends not only on task format or difficulty but also on what evidence is collected from learners' work and how it is interpreted [8].

This perspective is especially relevant to formative assessment, which aims to identify learners' current difficulties and provide targeted support [2]. In ECD-based formative assessment, tasks are not only measurement tools but also means of making learners' thinking visible. When scaffolding is evidence-based, it should respond to procedural bottlenecks, omissions, and error patterns observed in students' actual work rather than rely on fixed hints [15].

Although ECD presupposes an ongoing interplay between evidence and task design [10], its applications have typically proceeded in a forward direction: tasks are defined first, and evidence models are then developed to interpret the resulting performances. In such task-driven implementations, the link between diagnosis and the design of subsequent tasks is often left implicit [1, 5]. Recent LLM-based studies have addressed parts of this broader process, including the analysis of student work and the generation of assessment-related outputs [8, 9, 11, 16]. Most, however, have focused on isolated functions, such as scoring, feedback, or task authoring, rather than on evidence-driven formative task redesign as an integrated process. Moreover, many existing approaches still generate tasks primarily on the basis of predefined learning objectives or answer structures [3], with relatively little work systematically using evidence from students' problem-solving processes to guide subsequent task design.

In this study, we adopt an ECD-grounded cyclic Evidence–Task Design Framework in which evidence derived from student solution logs is translated into subsequent formative scaffolding task design.

2.2 Knowledge Components as Units of Evidence

Knowledge components (KCs) are acquired units of cognitive function or knowledge structure that can be inferred from performance on related tasks [7]. In mathematics, a task typically requires multiple KCs rather than a single one [13]. Accordingly, assessments based only on answer correctness may fail to capture learners' actual difficulties.

Prior work has shown that errors, omissions, and incomplete solution steps can serve as evidence for inferring learners' knowledge states [4]. In this study, KCs are operationally defined as units of knowledge that enable mathematical performance, such as definitions, conditions, meanings, and interpretation rules [7]. KC-related errors or omissions in students' solution processes are interpreted as indicators of learning gaps and used as fine-grained evidence for subsequent scaffolding task design. Recent studies have also explored LLMs as tools for supporting this kind of evidence interpretation and generation process [4, 11, 16].

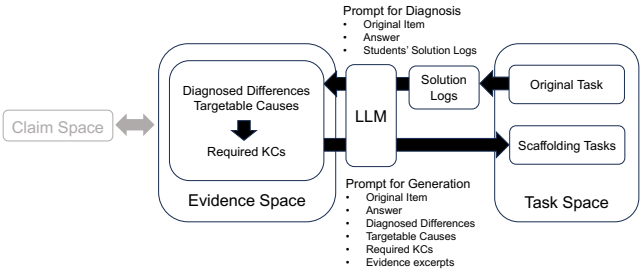

Figure 1: Overview of one implemented task–evidence–task cycle using an LLM.

3. TASK–EVIDENCE–TASK CYCLE

This study presents one implemented task–evidence–task cycle (Figure 1) in which an LLM converts student solution logs into diagnostic evidence and then uses that evidence to design scaffolding tasks. The cycle links a task space to an evidence space through two prompt-based transformations: diagnosis (task space → evidence space) and generation (evidence space → task space). Knowledge components (KCs) function as the shared representational basis across these stages, linking what is inferred from students' work to what is subsequently targeted in scaffolding-task design.

3.1 Prompt Design

We implemented the prompting pipeline in two stages: a diagnosis prompt for constructing evidence from student logs, and a generation prompt for producing scaffolding tasks from the diagnosed evidence.

3.1.1 Prompt from Task Space to Evidence Space

The diagnosis prompt takes as input the original task, the final answer, and students' line-level solution logs. For each task, the logs are grouped into correct and non-correct responses (including incorrect and unfinished responses) based on final-answer correctness. The prompt then asks the LLM to compare the two groups and identify recurring procedural differences, such as omitted conditions, incorrect relational expressions, or points at which solutions stop before completion. Based on these differences, the LLM is prompted to identify targetable causes, that is, aspects of performance that appear to be missing, incomplete, or insufficiently activated and that could plausibly be addressed through instructional support. The prompt also asks the model to infer 10 required KCs associated with those causes and needed to solve the original task. During prompt development, candidate set sizes of 5, 10, and 15 were examined across tasks of different difficulty levels, and 10 was adopted for the present implementation.

To make the diagnosis explicit and traceable, the prompt requires all outputs to be grounded in concrete excerpts from the solution logs, including equations, symbols, and written statements. These excerpts serve as evidence for the identified procedural differences, targetable causes, and related KCs.

3.1.2 Prompt from Evidence Space to Task Space

The generation prompt takes as input the original task, the final answer, the diagnosed procedural differences, the targetable causes, the generated KC candidates, and supporting evidence excerpts from the solution logs. Using these inputs, the LLM generates scaffolding tasks intended to address the diagnosed difficulties revealed in the earlier stage.

The prompt constrains the LLM not to generate tasks that simply rehearse isolated KCs or lead directly to the final answer. Instead, the generated tasks are designed to elicit intermediate products that make students' reasoning visible, such as stating relevant conditions, constructing relational expressions, or explaining the meaning of a result. Tasks that primarily emphasize answer production or direct computation are excluded.

For each original task, the prompt generates two scaffolding tasks. For each generated task, it also specifies the targetable cause addressed, the supporting evidence excerpt, the related KC, and the intended intermediate product. In this way, the evidence constructed from student work is carried forward into subsequent task design within one implemented task–evidence–task cycle.

4. EVALUATION

This section evaluates the present implementation by reporting (1) the dataset used in the evaluation, (2) the quality of LLM-based KC extraction (RQ1), and (3) expert and student evaluations of the generated scaffolding tasks (RQ2).

Grade 10 students ($N = 29$) in South Korea provided handwritten solutions, and all personally identifiable information was removed. These were reviewed by the researchers, transcribed into LaTeXformat, and segmented into a line-level solution log dataset for KC-based diagnosis, with each line representing one written step in a student's solution. The generated scaffolding tasks were reviewed by two experts (one mathematics teacher and one mathematics education researcher) and tested in a small-scale follow-up activity examining changes in answer accuracy and solution processes. The diagnosis and task generation processes were implemented using GPT-5.2.

4.1 Data Description

Problem-solving data were collected from 15 tasks on quadratic equations, quadratic functions, and quadratic inequalities at the Grade 10 level. These tasks were categorized into three difficulty levels (easy, intermediate, and difficult) based on their cognitive and procedural demands.

Twenty-nine students freely chose which tasks to solve. One solution per student per task was collected and decomposed into line-by-line units, yielding 1,406 solution logs.

Table 1 summarizes answer accuracy and the average number of solution steps by difficulty level. Easy-level tasks showed 85.1% accuracy with 3.08 steps on average, intermediate-level tasks 75.6% with 4.15 steps, and difficult-level tasks 62.7% with 5.99 steps. Overall, lower accuracy tended to be associated with longer solution processes.

At the individual-task level, the two lowest-accuracy tasks showed 17.6% and 33.3% accuracy, respectively; the latter also had the second-highest average number of solution steps.

Table 1: Summary of student performance by difficulty level

Level	Items	Attempts	Accuracy (%)	Steps
Easy	5	87	85.1	3.08
Intermediate	4	90	75.6	4.15
Difficult	6	118	62.7	5.99

4.2 KC Extraction from Solution Logs (RQ1)

To examine whether the LLM could meaningfully extract KCs from students' solution logs, the model generated 10 KC candidates for each of the 15 tasks. Two experts judged the appropriateness of each of the 150 KC candidates using a binary scale (appropriate = 1, inappropriate = 0).

Inter-rater agreement indicated moderate consistency (Cohen's $\kappa = 0.52$; overall agreement = 0.78), suggesting that judgments about individual KC candidates were not fully stable.

Table 2: Task-level validity and stability of LLM-generated KC candidates

Measure	Value
Strict validity rate (both experts = valid)	0.533
Lenient validity rate ($\geq$1 expert = valid)	0.753
Jaccard similarity (median)	0.750

Task-level analysis further showed a strict validity rate of 0.533, a lenient validity rate of 0.753, and a median Jaccard similarity of 0.750 (Table 2). These results suggest substantial task-level overlap between the LLM-generated KC sets and those identified by expert raters, while also indicating limited agreement on individual KC candidates. The generated KCs should therefore be interpreted as provisional rather than definitive diagnostic units.

We also examined the relationship between the average number of solution steps per task and the average number of valid KCs identified by expert raters. A significant positive Spearman rank correlation was observed ($\rho = 0.52$, $p = .048$), indicating that tasks with longer solution logs tended to yield more expert-validated KC candidates.

4.3 Appropriateness of Generated Scaffolding Tasks (RQ2)

To examine the appropriateness of the generated scaffolding tasks for formative assessment, two experts independently evaluated them using a five-point Likert scale (Table 3). For each original task, two scaffolding tasks were generated, resulting in 30 tasks in total.

Inter-rater agreement, assessed with quadratic weighted Cohen's kappa, was substantial (0.76 for Scaffolding Task 1 and 0.73 for Scaffolding Task 2). Both experts also assigned mean ratings above the midpoint of the scale (Expert 1: M = 3.53, SD = 1.50; Expert 2: M = 3.83, SD = 1.46), indicating generally positive evaluations and suggesting that the generated scaffolding tasks were reasonably appropriate for formative use.

Table 3: Evaluation criteria for the appropriateness of scaffolding tasks

Score	Description
1	The task is unrelated to the original task or is mathematically invalid
2	The task is almost identical to the original task and is not appropriate as a scaffolding task (mere repetition)
3	The scaffolding task focuses on a peripheral KC and should be revised to target a more central step
4	The KC level targeted by the scaffolding task is appropriate, but minor revisions to numbers or wording are needed
5	Very appropriate as a scaffolding task for the original task

Table 4: Example of an original task and two LLM-generated scaffolding tasks

Task	Description
Original task	You plan to create a rectangular garden with an area of at least $400\,m^2$. The perimeter of the garden is $100\,m$, and the length of the longer side is $x\,m$. Find the range of possible values of x. (Assume that the length is greater than the width.)
Scaffolding task 1	For a rectangle with perimeter $100\,m$, express the width in terms of x when the length is $x\,m$. Then write the condition "the length is greater than the width" as a single inequality in x.
Scaffolding task 2	For a rectangle with perimeter $100\,m$, when the length is $x\,m$, rewrite the condition that the area is at least $400\,m^2$ as a single quadratic inequality involving only x.

To obtain preliminary qualitative observations, a follow-up re-solving activity was conducted with four students who had answered incorrectly on the two original tasks with the lowest initial answer accuracy. The students were provided with the original task together with scaffolding tasks that experts had judged to be appropriate.

For the lowest-accuracy task, two of the four students answered correctly in the re-solving attempt, whereas two remained incorrect. For the second-lowest-accuracy task, which involved a longer solution process (Table 4), three students answered correctly and one remained incorrect. Qualitative review of the re-solving processes showed that some students stated previously omitted conditions or added intermediate expressions that were absent from the original solutions. These observations indicate that student responses differed across the two tasks in terms of both final correctness and the procedural changes observed during re-solving.

5. DISCUSSION

Regarding RQ1, the results suggest that an LLM can generate plausible KC candidates from students' step-by-step solution logs, with moderate consistency in expert judgments. The agreement and task-level overlap measures indicate that the generated KC candidates generally fell within a range experts considered appropriate, although the exact KC sets did not always coincide. Thus, the generated KCs are better interpreted as provisional diagnostic units than as definitive representations of student knowledge. The positive relationship between the number of solution steps and the number of valid KCs further suggests that the LLM responded systematically to differences in procedural evidence rather than producing arbitrary KC sets.

Regarding RQ2, expert evaluations showed substantial agreement on the appropriateness of the generated scaffolding tasks, suggesting that the LLM-produced tasks were generally suitable for formative use. Rather than directly drilling individual KCs or simplifying the original tasks, these tasks were designed to elicit intermediate products that make learners' thinking visible, such as stating conditions, constructing relational expressions, or articulating the meaning of a solution. This design characteristic aligns with the view that formative assessment tasks should reveal learners' reasoning processes and support the reconstruction of missing or weak procedural steps [2, 14].

The follow-up study with four students provided additional qualitative observations about the potential usefulness of the generated scaffolding tasks. In these cases, some students stated previously omitted conditions or added intermediate expressions after working on the generated tasks. These observations indicate that the tasks may have prompted procedural actions that were not visible in the original solutions, although this interpretation remains tentative given the small-scale design. Differences in responses across the two tasks may reflect differences in their cognitive demands, suggesting that the usefulness of scaffolding may depend partly on task characteristics. Future research could examine how the cognitive demand levels of KCs and interactions among multiple KCs relate to scaffolding design and effectiveness.

Theoretically, this study illustrates how a task–evidence–task cycle can be implemented between the task space and the evidence space within an ECD framework. The present design shows how evidence derived from learners' performances can be organized into diagnostic representations and used to inform subsequent task design in a formative assessment context. In this sense, the study provides a preliminary illustration of how an LLM may support diagnostic interpretation and subsequent task generation within an ECD-based assessment process.

Practically, we envision the proposed pipeline as a teacher-in-the-loop support tool that generates candidate scaffolding tasks from student solution logs. This workflow may help reduce teacher burden by supporting the design of follow-up formative tasks while preserving teacher control over task selection, revision, and classroom use. Future work could examine how this process functions in authentic classroom settings and how the framework may be extended to include the Claim Space within a broader ECD process.

6. CONCLUSIONS AND LIMITATIONS

This study implemented one task–evidence–task cycle by connecting students' solution logs (task space) with KC-based diagnostic evidence (evidence space) to generate formative

scaffolding tasks. Preliminary results suggest that an LLM can generate plausible KC candidates from students' solution logs and that tasks with richer procedural evidence tended to yield more expert-validated KC candidates. Expert review and a small-scale follow-up activity further suggested that the generated scaffolding tasks may help students recognize and produce intermediate products required for problem solving. Together, these findings provide preliminary feasibility evidence that an LLM may support one evidence-informed task–evidence–task cycle for formative assessment grounded in learners' observed problem-solving processes.

Several limitations should be noted. First, the present study examined only a single implemented task–evidence–task cycle rather than repeated cycles across multiple rounds. Second, the study was limited to algebraic topics, specifically quadratic equations, quadratic functions, and quadratic inequalities, and did not examine other areas of mathematics such as geometry or statistics. Third, our evaluation of KC extraction focused on precision, but could not assess recall without predefined reference KC sets for each task. Future work should establish such reference sets for comprehensive evaluation. Fourth, the follow-up study involved only a small number of students and did not include a control group. Therefore, the follow-up findings should be interpreted as preliminary qualitative observations.

ABSTRACT

With the widespread adoption of digital learning environments, learning support utilizing log data collected from Learning Management Systems (LMS) has garnered significant attention. However, many conventional learning analytics rely on aggregated metrics such as total study time or the number of accesses, thereby failing to capture complex temporal dynamics, such as the sequential context of learning behaviors. In this study, we propose an unsupervised anomaly detection method that extracts atypical behaviors that deviate from standard learning patterns using students' behavior stream data. Specifically, we use a Transformer Encoder to generate contextualized embedding vectors from the time-series sequences of learning behaviors, and apply an Isolation Forest to detect anomalous behaviors without incurring labeling costs. Experimental results using actual university learning log data confirmed that the majority of the detected anomalous behaviors were immediate exits (i.e., merely opening and closing materials) lacking the context of page transitions. While these anomalous behaviors were predominantly observed among low-performing students (F and D grades), approximately 30% of the logs classified as anomalous belonged to high-performing students (A grades). Atypical behaviors extracted through unsupervised anomaly detection suggest the inclusion of not only indications of learning deficiencies, such as immediate exits, but also advanced learning strategies adopted by high-performing students, such as the concurrent study of multiple materials and the marking of crucial sections.

1. INTRODUCTION

The widespread adoption of digital learning environments has led to increased interest in learning analytics utilizing log data collected from Learning Management Systems (LMS). Many conventional analyses have relied on aggregated metrics, such as access frequency and total learning time, which fail to capture complex temporal dynamics, including the sequential context of learning behaviors. For example, even with the same number of actions, the learning process of a student who rapidly skips through pages differs fundamentally from that of a student who occasionally returns to review previous content. To address this issue, we propose an unsupervised anomaly detection method that considers the context of learning behaviors. In educational data, clearly defining what constitutes effective or ineffective learning and manually labeling such data entails substantial labor and computational costs. Furthermore, supervised learning carries the risk of overlooking unknown learning strategies that do not fit into predefined categories. Therefore, we adopted an approach that establishes the standard learning behaviors exhibited by the majority of students as a baseline and detects anomalous behaviors deviating from this norm in an unsupervised manner. Specifically, we use a Transformer Encoder [9] to convert temporal sequences into feature vectors that retain contextual information, and then detect anomalous behavior patterns using an Isolation Forest [6]. The main contributions of this study are as follows:

- Context-aware feature extraction: We proposed an embedding method that captures the structure of temporal behavior sequences by combining Inverse Document Frequency (IDF) weighting based on action frequency with a Masked Language Modeling (MLM) task.
- Construction of an unsupervised anomaly detection pipeline: We built a framework that eliminates the costs and biases associated with labeling, directly extracting distinctive behaviors from behavioral stream data.
- Validation of effectiveness using real-world data: Through experiments using actual university learning logs, we demonstrated that the proposed method can accurately extract not only a lack of learning, such as immediate exits, but also advanced learning strategies employed by high-performing students.

proposed a method for predicting academic performance by representing the occurrence counts of actions within digital materials as histogram features [5]. While this method is effective in capturing overall grade trends, it relies on the mere aggregation of actions, leading to the loss of sequential and contextual specificities of learning. Recently, sequence modeling using Transformer architectures has gained significant traction in EDM. For instance, models such as Self-Attentive Knowledge Tracing (SAKT) [8] and SAINT [1] have successfully applied attention mechanisms to model complex dependencies in student interaction sequences. While these models excel in processing sequential data, they are primarily designed for supervised tasks, such as predicting correctness or final grades. Consequently, they require substantial labeled data and risk overlooking novel or atypical learning strategies that fall outside predefined categories. On the other hand, as an attempt at anomaly detection considering sequential context, Jiang et al. proposed an approach that models sequential data using self-supervised learning and detects anomalous learning behaviors based on the prediction error of the next action [4]. However, because this method relies on unidirectional prediction from the past to the future, it is limited by its inability to fully capture bidirectional dependencies of preceding and succeeding actions. To resolve these issues, this study proposes an anomaly detection approach that extracts unknown, atypical learning patterns in an unsupervised manner using an Isolation Forest, while simultaneously preserving the contextual information of the action sequences through the use of a Transformer Encoder.

3. PROPOSED METHOD

The proposed method consists of three components: training an embedding model via an MLM task, generating vector representations of behavior patterns by averaging the vector representations of individual actions, and detecting action sequences containing anomalous behaviors using an Isolation Forest. An overview of the proposed method is shown in Figure 1.

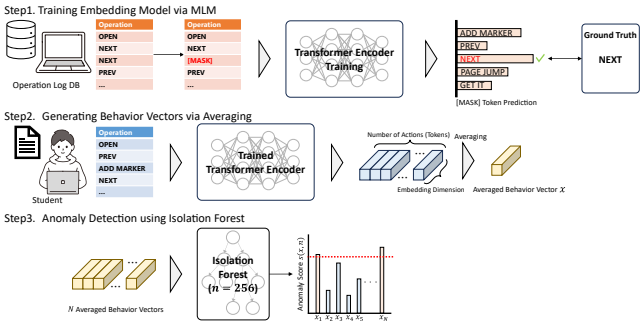

Figure 1: Overview of the proposed method.

3.1 Training the Embedding Model via MLM Task

A Transformer Encoder is utilized to acquire vector representations that capture contextual information from the time-series data of learning behaviors. During training, a Masked Language Modeling (MLM) task was employed to account for the relationships with preceding and succeeding actions. Within the learning behavior logs serving as training data, a significant imbalance exists between actions that are frequently performed by many students and those that occur rarely. Because it is crucial to consider not only the simple frequency of occurrence but also how common an action generally is, this method adopts Inverse Document Frequency (IDF)a metric focusing on the proportion of students who performed the action as a weight for the loss function. Building upon the architecture of BERT-Base [2], the model maps each discrete action into a dense continuous space. The embedding dimension was set to 768, following the standard configuration of BERT-Base, to preserve sufficient representational capacity for modeling complex behavioral patterns. This allows the model to learn structural dependencies, such as in what sequence or context a certain action is likely to occur, factoring in the specificity of the learning behavior rather than relying solely on raw action frequencies.

3.2 Generation of Behavior Pattern Vector Representations via Averaging

The Transformer Encoder, optimized through the MLM task, is used to extract features from the learning behavior sequences targeted for anomaly detection. Each learner's sequence of actions is fed into the model to obtain contextualized vector representations for the individual actions constituting the sequence. Subsequently, the obtained vector representations of each action are averaged over the length of the action sequence. Through this process, a fixed-length vector representing the entire sequence of learning behavior patterns is generated while preserving the context of individual actions. This enables the comparison and evaluation of diverse action sequences of varying lengths within a unified feature space.

3.3 Construction of the Isolation Forest

An Isolation Forest, an unsupervised anomaly detection algorithm based on decision trees, is applied to the generated averaged behavior vectors. During the construction phase, the data is recursively partitioned into two by randomly selecting a feature and a split point randomly determined between its maximum and minimum values. By repeating this process, numerous decision trees are constructed to form the forest.

3.4 Anomaly Detection Based on Path Length

Using the constructed Isolation Forest, the anomaly score for each behavior sequence is calculated based on the average path length required for the data point to become isolated in a leaf node. The anomaly score is defined by Equation (1).

$$s(x, n) = 2^{-\frac{E(h(x))}{c(n)}} \tag{1}$$

Here, x is the data point, $h(x)$ is the path length required for data x to reach a leaf node, $E(h(x))$ is the average path length across all decision trees, and $c(n)$ is the average path length for a dataset of size n. Normal data require many splits to be isolated, whereas anomalous data are isolated with fewer splits, generally resulting in shorter path lengths. This property is leveraged to detect anomalous behaviors.

Table 1: Results of anomaly detection.

Result	Count	Ratio [%]	Avg. Actions	Grade Distribution [%]				
				A	B	C	D	F
Normal	1,389	94.9	152.2	38.7	27.1	19.8	9.8	4.6
Anomalous	74	5.1	30.6	28.4	16.2	23.0	21.6	10.8

4. EVALUATION EXPERIMENTS

In this experiment, an Isolation Forest was applied to the feature vectors generated by the proposed method to calculate the anomaly score of each action sequence. Subsequently, the top 5% of the calculated anomaly scores were extracted as anomalous action sequences.

4.1 Datasets

In this study, we used learning behavior log data from 1,446 students, collected via the learning management system BookRoll [7, 3] during lectures conducted at Kyushu University between the 2019 and 2022 academic years. The data consists of seven courses, labeled A through G, which vary in lecture content and instructors. For the experiment, the log data was restricted to activities occurring within lecture hours, and was divided into training data (data up to the 2021 academic year) and evaluation data (data from the 2022 academic year). The logs contain detailed records of learning operations, such as user IDs, operation types, and operation timestamps. Among all operations, NEXT accounts for approximately 61% and PREV for about 27%, meaning these two page transition operations alone constitute nearly 90% of the total.

4.2 Experimental Results

Table 1 presents the results of the anomaly detection. In the evaluation data, while the average number of actions for normal data was approximately 152.2, the anomalous data averaged only 30.6 actions, confirming a significant tendency for fewer actions in the latter group. Examining the grade distribution, the anomalous data group exhibited a higher proportion of F and D grades. Conversely, students with an A grade also accounted for nearly 30% (28.4%) of the anomalous data. This is likely because the detection captured weeks where students exhibited atypical behavior patterns differing from standard learning behaviors, or weeks where the number of actions significantly decreased due to extremely short study times caused by arriving late or leaving early.

4.3 Ablation Study on IDF Weighting

To verify the effectiveness of IDF weighting, we compared the anomaly detection results with a model that does not use IDF (the baseline). Table 2 shows the anomaly detection results without IDF. Compared to Table 1, while no major differences were observed between the presence and absence of IDF in terms of the total number of detections or the average number of actions, the proposed method incorporating IDF showed a slight tendency to improve the detection rate of students in the lower academic tiers (F and D grades). Furthermore, approximately 75% (55 instances) of the extracted anomalous data were common to both models, and these were primarily data with an extremely low number of actions, such as immediate exits.

Table 2: Anomaly detection results without IDF weighting (baseline).

Result	Count	Ratio [%]	Avg. Actions	Grade Distribution [%]				
				A	B	C	D	F
Normal	1393	95.2	151.9	38.6	27.1	19.7	9.9	4.7
Anomalous	70	4.8	30.7	28.6	17.1	25.7	20.0	8.6

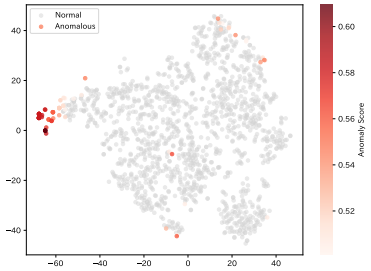

Figure 2: Anomaly score distribution.

5. ANALYSIS AND DISCUSSION

Based on the experimental results from the previous section, we present a detailed analysis of the behavior histories classified as anomalous.

5.1 Qualitative Evaluation by Clustering

To qualitatively evaluate the characteristics of the features generated by the proposed method, we visualized the distribution of the averaged behavior vectors. We employed t-SNE as a visualization method to compress the high dimensional feature space into a two-dimensional plane. For clustering, we utilized the k-means algorithm and set the number of clusters to 14. Figure 2 shows the anomaly score distribution of the generated averaged behavior vectors, and Figure 3 shows the results of clustering and color-coding each action sequence. From Figure 2, it is evident that data with high anomaly scores are densely concentrated at the edge of the feature space, forming an independent region. Correlating this region with the clustering results in Figure 3 revealed that it corresponds to a specific cluster primarily consisting of actions like OPEN (opening materials) and CLOSE (closing materials), accompanied by a low total number of actions. This indicates behaviors where the student immediately exited without reading the content after accessing the system. Furthermore, because these sequences lack the context of page transitions commonly seen among most students, they are isolated in the feature space and are thus considered to have been classified as anomalous. In contrast, the region corresponding to normal data was confirmed to represent typical learning behavior sequences characterized by a high number of actions and frequent page transitions, predominantly NEXT. Here, to confirm the effectiveness of the IDF weighting described in Section 4.3, we compare our findings with the clustering results of the baseline (Figure 4). As shown in Figure 4, in the baseline, sequences primarily consisting of OPEN and CLOSE are mixed within the same cluster, grouped together simply as the opening and closing of materials. In contrast, in the proposed method (Figure 3), these are placed in distinct clusters, indicating that the differences between each operation are captured more clearly.

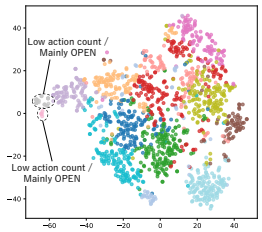

Figure 3: Clustering results of the proposed method.

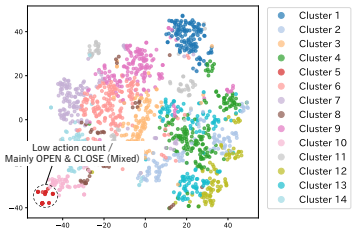

Figure 4: Clustering results of the baseline.

Table 3: Comparison of operations between the top 5 and lowest 5 anomaly sequences.

	OPEN	CLOSE	NEXT	PREV
Top 5 anomalies	3	4	1	0
Lowest 5 anomaly scores	14	10	601	206

5.2 Comparison of Operations between Anomalous and Normal Data

To clarify the specific breakdown of anomalous behaviors, we compared the constituent operations and total action counts of the top 5 anomaly sequences and the sequences with the lowest 5 anomaly scores (Table 3). The top 5 sequences exhibited an extremely low number of operations; while OPEN occurred 3 times and CLOSE 4 times, the primary page transition operations NEXT and PREV occurred only 1 and 0 times, respectively. This indicates instances of closing materials without reading or sessions ending immediately, demonstrating that the sheer lack of learning behavior is successfully detected as anomalous. On the other hand, the sequences with the lowest 5 anomaly scores involved over 800 total operations, with NEXT (601 times) and PREV (206 times) accounting for the vast majority. The ratio of NEXT to PREV is approximately 3:1, suggesting a steady learning pattern of advancing through the material and occasionally returning to review. Stable learning sessions are also evident, with OPEN and CLOSE occurring more than 10 times each. These results demonstrate that the proposed method distinguishes sequences based not merely on quantitative differences, but structurally on the presence or absence of continuous learning behaviors involving NEXT and PREV.

5.3 Analysis of High-Performing Students in the Abnormal Group

As shown in the previous sections, the majority of anomalous behaviors consist of immediate exits. However, among the A-grade data classified as anomalous, there are exceptional cases featuring a high number of operations. To elucidate this specificity, we extracted the operational breakdowns of A-grade students who recorded 100 or more operations (Table 4). Table 4 reveals that these are distinct learning behaviors entirely different from simple exits. A specific student (ID: D-2022_U89) stood out with 23 material openings and closings and 303 page transitions, strongly suggesting comparative learning by frequently navigating back and forth between multiple materials. The other three students demonstrated a high frequency of operations related to markers and memos relative to their page transitions, indicating a meticulous study style of remaining on specific pages to organize important sections. While normal data is predominantly characterized by continuous page transitions, these anomalous instances represent behaviors distinct from standard browsing, such as the concurrent study of multiple materials and the extensive marking or note-taking of critical sections. Here, when compared with the baseline detection results, it is evident that the proposed method captures more of these distinctive behaviors of high-performing students. Specifically, while the baseline detected only two of these students (D-2022_U89 and D-2022_U68), the proposed method successfully detected all four, including those utilizing markers and memos (D-2022_U14 and D-2022_U47). This outcome proves that the proposed method can detect not only a simple lack of learning but also the advanced learning behaviors adopted by high-performing students.

Table 4: Operational breakdown of A-grade students classified as anomalous with 100 or more operations.

Student ID	Open/Close	Page Transition	Marker	Bookmark	Memo	Handwritten Memo	Total	Baseline	Proposed
D-2022_U89	23	303	0	0	0	0	326	✓	✓
D-2022_U68	7	46	84	5	23	1	166	✓	✓
D-2022_U14	2	44	62	0	5	0	113	–	✓
D-2022_U47	2	35	70	0	0	0	107	–	✓

6. CONCLUSION

In this study, we proposed and evaluated an unsupervised framework for anomalous behavior detection using context-aware behavioral features and an Isolation Forest. Experimental results demonstrated that anomalous data frequently lacked context due to immediate exits and contained a high percentage of F and D grades, whereas normal data involved continuous page transitions and contained a high percentage of A grades. Detailed analysis suggested that continuous learning actions involving page transitions, the concurrent study of multiple materials, and the marking or note-taking of important sections are advanced behaviors that contribute to academic improvement. Future research will focus on developing more sophisticated anomaly detection methods by incorporating temporal information, such as page stay time, to capture qualitative differences in browsing behavior.

Vizart: A Multimodal LLM System to Support Visual Learning

Susanna Atanessian

ABSTRACT

Creating high-quality educational visualizations remains time-consuming and difficult to personalize at scale. We introduce *Vizart*, a multi-agent framework for end-to-end text-to-visual generation in Scalable Vector Graphics (SVG) that supports visual learning. By treating visualization as a code-generation task in SVG, *Vizart* utilizes the reasoning and coding capabilities of Multimodal Large Language Models (MLLMs) while addressing their known limitations in spatial reasoning and pedagogical alignment. The framework combines retrieval-augmented in-context guidance, staged scenario and code planning, incremental SVG generation, rubric-based iterative refinement across specialized agents, and user-driven refinement of generated visuals. In an initial study of 100 prompts spanning five subject domains — biology, physics, chemistry, mathematics, and computer science — *Vizart* demonstrates promising early results in generating clear, structured, and pedagogically aligned explanatory visualizations. All code and products are open-source and accessible at `https://github.com/susanna-at/vizart`.

1. INTRODUCTION AND RELATED WORK

Visual learning is an effective pedagogical modality across subject areas and is widely used to support explanations of complex systems and deepen understanding of verbal and written material. Prior work in education and learning sciences has shown that visualizations can be a powerful support for learning, understanding, and long-term recall [1, 11]. Research on intelligent tutoring systems has demonstrated the value of graphic visualizations and representational competency supports for enhancing learning outcomes [7, 10]. However, while students often require visuals to address specific learning needs, designing high-quality educational visualizations can be a significant burden on educators, requiring substantial time and often specialized design skills. These findings motivate the development of systems that target visual learning and can make high-quality educational visualizations more accessible, adaptable, and personalized. The emerging capabilities of Multimodal Large Language Models (MLLMs) create opportunities to generate visualizations at a scale and level of accessibility that were previously difficult to achieve. *Vizart* is inspired by this opportunity. Recent efforts in computing education have explored generative AI for tutoring-style assistance, instructional support, immediate feedback, and coding/debugging support [6]. Systems such as 61A Bot, an LLM-based homework assistant for a large introductory programming course, illustrate this potential at scale [12]. However, these efforts primarily focus on dialogue-based tutoring and code-centered support, leaving generative AI for visual learning comparatively underexplored.

MLLMs have demonstrated strong capabilities in code generation, contextual understanding, dynamic debugging, and iterative optimization [3]. Many visualization formats allow visual generation to be formulated as a code generation task. One particularly useful representation is Scalable Vector Graphics (SVG), an XML-based markup language for creating high-resolution vector graphics. Treating visual generation as code generation enables us to leverage the inherent strengths of MLLMs and is especially promising for scientific and educational applications, which often require high specificity, precision, and clarity. Representing visuals as code, therefore, offers important advantages: it enables finer-grained control over the generation process and allows direct editing and refinement after the image is produced.

Prior work has explored SVG and text-to-SVG generation frameworks. StarVector [9] demonstrates that MLLMs can translate semantic understanding of visuals into SVG primitives. SVGenius, a recent benchmark for SVG understanding, editing, and generation, shows that although current models have promising SVG capabilities, they still face substantial challenges in robust SVG processing, particularly as task complexity increases [2]. Some prior work has studied SVGs as a medium for visualizing hints in mathematics problems [5]; however, frameworks for more involved pedagogical visualization tasks that generalize across subject domains remain underexplored.

Most notably, general-purpose MLLMs are primarily optimized for visual aesthetics rather than instructional clarity. Consequently, existing approaches struggle to handle complex instructional diagrams and often fail to maintain the

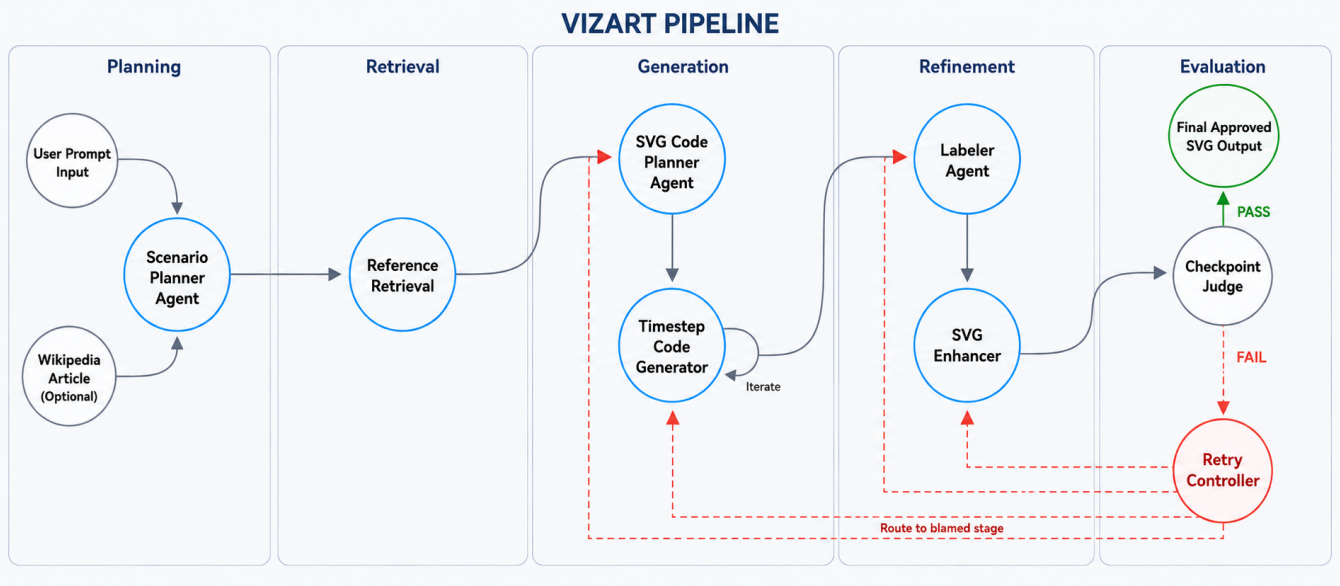

Figure 1: End-to-end overview of the *Vizart* pipeline across its five stages: planning, retrieval, generation, refinement, and evaluation.

precise spatial reasoning, semantic relationships, and geometric constraints required for accurate pedagogical representation [2]. EduVisBench and EduVisAgent further show that, although foundation models can produce step-by-step textual reasoning, they still struggle to generate pedagogically effective visual explanations that are clear, logically structured, and aligned with human cognitive processes [4]. Thus, general-purpose, single-pass generation pipelines fundamentally lack the scaffolding required for education.

To address these limitations, we introduce ***Vizart***, a multi-level human-in-the-loop framework for end-to-end text-to-SVG generation tailored for visual learning. *Vizart* is centered on structured element-level generation and iterative refinement. It aims to leverage the coding abilities of foundation MLLMs while addressing their limitations in spatial reasoning, clarity, and pedagogical alignment.

2. METHODOLOGY AND PIPELINE

Vizart is a multi-agent framework for end-to-end text-to-SVG generation designed to support visual learning. We adopt SVG as the intermediate representation between the language model and the visualization. This choice is motivated by both the broad availability of SVG/XML data on the web and the demonstrated ability of MLLMs to generate and manipulate structured code. As part of *Vizart*, we curate a dataset of more than 5,000 SVG visualizations, equally balanced across five subject areas: *biology, physics, chemistry, mathematics, and computer science*. The dataset is constructed by scraping English-language SVG visualizations from Wikimedia Commons and recording their associated articles as topical context. We applied automatic quality filters such as rendering validation, followed by manual review for subject relevance. We preserve original source URLs and Wikimedia Commons license metadata for attribution. The resulting files contain a median of 86 SVG elements per visualization and are 72 KiB on average. The dataset serves as both an example source and a retrieval base for in-context generation guidance. Given a user request and optional background context, *Vizart* performs a text-based retrieval step over the topic-matched SVG dataset using BM25 [8] and keeps the top-k most relevant examples as references for in-context learning in the downstream generation task of the *Code Planner* stage.

As illustrated in Figure 1, the pipeline begins with a user's natural-language query and optional supporting context, such as a linked article, book section, or other educational resource. In our experiments, we use Wikipedia articles from the dataset metadata as an example of external context. All agents reason over a shared unit of construction called an *element*. An element is defined as a logical structural unit of the figure; it may consist of one or more SVG tags, but it is treated as a single visual unit during planning and generation.

The **Scenario Planner** interprets the request and produces a step-by-step pedagogical visualization plan. It determines how the concept should be visualized, what should be shown, in what order, and at what level of detail for the intended learner.

The **Code Planner** translates this high-level visual plan into an SVG implementation blueprint. It creates a guided plan with actionable coding steps for translating the scenario specification into SVG code. It specifies the approximate layout, visual structure, and the SVG/XML elements needed to realize each part of the figure.

The **Timestep SVG Code Generator** executes the code plan incrementally, stage-by-stage, rather than in a single pass. At each stage, it receives the current SVG state, the instructions for the next step, and the original user intent, and progressively updates the figure. This incremental ap-

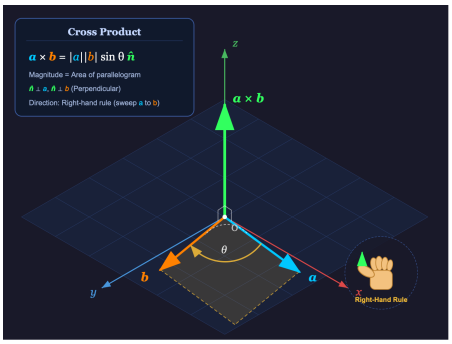

Figure 3: *Vizart* output for mathematics: cross product.

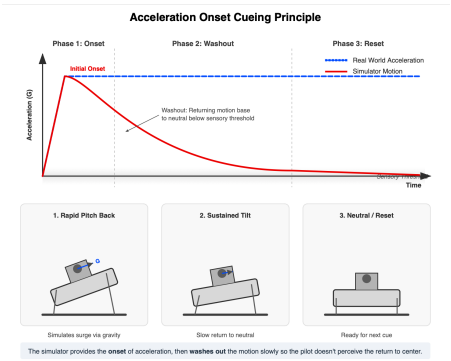

Figure 4: *Vizart* output for physics: onset cueing.

proach mirrors how a human developer would construct a complex diagram — building up the visual element by element, verifying intermediate results, and adjusting as the figure takes shape.

The **Labeler** controls annotations. The *Labeler* determines which labels are necessary for the pedagogical goal, audits existing labels, and issues add, remove, or adjust operations on text tags to improve readability and instructional value.

The **Enhancer** performs final visual refinement. It improves spacing, alignment, and element placement, focusing on presentation quality without altering the intended concept.

The **Judge** evaluates the final visualization using a rubric across four dimensions: visual clarity, layout and visual organization, pedagogical utility, and fidelity to the target concept, averaging to obtain an overall score. Each dimension is scored 1–100. The Judge outputs a binary pass/no-pass decision, concise feedback, and the stage most responsible for the most prominent issue in the case of a no-pass. If figure generation fails, the pipeline can restart from the identified stage with judge feedback injected into downstream agents.

Vizart is designed as a human-in-the-loop system. Because the visualization remains in SVG form throughout generation, intermediate and final outputs are editable. This allows the system not only to regenerate from intermediate stages using judge feedback, but also to support direct refinement and control by instructors or learners. Figure 2 shows the *Vizart* interface. The *Vizart* interactive demo supports all stages of the pipeline with customizable parameters. Users can refine generated visualizations by directly editing the SVG code, manipulating visual elements through the interface, or providing natural-language feedback for regeneration. When feedback is provided, the system can route the revision back through the relevant pipeline stage while preserving the editable SVG representation.

3. RESULTS

In a preliminary study, we evaluated *Vizart* on 100 prompts. Half of the prompts were randomly selected high-school to college-level questions distributed across the five subject categories, while the other half were prompts for which a corresponding ground-truth visualization was available in our Wikipedia-derived SVG dataset. All 100 evaluations were run in fully automated mode (no human intervention) to

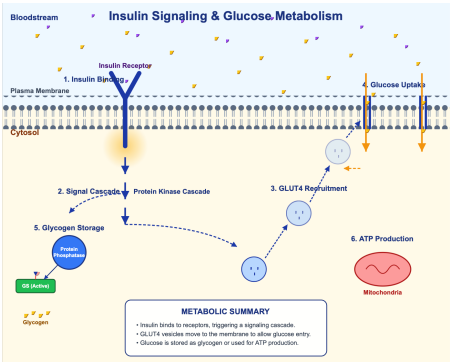

Figure 5: *Vizart* biology output: insulin signaling.

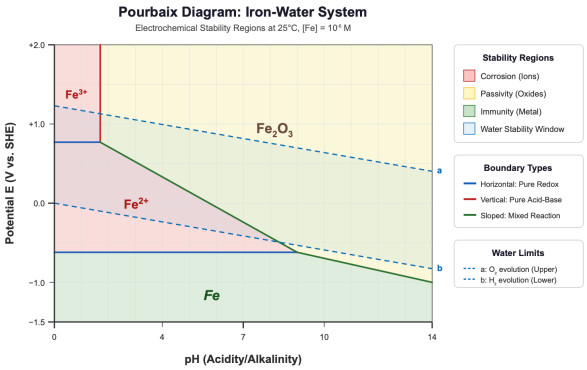

Figure 6: *Vizart* output for chemistry: Pourbaix diagram.

establish a baseline. Judge-based regeneration loops were capped at two iterations. The agent stack used a combination of Gemini-3 Flash Preview and Claude Sonnet 4-6. Gemini was used for planning and judging, while Claude was used for code-generation stages, assigned based on preliminary qualitative comparisons; the architecture is model-agnostic by design. Figures 3–7 show representative *Vizart* outputs across five subject domains.

The average documented judge scores across the four rubric items, alongside human annotator scores on the same rubric, are reported in Table 1. Based on the Judge's binary pass/no-pass decision, the passing rate was 40%. The results in Table 1 show overall alignment between human critique and the LLM as a judge. Across individual criteria, it is notable that the human annotator rated the fidelity to the subject matter and pedagogical value lower than the LLM judge, motivating human-in-the-loop refinement.

4. FUTURE WORK

Vizart creates an exciting foundation for future work in educational visualization. As users interact with the system, provide rubric-based feedback, iterate with the tool, or manually edit generated SVGs, these actions can serve as signals of user preferences and desirable visualization criteria. Such interaction data could support more personalized generation pipelines, including fine-tuning the Judge agent and related components to better match preferences in style, level of detail, and pedagogical presentation. Because different foundation models exhibit different stylistic tendencies, future versions of *Vizart* could also adapt model selection to user preferences and task type. More broadly, as larger amounts of user feedback, interaction traces, and edited outputs are collected, *Vizart* could support stronger human-in-the-loop optimization, including fine-tuning and reinforcement learning from human feedback.

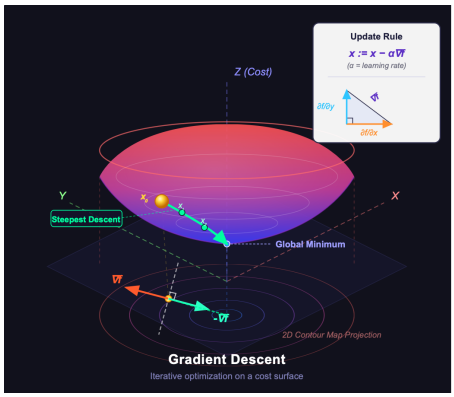

Figure 7: *Vizart* output for computer science: gradient descent.

Table 1: Average LLM judge and human scores across rubric items.

Source	Organization	Clarity	Pedagogy	Fidelity	Overall
LLM Judge	73.3	71.8	81.2	88.1	78.6
Human	68.2	74.9	70.5	75.6	72.3

A second direction is a larger benchmarking and evaluation framework for educational text-to-SVG generation. Such a framework could include broader baseline comparisons, additional metrics for pedagogical quality and visual correctness, and agent-level analysis of where different foundation models succeed or fail. It could also support comparison across domains, levels of contextual input, and degrees of user interaction, helping identify which components of the framework contribute most to final visualization quality.

5. CONCLUSIONS

Generating educational visualizations has long required either design expertise or significant time — often both. *Vizart* offers a different path: by representing visualizations as structured SVG code and orchestrating specialized agents across planning, generation, labeling, refinement, and evaluation, the system enables the production, inspection, and iteration on explanatory figures through natural language alone. Our initial study across five subject domains suggests that this structured, multi-stage approach can meaningfully address the spatial reasoning, label clutter, and pedagogical alignment failures that limit single-pass MLLM generation. The more significant contribution, however, may be architectural. By keeping the visualization in an editable, inspectable format throughout the pipeline, *Vizart* positions instructors and learners as active participants rather than passive recipients of generated content. The human-in-the-loop design is not a fallback for when the model fails — it is central to the system's pedagogical philosophy.

ABSTRACT

Digital learning platforms often give students a chance to solve a similar problem immediately after an incorrect response, a design we refer to here as "*immediate corrective practice*" (ICP). While prior work suggests that immediate feedback and targeted retries can support learning, less is known about how various implementations of ICP affects performance and engagement in real-world settings.

We study ICP using extant large-scale log data from a K–12 mathematics platform where teachers can choose whether to enable a feature that presents supplementary similar problems after errors on eligible items within an assignment. Focusing on students who answered the first eligible problem in an assignment incorrectly, we compare those shown ICP with those assigned the same problem sets but not shown ICP because their teachers did not use the feature. Students who encountered ICP performed better on the next problem, but were also less likely to complete the assignment.

One possible explanation is that additional practice after an error shifts students' perceived endpoint of the assignment, creating a moving-goalpost effect that discourages continued engagement. As large language models make it easier to generate corrective problems and feedback at scale, our findings offer design insights for supporting learning while minimizing disengagement.

1. INTRODUCTION

Digital learning platforms in K–12 mathematics often provide students with immediate feedback on auto-gradable, non-open-response problems. This can take the form of correctness feedback, hints, or a worked explanation. To reinforce understanding, students may also be given opportunities for "*immediate corrective practice*" (ICP), such as solving similar problems they had difficulty with, either immediately after the current problem or after completing the assignment. Examples include "Start Over" feature in Khan Academy [9], "Redo" in ASSISTments [15], and "Quick Retake" in ALEKS [1]. While prior work suggests that immediate feedback and targeted retries can support learning [14, 4], less is known about how different implementations affect student learning and engagement in real-world settings.

This paper studies one particular implementation of ICP in a real-world DLP context. Specifically, we examine the effects of providing students with a similar supplementary problem immediately after an incorrect response within an ongoing assignment. We focus on a naturally occurring setting in a K–12 mathematics platform in which teachers can enable or disable an ICP feature that presents students with a similar problem immediately after they answer a problem incorrectly on the first attempt, provided a similar problem is available. We investigate the following research questions:

- **RQ1**: Does immediate corrective practice improve student performance on the immediate next problem?
- **RQ2**: Does immediate corrective practice affect student completion of the assignment?
- **RQ3**: If the evidence suggests "Yes" to RQ2, is the decrease in persistence purely due to longer assignment length?

2. RELATED WORK

2.1 Benefits of Immediate Feedback and ICP

Immediate corrective practice is closely related to research on feedback and mastery learning. Mastery learning frameworks emphasize iterative cycles of assessment, feedback, and corrective opportunities, where students are given additional chances to practice until proficiency is reached [3,

5]. Similarly, digital learning platforms often provide immediate feedback and targeted retry opportunities after errors, and such approaches have been associated with improved learning, especially for weaker students [2, 11, 14].

The instructional logic is straightforward: when a student makes an error, the platform uses that moment to provide a closely related opportunity to apply what was learned from the immediate feedback. This is especially plausible for procedural mathematics, which benefits from repeated practice.

2.2 Potential Tradeoffs for ICP

Implementations of immediate corrective practice vary across platforms. Students may practice a fixed skill until they reach mastery, practice on similar problems after an assignment, or receive supplementary similar problems woven directly into the assignment they are working on.

Although adding similar problems after an error is consistent with mastery learning, it may not always be beneficial from the learner's perspective. Supplementary ICP within an assignment can provide a timely opportunity to revisit a skill, but it also increases the amount of work. Prior work has shown that assignment size matters for student performance, with evidence that shorter assignments can be associated with better performance than longer ones [12]. This raises the possibility of assignment fatigue, which may reduce students' willingness to complete the assignment.

In addition, research on goal-distance theory [10, 7] suggests that motivation depends on perceived distance to completion. When ICP problems are added after an error, students may perceive the assignment's endpoint as shifting after they have already started the assignment. Thus, while ICP is aligned with mastery learning, its implementation within an assignment may also lower persistence by making the finish line feel farther away than expected.

2.3 Implications for scaling of ICP

Prior to the advent of large language models (LLMs), creating similar problems often required substantial human labor, alongside work on crowdsourcing and learner-sourcing to produce high-quality educational content. Recent research suggests that LLMs can now generate and scale such problems with much less effort [6, 13]. As a result, it is increasingly important to move beyond content quality alone and examine existing implementations to identify better designs for future randomized controlled trials and field testing.

3. DATA AND SETTING

This study used extant de-identified log data collected by a K–12 mathematics digital learning platform, ASSISTments, between Jan 2023 and Dec 2025 [8], with the data collection process approved by IRB. The platform has an ICP feature that, when enabled for an assignment, provides students with a similar problem after an incorrect response on eligible items. We focus on data with these criteria:

- a student attempts the first item in an assignment for which a corresponding similar corrective practice problem is available, even though this is not necessarily the first item in the assignment,
- the student answers this item incorrectly on the first attempt, and
- there is a later non-open-response autogradable item.

These instances represent cases in which immediate corrective practice could potentially be triggered while still allowing measurable downstream outcomes without contamination from earlier ICP exposure. Our two analytic samples consist of student-problem observations meeting these criteria: a *first-instance* dataset with students' first exposure to the feature, and a *full* dataset with all such exposures. We compare outcomes between students exposed to immediate corrective practice and students assigned the same problem sets but not exposed because their teachers did not enable the feature. Assignments with no later auto-gradable item after the ICP-eligible item are excluded.

Finally, to examine whether lower assignment completion is simply due to longer assignments under ICP, we analyzed an *expanded* dataset containing all student assignment attempts between Jan 2023 and December 2025. Using this dataset, we estimated the association between teacher-enabled ICP and assignment completion while controlling for the maximum possible assignment length if ICP were triggered. We use the maximum possible length because ICP is triggered only after incorrect responses, and not all students will answer all ICP-eligible problems incorrectly.

4. MEASURES

Outcome variables. We consider the following outcomes on the immediate next autogradable problem, using the average when the problem has more than one part, as well as completion of the rest of the assignment.

Average next-problem score (RQ 1,2 only): We analyzed these scores in two ways: first, among only students who completed the next problem, and second, with students who skipped the next problem coded as 0. Scoring reflected both accuracy and support use: first-attempt correct responses earned 100%, correct responses after hints or within the second or third attempts earned partial credit (33–66%), and responses requiring more than three attempts or revealed-answer responses earned 0%.

Assignment completion (RQ 1,2,3): Whether the student goes on to complete the assignment, i.e., a binary variable.

Covariates. To control for students' general ability and current performance in the relevant skill, we include the following variables centered on the median:

Prior 5-problem average performance (RQ 1,2,3): student's average performance on the previous five problems before the assignment, used as a proxy for general ability

Initial-item score (RQ 1,2 only): score on the initial item that was answered incorrectly on first attempt, or average score if the problem had more than one part.

Assignment length (RQ3 only): Natural log of the base number of problems if ICP is not enabled, and theoretical maximum number of problems, including ICP, if it is enabled.

4.1 Analytic Approach

We estimated the association between immediate corrective practice and subsequent student outcomes using multilevel regression models fit separately in RQ1 and RQ2 on two datasets: a *first-instance* dataset and a *full* dataset. This allowed us to examine whether results were consistent when focusing on a student's first eligible exposure versus all eligible exposures. Our main predictor for RQ1 and RQ2 was `ICP_seen`, an indicator of whether a student received an ICP problem after an incorrect response.

In RQ3, the main predictor was `use_ICP`, an indicator of whether the teacher enabled the ICP feature for the assignment, and analyzed using the *expanded* dataset. The models include random intercepts for students and teachers, as well as for problems in RQ1 and RQ2 and problem sets in RQ3, to acccount for differences across these units that are not captured by the observed covariates.

4.2 Models for Continuous Outcomes

For next-problem outcomes, we fit linear mixed-effects models using `lmer` from `R`'s `lme4` package with maximum likelihood (`REML = FALSE`).

$$\begin{aligned} Y_{ijkm} = \beta_0 &+ \beta_1 \texttt{ICP_seen}_{ijkm} \\ &+ \beta_2 \texttt{prior5avg}_{ijkm} \\ &+ \beta_3 \texttt{prior5avg}_{ijkm} * \texttt{ICP_seen}_{ijkm} \\ &+ \beta_4 \texttt{initial_score}_{ijkm} \\ &+ u_i + v_j + w_k + \varepsilon_{ijkm} \end{aligned}$$

where Y_{ijkm} denotes the continuous outcome for observation m. Here, u_i, v_j, and w_k denote random intercepts for student, teacher, and next problem respectively, and assumed to be normally distributed with mean 0. Residual error ε_{ijkm} is also assumed to be normally distributed with mean 0.

We applied this specification to the two continuous outcomes: next-problem score average, and its corresponding variant in which students who did not complete the next problem were scored as zero. This allowed us to test whether the observed associations were robust to a more conservative coding of non-completion.

4.3 Models for Binary Assignment Completion

For the binary outcome indicating whether the student completed the remainder of the assignment in RQ1 and RQ2, we fit a generalized linear mixed-effects model with a logit link using `glmer` from `lme4` in `R`. As in the linear models, we included random intercepts for student, teacher, and next problem, with the same distributional assumptions.

$$\begin{aligned} \text{logit}\left(Pr(Y_{ijkm} = 1)\right) = \beta_0 &+ \beta_1 \texttt{ICP_seen}_{ijkm} \\ &+ \beta_2 \texttt{prior5avg}_{ijkm} \\ &+ \beta_3 \texttt{prior5avg}_{ijkm} * \texttt{ICP_seen}_{ijkm} \\ &+ \beta_4 \texttt{initial_score}_{ijkm} \\ &+ u_i + v_j + w_k \end{aligned}$$

where $Y_{ijkm} = 1$ indicates assignment completion. For interpretation, fixed effects from the logistic models were exponentiated and reported as odds ratios. In RQ3, the model is similar, except that we replace `ICP_seen` and `initial_score` with `use_ICP` and `assignment_length` respectively. Due to the size of the *expanded* dataset ($>$ 4 million records), we used `glmmTMB` in `R` which is more efficient for large datasets.

4.4 Bootstrap Inference

Given the complexity of the mixed-effects structure, we used parametric bootstrap resampling with `bootMer` to obtain empirical standard errors for the fixed effects in the models for RQ1 and RQ2. For each fitted model, we generated 500 bootstrap replications by simulating new response values from the fitted model and refitting the model to each simulated dataset, using `type = "parametric"` and `use.u = FALSE`. Bootstrap standard errors were then calculated as the standard deviation of the bootstrapped fixed-effect estimates across replications. However, we did not use bootstrapping for RQ3 because of the dataset size and computational cost of repeatedly refitting the model. Given the much larger sample size in RQ3, we do not expect the substantive conclusions to be sensitive to this choice.

5. RESULTS

Our results suggest a mixed pattern. On one hand, immediate corrective practice appears to provide short-term benefits for students who engage with it. For RQ1, students exposed to ICP show better subsequent performance, consistent with the idea that immediate targeted reinforcement can support learning after an error. This pattern holds even after accounting for students who skipped the next problem.

On the other hand, these benefits come with important engagement trade-offs. For RQ2, exposure to ICP is associated with lower assignment completion. In other words, while ICP may support learning after an error, the additional problems may also discourage students from finishing the assignment.

One way to interpret these results is to distinguish between the *instructional value* of the feature and its *psychological experience*. The same intervention that helps one student consolidate learning may be experienced by another as an unexpected increase in workload. In RQ3, we find that even after controlling for assignment length, ICP remains associated with lower odds of assignment completion. This suggests that lower completion is not due to assignment length alone, and that a perceived shift in the assignment endpoint, consistent with goal-distance theory, may also play a role. *We elaborate on the results in greater detail below.*

Across both the first-instance and full datasets, results were highly consistent. Students who saw the similar next problem (ICP) performed better on the immediate next problem, and this pattern held even when non-responses were recoded as 0 (Table 1). The ICP $\times$ Prior5avg interaction was negative across specifications, suggesting that the performance benefit of ICP was smaller for students with higher prior performance.

At the same time, students who saw ICP had lower odds of completing the assignment in both the first-instance and full

datasets (Table 2). This negative association was somewhat weaker for students with higher prior performance.

In the analysis using the expanded dataset, ICP remained associated with lower completion even after controlling for median assignment length (Table 3) and student performance. The interaction results also point in the similar directions across specifications: the negative association between ICP and assignment completion appears weaker for students with stronger prior performance and stronger for lower-performing students. However, this moderation was estimated more precisely when prior performance was modeled continuously than when it was coded as a lowest-quartile indicator. Given that lower completion is not explained by assignment length alone, it lends credibility that moving the goalpost has led to decreased persistence.

6. DISCUSSION, LIMITATIONS, AND DESIGN IMPLICATIONS

This study is limited by its observational design, so the results should be interpreted as associations rather than causal effects. Because the sample was restricted to students who reached the first eligible problem, we cannot rule out selection or survival bias. Our outcomes also focus on short-term performance and assignment completion, rather than longer-term learning, and the findings are specific to the platform studied.

Within these limits, the results suggest a consistent tradeoff: immediate corrective practice within an assignment is associated with slightly better next-problem performance, but also with lower assignment completion. This suggests that the value of ICP depends not only on the quality of the added problems, but also on how they are implemented. For platform developers, the key question is not simply whether to provide similar problems after errors, but how to design their use in ways that support learning without reducing persistence. This also points to promising directions for future randomized experiments, such as testing alternative implementations that vary how workload changes during an assignment, including reverse moving-goalpost designs that remove problems when students answer correctly. As large language models make it easier to generate similar problems at scale, the main challenge may shift from producing such content to designing better ways to use it.

ABSTRACT

Crowdsourcing platforms like Kaggle provide community-driven mechanisms for team formation and informal learning, yet little is known about how these mechanisms operate across expertise levels. We analyze 1,577 comments from 671 participants across 18 Kaggle "Looking for a Team" megathreads (2023) and identify a systematic attention imbalance by expertise level. Low-tier users (Novice and Contributor) constitute 89.3% of participants, yet higher-tier users attract disproportionate attention in the reply network ($H = 16.46$, $p = .003$). Dyadic regression further confirms that receiver expertise predicts tie formation (OR = 1.28), consistent with preferential attachment. Using linked final team records for 16 competitions, however, we do not observe a statistically significant expertise gap in ending on a multi-member team (41.0% for low-tier vs. 34.7% for high-tier user-competition observations, $\chi^2 = 1.26$, $p = .261$). These results show that megathreads reproduce expertise-based differences in visibility more clearly than in observed final team membership. We identify preferential attachment as a key mechanism underlying this visibility imbalance and translate our findings into design recommendations for more equitable team formation systems.

Keywords

Team Formation, Expert-Novice Differences, Crowdsourcing, Preferential Attachment, Informal Learning

1. INTRODUCTION

Crowdsourcing platforms such as Kaggle have evolved beyond task completion into spaces for professional development and informal learning [2, 12]. As crowdsourcing tasks grow in complexity, collaboration has become essential, encouraging knowledge workers to form teams to tackle data science challenges [6]. The first step of collaboration is team formation, a process that unfolds differently in virtual communities than in traditional organizations because individuals have the autonomy to choose their own collaborators [5].

https://doi.org/10.5281/zenodo.21040055

To facilitate this process, platforms provide spaces for team-seeking behavior. Kaggle's "Looking for a Team" (L4T) megathreads, introduced in 2022, are competition-specific forums where participants post team-seeking messages and reply to potential collaborators [18]. While prior work has examined the general dynamics of megathread conversations and self-representation patterns [18], a critical question remains: who actually benefits from these spaces?

This question has equity implications. If these spaces disproportionately serve users who already have established networks and credentials, they may widen the gap between experts and newcomers rather than close it [7]. We address three research questions:

- **RQ1.** How does expertise level relate to participation patterns and network position?
- **RQ2.** What network mechanisms (preferential attachment and homophily) drive tie formation?
- **RQ3.** Do expert and novice users benefit equally from megathread participation?

Drawing on preferential attachment [1] and homophily [11], we hypothesize that higher-tier users attract a disproportionate share of replies in team-seeking forums and that this visibility advantage may carry over into observed team membership outcomes.

2. RELATED WORK

Group Formation in Online Communities. Research on group formation distinguishes automatic from agency-driven approaches across different contexts [5]. In MOOCs, automatic grouping by activity or demographics can improve satisfaction [14, 19], but such automation potentially removes individual agency. In open communities like Kaggle, human agency dominates. Participants actively seek information about potential collaborators before forming teams [10]. Language proficiency and past collaborations predict team-up decisions positively on Kaggle, while geographical distance and skill disparity show negative effects [3]. However, most studies assume pre-formed teams rather than examining how teams naturally emerge in these communities [6].

Expert-Novice Differences in Crowdsourcing Communities. Crowdsourcing platforms such as Kaggle make expertise visible through status hierarchies: the performance tier system

publicly labels users from Novice, Contributor, Expert, Master, to Grandmaster, and these labels travel with users into team-seeking interactions. Prior work has shown that newcomers in open-source communities face barriers to gaining trust and attracting collaboration [10], and that sharing online profiles and expertise signals predicts collaboration success [13]. What remains underexplored is whether team formation spaces specifically designed to help all users actually achieve equitable outcomes across expertise levels.

Preferential Attachment, Homophily, and Marginality. Preferential attachment, the tendency for well-connected nodes to attract yet more connections [1], and homophily, the tendency for similar individuals to associate [11], are two fundamental mechanisms in social network formation. Wang [17] has argued that marginality, defined as being located at the periphery of a network, might form a team easier than more experienced users in crowdsourcing contexts. Twyman et al. [15] found that network positioning shapes Kaggle competition performance, while Li et al. [9] showed social influence effects in this community. We extend this work by examining how these mechanisms manifest in team-seeking online forums and whether they produce inequitable outcomes for novices.

3. METHODS

3.1 Data Collection

We collected data from Kaggle's official L4T megathreads for all competitions held in 2023 using the Kaggle API. Of 31 competitions identified, 18 featured L4T megathreads created by Kaggle staff. Our dataset comprises two components: (1) megathread comments, totaling 1,577 from 676 unique users across the 18 competitions, and (2) user profiles for 671 users matched to Kaggle's performance tier system (99.3% match rate, five participants do not have a profile).

Kaggle's performance tier system assigns users a tier from 0 (Novice, no activity) to 4 (Grandmaster), with tier 5 reserved for Kaggle Staff. Tiers are awarded based on cumulative competition medals: Novice (no medals), Contributor (profile complete), Expert ($\geq$2 bronze medals), Master ($\geq$1 gold + 3 silver), and Grandmaster ($\geq$5 gold including a solo gold). We operationalize expertise using this tier and create a binary split: Low-Tier (Novice and Contributor, tiers 0–1, indicating no or minimal verified competition achievement) and High-Tier (Expert through Grandmaster, tiers 2–4, indicating at least two verified competition medals).

3.2 Data Analysis

Our analysis proceeds in five stages. First, we constructed a directed reply network from the megathread data using NetworkX [4]. Each node represents a user, and a directed edge from A to B indicates that user A replied to a comment posted by user B. Edge weights represent the number of replies between a pair. The resulting network contains 665 nodes and 1,300 directed edges (density = 0.003). Figure 1 visualizes the reply network, with node color indicating Kaggle performance tier and node size reflecting weighted in-degree (replies received).

Then, we characterized the expertise composition of megathread participants and their comment activity patterns through a tier distribution analysis. Third, we computed in-degree (replies received), out-degree (replies sent), and betweenness centrality for each node, then compare distributions across tiers using Kruskal-Wallis tests. Then, we tested for preferential attachment by comparing the proportion of replies received by each tier against their population share with a chi-squared goodness-of-fit test, and for homophily by computing the E-I index [8], defined as the ratio of cross-tier to within-tier edges, with significance assessed via a permutation test (1,000 permutations). Finally, we fit a dyadic logistic regression that models tie formation as a function of sender tier, receiver tier, tier difference, same-tier indicator, and account tenure, sampling negative dyads at a 3:1 ratio and evaluating with five-fold cross-validation.

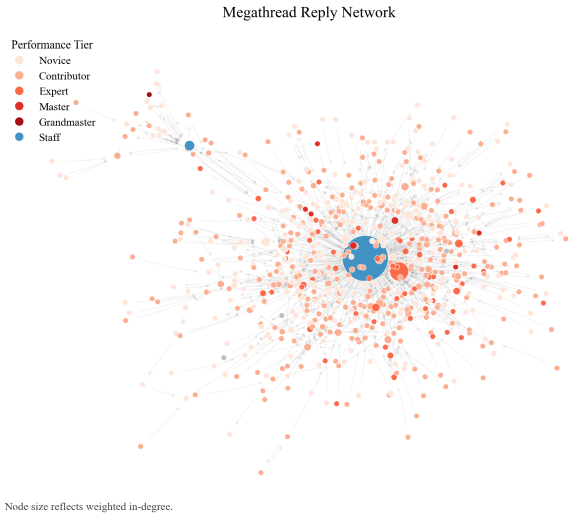

Figure 1: Reply network constructed from Kaggle L4T megathreads. Node color denotes performance tier, and node size reflects weighted in-degree.

3.3 Team-up Success Operationalization

We use a linked competition-team file that connects megathread participants to final team records for 16 competitions. Success is defined as ending on a multi-member team in a given competition (i.e., `NumbersPlayer` > 1). This linked subset contains 382 user-competition observations from 219 unique users, of which 377 observations have matched tier labels. This measure captures observed final team membership directly, in contrast to indirect signals such as medal counts or reciprocal replies.

4. RESULTS

4.1 RQ1: Expertise and Participation

The megathread participant pool is heavily skewed toward lower tiers. As shown in Figure 2, Novice users (tier 0) comprise 42.2% of participants and Contributors (tier 1) comprise 47.1%, yielding a combined low-tier share of 89.3%. Expert users (tier 2) account for only 9.2%, with Master (1.0%) and Grandmaster (0.1%) users nearly absent.

Despite their minority presence, higher-tier users occupy more central network positions. Expert users receive significantly more replies (mean in-degree = 3.32) compared

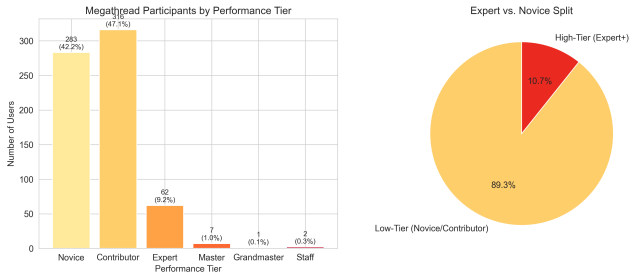

Figure 2: Megathread participants by performance tier (left) and binary expertise split (right). Low-tier users dominate at 89.3%.

Table 1: Population share vs. reply-target share by tier, demonstrating preferential attachment toward Expert users.

Tier	Pop. %	Reply %	Ratio
Novice	42.2	26.2	0.62
Contributor	47.1	29.9	0.63
Expert	9.2	13.9	1.51
Master	1.0	1.1	1.10

to Novice (1.39) and Contributor (1.43) users, with a statistically significant difference across tiers (Kruskal-Wallis $H = 16.46$, $p = .003$). Betweenness centrality also differs significantly ($H = 16.09$, $p = .003$), with Expert users serving as more central bridges in the network. However, outdegree does not differ significantly ($H = 3.82$, $p = .431$), indicating that all tiers send a similar number of replies but receive attention unevenly.

4.2 RQ2: Attachment and Homophily

Preferential attachment. Table 1 compares population share with reply-target share. Excluding Staff (who post the initial megathread announcements), Expert users receive 1.51× their population share in replies, while both Novice (0.62×) and Contributor (0.63×) users receive less than their expected share. A chi-squared test confirms this disproportionality is significant ($p < .001$), supporting preferential attachment toward higher-tier users.

Homophily. The E-I index of 0.125 shows slightly more interaction across tiers than within them, consistent with novices reaching out to experienced users. The permutation test yields $p = .062$, which does not reach conventional significance ($\alpha = .05$), which should be treated as suggestive rather than conclusive. The trend points toward upward-directed attention, but a larger sample is needed before claiming a confirmed homophily effect. Figure 3 shows the reply mixing matrix; low-tier users direct a substantial share of replies toward Staff-initiated threads and cross-tier targets.

Dyadic regression. The logistic regression model achieves a five-fold cross-validated AUC of 0.558. The receiver's tier has a positive coefficient (OR = 1.28), confirming that higher-tier users attract more connections. Tier difference has a negative coefficient (OR = 0.83), indicating that larger expertise gaps slightly reduce tie formation probability. The

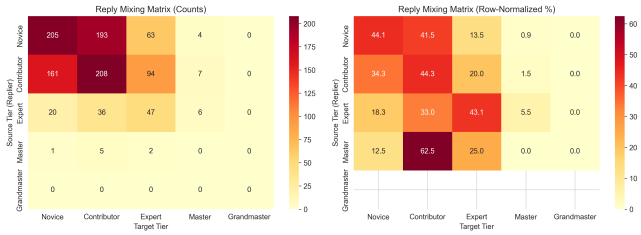

Figure 3: Reply mixing matrix showing interaction patterns between tiers. Left: raw counts. Right: row-normalized percentages.

overall model performance is modest, which is expected for sparse social networks, but the direction and significance of the coefficients support both preferential attachment and weak homophily effects.

4.3 RQ3: Differential Success Rates

Using the linked team-membership data, we do not find a statistically significant expertise gap in final teaming outcomes. As shown in Figure 4, low-tier user-competition observations end on multi-member teams in 41.0% of cases, compared with 34.7% for high-tier observations; this difference is not statistically significant ($\chi^2 = 1.26$, $p = .261$).

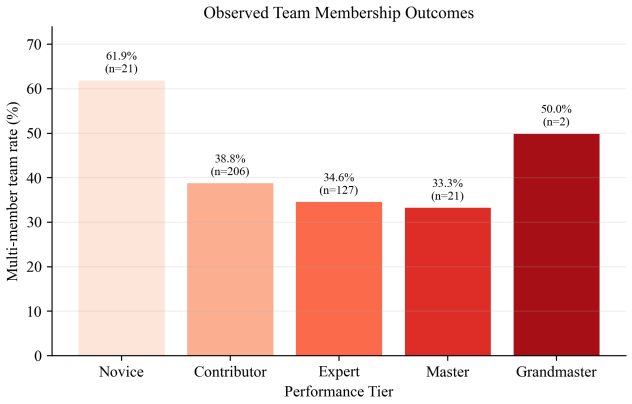

Figure 4: Observed multi-member team rates by performance tier in the linked 16-competition subset. Aggregated to binary groups, low-tier observations reach 41.0% and high-tier observations 34.7%, with no significant difference ($\chi^2 = 1.26$, $p = .261$).

5. DISCUSSION

5.1 Attention Inequality and Team Outcomes

Our findings reveal a mixed pattern. Megathreads are populated mainly by low-tier users, but higher-tier users receive more attention once interaction begins. While higher-tier users receive more attention, they do not necessarily convert that attention into more frequent teaming outcomes, as the multi-member team rates do not differ significantly by tier. Preferential attachment seems only to reproduce inequality in visibility more clearly than in observed final teaming outcomes. Therefore, the megathread mechanism appears to amplify visibility disparities without necessarily

translating them into a significant teaming gap, suggesting that the relationship between visibility and teaming is complex and mediated by other factors [10].

5.2 Why Visibility Does Not Map Onto Teaming

Several mechanisms can explain this misalignment. First, low-tier users overwhelmingly outnumber high-tier users (89.3% vs. 10.7%), so even when high-tier users attract proportionally more replies, the absolute volume of low-tier participants leaves opportunity for novices to find one another and form teams among themselves. Second, attention is not the same as acceptance. High-tier users who received many replies may decline most invitations, screen for quality, or already have established collaborators outside the megathread, so the replies they receive do not necessarily convert into joint team registrations [15]. Third, megathreads are only one of several channels through which Kaggle teams form. Teammates can be recruited via private messages, off-platform networks, or prior competitions, and these channels likely distribute more evenly across tiers than the public reply network does. These dynamics suggest that the visibility imbalance is real and consequential for whose contributions get seen, but it is buffered by the over-representation of novices and by team formation pathways that operate outside the channel.

5.3 Implications

While Wang [17] has argued that marginality is an important indicator of whether a user can form a group in crowdsourcing platform, our finding reveal a challege for novice participants in the crwodsourcing space. Reframing the finding through an equity lens, the absence of a teaming gap is not evidence that megathreads are equitable. Visibility shapes whose questions are answered, whose skills are recognized, and whose presence is registered by the rest of the community, all of which carry weight beyond the binary outcome of ending on a multi-member team. A novice who posts and receives no replies may eventually team with another novice, but the experience of being overlooked is itself an equity-relevant outcome that the multi-member rate alone cannot capture. This motivates design responses targeted at the visibility rather than only the final teaming layer.

Our results suggest several design implications for more equitable team formation. Platforms could provide templates that prompt users to describe their skills, learning goals, and availability, making it easier for novices to present relevant information in comparable ways [13], and temporarily anonymize tier information in team-seeking forums to reduce preferential attachment effects so that evaluation rests on stated skills rather than status labels. Because experts rarely use megathreads, platforms could also design mentorship pathways that incentivize cross-tier collaboration through recognition systems or reduced entry barriers, and offer practice collaborations before competitive events [16] so newcomers can build trust incrementally. These implications extend beyond Kaggle to other online learning communities, such as open-source development, online courses, and professional networking platforms, where similar expert-novice dynamics may exist.

5.4 Limitations

Two limitations bound the scope of our claims. First, Kaggle's performance tier conflates platform experience with domain expertise and is partly circular: tiers are awarded for cumulative competition medals, so higher-tier users are by definition those who have already performed well, and seasoned data scientists new to Kaggle will be misclassified as novices. We treat this as a substantive feature rather than a flaw, since tier labels are the community's shared expertise signal and our study examines how those socially recognized markers shape interaction, but readers should interpret tier as visible status rather than as ground-truth skill. Second, ending on a multi-member team is a coarse outcome that does not establish that the team was actually formed through the megathread, and it does not capture collaboration quality. Future work should link megathread exchanges to teammate identities directly and incorporate more behavioral signals such as notebook sharing and code co-authorship.

6. CONCLUSION

We examined expert-novice differences in Kaggle's "Looking for a Team" megathreads and found that these platform-provided team formation spaces disproportionately attract novice users while directing disproportionate attention toward higher-tier participants. Higher-tier users receive more network attention, but the linked final team records do not show a statistically significant expertise gap in observed multi-member team membership. These findings contribute to ongoing work on equity in online learning communities, showing that platform mechanisms designed for universal benefit can reproduce hierarchies in visibility even when downstream team outcomes are more mixed. We offer concrete design recommendations for creating more equitable team formation systems in competitive learning communities.

ABSTRACT

Educational research often seeks causal evidence about instructional and content design choices, yet randomized experiments can be difficult to run at scale. Although separate content-level experimental studies are technically possible, they are often impractical without substantial infrastructure and coordination. Quasi-experimental studies, whether through design or through post-hoc analysis of non-experimental data, offer opportunities to infer causality from student interactions with learning content. In the context of digital learning platforms, however, the rich process data collected through student interactions has remained underutilized and represents a strong opportunity to better account for confounding that may otherwise go unaccounted for by covariates available in student course, enrollment, and survey data. To address this gap, in this study, we conduct a causal analysis to estimate the effectiveness of an on-demand explanation using a propensity score weighting analysis with data from the ASSISTments digital learning platform. We draw from prior work in educational data mining and AI in education to leverage Deep Knowledge Tracing as a method to estimate propensity scores. We find that requesting an explanation is associated with lower next-problem performance, but we further identify heterogeneous causal effects, suggesting improved short-term learning for higher-effort students who request explanations compared with those who request only the answer. Overall, this study demonstrates how learner-model representations and process measures can strengthen quasi-experimental analyses of platform logs, while emphasizing that the effectiveness of on-demand explanations depends on students' engagement and help-seeking strategies.

1. INTRODUCTION

Educational research increasingly seeks causal evidence to inform instructional and content design decisions. Randomized experiments provide a strong foundation for such evidence and have been successfully deployed in digital learning platforms (DLPs), including studies that systematically vary instructional supports such as hints, feedback, and explanations [14, 15, 17]. However, running experiments comprehensively across the wide range of problems, supports, and learning contexts in large-scale platforms requires substantial infrastructure and coordination, and is often impractical for systems that are already widely deployed. As a result, researchers frequently rely on observational interaction data, raising the challenge of how to draw credible causal inferences from non-experimental platform logs [3, 7].

Causal inference in observational DLP data is particularly challenging because students' interactions with instructional supports are highly non-random. Students who request help often differ systematically from those who do not, not only in prior knowledge but also in engagement, persistence, and other learner characteristics that jointly influence both help-seeking behavior and learning outcomes [11]. These selection effects can substantially bias naïve estimates of instructional effectiveness if not adequately addressed. Recent work in educational data mining (EDM) has therefore emphasized the need for clearly defining causal estimands, evaluating common support, diagnosing covariate balance, and assessing robustness to unobserved confounding [4, 8, 10, 23].

Despite this progress, a persistent limitation of many observational studies is that adjustment for confounding often relies on relatively coarse or static proxies for prior knowledge, such as aggregate accuracy. This is problematic because prior outcomes are often among the most important confounders of treatment [20]. This mismatch is particularly striking given that digital learning platforms record rich, high-dimensional, and temporally structured process data that summarize students' learning histories in far greater detail than is typically used in causal analyses [19].

To address this gap, in this study, we conduct a quasi-experimental causal analysis that leverages learner-model representations to strengthen control for confounding in observational platform data. Using data from ASSISTments, we estimate the short-term causal effect of requesting an

on-demand explanation for a single target problem using propensity score weighting [9]. We first train a Deep Knowledge Tracing (DKT) model on students' historical interactions to produce fine-grained, skill-level mastery estimates that summarize each learner's prior learning history [16]. These mastery estimates are then incorporated as covariates in propensity score estimation [13], following contemporary guidance for machine learning–based causal inference in educational data mining [8, 10]. We compare explanation use against two counterfactual baselines—no on-demand help-seeking and answer-only requests—and examine heterogeneity by engagement, motivated by the hypothesis that explanations may support sense-making use but not rapid task completion. Specifically, we address the following research questions:

RQ 1. What is the effect of requesting on-demand explanations in comparison to students who do not seek help on learning, as measured by correctness on the next problem?

RQ 2. What is the effect of requesting on-demand explanations in comparison to students who ask for the answer on learning, as measured by correctness on the next problem?

RQ 3. Are the effects of explanation use heterogeneous across students with different levels of engagement?

2. METHODS

2.1 Dataset

The data[1] were drawn from ASSISTments, a digital learning platform widely used in U.S. middle school mathematics instruction. We focus on students who attempted a target problem and a subsequent problem assessing the same skill (7.RP.A; proportional reasoning). The target problem was completed by 12,697 students, of whom 7,179 answered incorrectly and were included in the analytic sample.

Students could optionally request on-demand supports while solving the target problem. As shown in Figure 1, the explanation provides step-by-step guidance, whereas Figure 2 shows the answer-only view, which reveals the final solution without intermediate steps. The outcome is a binary indicator of correctness on the subsequent problem (968 correct; 6,211 incorrect). Student interaction logs included problem attempts, correctness, skill identifiers, and help-seeking actions. These data were used to construct prior knowledge measures and behavioral indicators such as time-on-task.

2.2 Data Processing

Problem-level logs were transformed into student–skill sequences. Each problem attempt was mapped to a skill identifier, and each unique skill, including multi-skill combinations, was treated as a distinct category (as suggested in [22]), resulting in $K = 189$ skills. (All 189 skill labels are available on the Open Science Framework (OSF))[2]. The final processed dataset consisted of 1,700,234 problem-attempt rows from 7,179 unique students, with each row aligned to a single student, a single encoded skill, and a unique row identifier to support downstream model training and post hoc analyses.

[1]This study involves post hoc analysis of platform log data conducted with approval from an Institutional Review Board (IRB). Data access may be granted through a data-sharing agreement with ASSISTments.

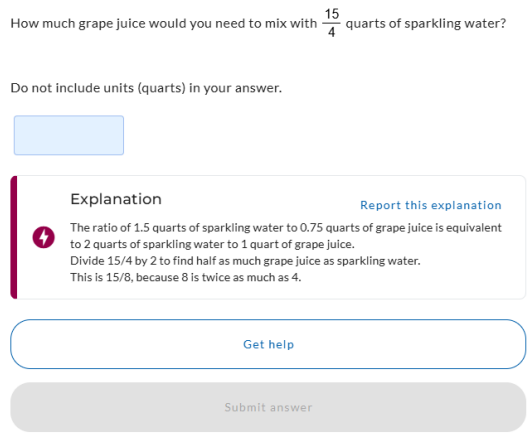

Figure 1: An explanation as it appears in ASSISTments.

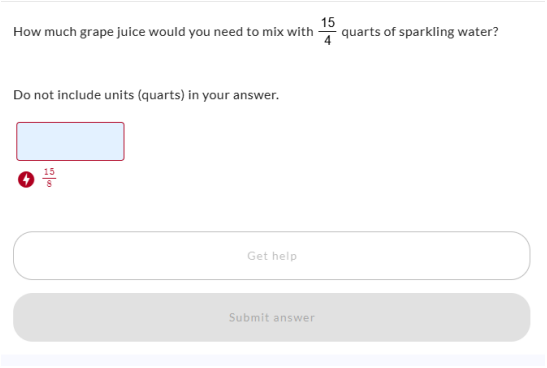

Figure 2: The answer as it appears in ASSISTments.

2.3 Analytic Approach

To estimate the causal effect of explanation use, we combined learner modeling with propensity score weighting (PSW). First, we trained a DKT model on students' interaction sequences to obtain skill-level mastery estimates. Students with fewer than two interactions ($n = 30$) were excluded, yielding 7,149 students. The model was trained using an LSTM architecture with 10-fold cross-validation to generate out-of-fold predictions (AUC = 0.742), which were used as high-dimensional covariates representing prior knowledge.

Next, we constructed mutually exclusive help-seeking groups based on students' behavior on the target problem. Students were categorized into three groups: (1) *Explanation*, students who requested an explanation only; (2) *Answer-only*, students who requested an answer only; and (3) *No-help*, students who did not request any help. The final analytic sample included 821 students in the Explanation group, 3,659 in the Answer-only group, and 1,535 in the No-help group.

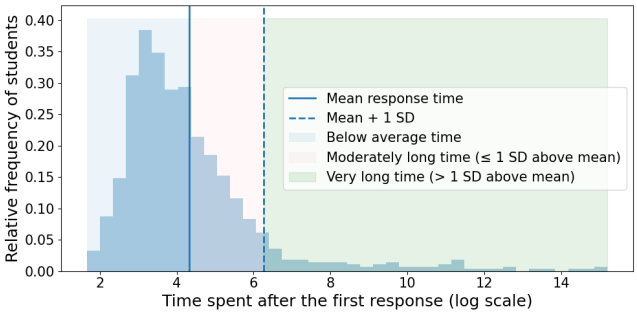

Figure 3: Distribution of time spent after the first response (log scale) for students in the Explanation group ($n = 816$)

To examine heterogeneity, we defined an effort-based subset within the Explanation group using adjusted time-on-task derived from log data (Figure 3). Time was computed as problem duration minus time to first response and log-transformed due to skew. The *Moderate-Effort* subset included students whose adjusted time fell between the mean and mean plus 0.5 standard deviations ($n = 153$), while the *High-Effort* subset included students whose adjusted time fell between the mean and mean plus 1 standard deviation ($n = 228$).

For causal estimation, we applied PSW to adjust for observed differences between groups [13, 18]. Propensity scores were estimated using multiple models, including logistic regression (LR), gradient boosting machines (GBM), random forests (RF), Bayesian additive regression trees (BART), and neural networks (NN), following recent recommendations for machine learning–based causal inference [10]. Separate propensity score models were estimated for each treatment–control contrast (explanation vs. no-help, explanation vs. answer-only, and effort-based subsets).

For each estimator, the common-support assumption was evaluated by examining the overlap in propensity score distributions between treated and control groups. Models exhibiting limited overlap or extreme propensity scores were excluded. Covariate balance was assessed using absolute standardized mean differences (SMDs), with acceptable balance defined as $|\text{SMD}| \leq 0.25$ [21]. Weights targeting the average treatment effect on the treated (ATT) were constructed such that treated units received weight 1 and control units received $PS/(1-PS)$. Residual imbalance ($0.05 \leq |\text{SMD}| \leq 0.25$) was addressed by including covariates in outcome models.

Treatment effects were estimated using a parametric standardization approach with weighted logistic regression models predicting next-problem correctness [5]. Cluster-robust standard errors were computed to account for classroom-level dependence [12], and statistical uncertainty was quantified using cluster bootstrap resampling (100 replications) to obtain 95% confidence intervals. Sensitivity analyses were conducted using Frank's robustness framework to assess the impact of potential unobserved confounding [6].

3. RESULTS

3.1 RQ1: Effects of On-Demand Explanations Compared to No Help-Seeking

We examined whether requesting explanations affected subsequent performance compared to not seeking help ($n_{control} = 1535$, $n_{treat} = 821$) using PSW based on 189 DKT-derived covariates. Common-support diagnostics indicated adequate overlap for LR, GBM, and BART, while RF and NN exhibited limited or unstable support and were excluded from further analysis. All common-support diagnostics are available on OSF. After weighting, covariate balance improved substantially for LR, GBM, and BART (max |SMD| reduced from 0.973 to 0.167 under LR, 0.177 under BART, and 0.224 under GBM, respectively), indicating that observed differences between groups were effectively reduced.

Among retained estimators, results were consistent in both direction and magnitude. The LR-based ATT was -0.185 (SE = 0.028, 95% CI [-0.250, -0.147]), and BART yielded a similar estimate of -0.191 (SE = 0.029, 95% CI [-0.256, -0.149]). Although GBM produced a negative estimate, it was excluded due to instability under bootstrap resampling. Sensitivity analyses indicated that these negative effects were robust to potential unobserved confounding. These results suggest that, after adjusting for prior knowledge and observed covariates, students who requested explanations were less likely to correctly answer the subsequent problem than comparable students who did not seek help.

3.2 RQ2: Effects of On-Demand Explanations Compared to Answer-Only

We next compared explanation use to answer-only help ($n_{\text{control}} = 3659$, $n_{\text{treat}} = 821$). Common-support diagnostics indicated adequate overlap for LR, GBM, and BART, while RF and NN showed weaker or unstable support. Propensity score weighting improved covariate balance, with all retained estimators achieving acceptable post-weighting balance ($|SMD| \leq 0.25$) and most covariates showing low imbalance ($|SMD| < 0.10$).

Across all retained estimators, treatment effects were consistently near zero and not statistically significant. The LR-based ATT was 0.000 (SE = 0.012, 95% CI [-0.021, 0.026]), with similar near-zero estimates observed for GBM and BART. These findings indicate that, on average, requesting an explanation does not lead to improved short-term performance compared to simply viewing the answer.

3.3 RQ3: Heterogeneity of Explanation Effects by Student Engagement

We examined heterogeneity by focusing on an effort-based subset of students within the Explanation group ($n = 228$), representing moderate-to-high engagement.

Explanation (effort-based subset) vs. no help-seeking. Adequate common support was observed for LR and BART, and weighting improved covariate balance (max |SMD| reduced to 0.162 for LR and 0.146 for BART). Both estimators yielded statistically significant negative effects. The LR-based ATT was -0.139 (SE = 0.024, 95% CI [-0.179, -0.093]), and BART produced -0.184 (SE = 0.040, 95% CI [-0.249, -0.131]). Although these effects remain negative, they are smaller in magnitude compared to the full-sample

results, suggesting that greater engagement may partially mitigate the negative association observed in RQ1.

Explanation (effort-based subset) vs. answer-only. Common support was broader across estimators, and weighting achieved acceptable covariate balance. In contrast to the previous comparison, estimated effects were small but positive. The LR-based ATT was 0.048 (SE = 0.024, 95% CI [0.002, 0.095]), and BART yielded 0.057 (SE = 0.025, 95% CI [0.016, 0.100]). These findings indicate that, among more engaged students, explanations may provide modest benefits relative to answer-only support.

4. DISCUSSION AND FUTURE WORK

This study uses observational log data from ASSISTments to estimate the short-term causal effects of on-demand explanation use on subsequent problem performance. Methodologically, we integrate learner modeling with causal inference by incorporating DKT-derived skill mastery estimates as high-dimensional covariates in PSW models. This approach provides a richer adjustment for prior knowledge than commonly used proxies and illustrates how learner-model representations can strengthen causal analyses of platform log data [8, 10]. We also follow contemporary guidance for machine learning–based propensity score estimation, including overlap checks, balance diagnostics, estimator comparison, sensitivity analyses, and documentation of retained models [4, 8, 10]. Overall, these design choices illustrate how learner-model outputs and process data can strengthen post-hoc causal analyses of platform logs [23].

Across comparisons, explanation use was not associated with improved short-term performance on average and was instead linked to lower subsequent correctness when compared to students who did not seek help (RQ1). One plausible explanation for this pattern is the presence of unproductive help-seeking behaviors, such as gaming the system, that are not fully captured by the DKT-derived prior knowledge estimates. While DKT controls for students' historical performance at the skill level, it does not explicitly model behavioral tendencies related to strategic help use, such as rapidly requesting explanations to complete assignments rather than to support understanding. As a result, explanation use in this comparison may partially proxy for underlying gaming behavior, which has been shown to undermine learning outcomes in tutoring systems [1, 2]. In this sense, the estimated effects may reflect the impact of *clicking to access help and receiving an explanation as enacted in the platform*, rather than the effect of engaging with an explanation under conditions of productive use.

At the same time, alternative mechanisms may contribute to the observed negative average effects. Students in the no-help-seeking control group may engage more often in self-regulated problem solving, including persistence through errors, metacognitive monitoring, and strategy refinement. They may also seek support from external sources, such as peers, teachers, or other materials, which are not captured in platform data. These unobserved differences highlight an important limitation of log-based analyses and suggest that comparisons between help-seeking and non-help-seeking students may conflate the effects of instructional supports with broader differences in learning strategies and resource use.

In contrast, the explanation-versus-answer-only comparison (RQ2) yielded near-zero average effects across retained estimators, with confidence intervals spanning zero. This finding suggests that, for the target problem examined, viewing an explanation rather than only the final answer is associated with little to no immediate difference in performance on the subsequent problem. These near-zero estimates should not be interpreted as evidence that explanations lack educational value more broadly. Instead, they indicate that the effectiveness of explanations likely depends on how students engage with the support, rather than on the mere availability of help [8].

Results from the effort-based subset analysis (RQ3) further clarify this heterogeneity. When the explanation subgroup with moderate-to-higher adjusted time-on-task was compared to no-help-seeking controls, estimated effects remained negative, but with reduced magnitude. When the same effort-based subset was compared to answer-only students, estimated effects were small and positive. These contrasts suggest that explanation use does not operate as a uniformly beneficial treatment. Instead, outcomes vary with students' engagement patterns and with the counterfactual baseline. From a design perspective, these findings motivate platform features that better distinguish sense-making help use from rapid answer-seeking and that scaffold students toward more constructive engagement with explanations.

Several limitations remain. First, although we control for prior knowledge using DKT and include log-based engagement measures, we do not directly observe other learner characteristics such as motivation, metacognition, or affect. Second, the analysis focuses on a single problem and performance on the next problem, which may limit generalizability to other content areas or longer learning sequences. Third, although we examine heterogeneity using an effort-based proxy, engagement is likely multi-dimensional and may not be fully captured by time-on-task alone. With that, future work should extend this approach by incorporating richer measures of student behavior, including finer-grained indicators of self-regulated learning. In addition, applying this framework across multiple problems would help clarify the longer-term effects of explanation use.

5. CONCLUSION

This study demonstrates how learner-model representations and process data can be integrated into a rigorous quasi-experimental framework to estimate causal effects from observational digital learning platform logs. By incorporating Deep Knowledge Tracing–based skill mastery estimates as high-dimensional confounding controls within propensity score weighting, the approach extends common EDM practice and supports more transparent and principled causal inference. Applied to on-demand explanation use in ASSISTments, the findings show that explanations do not yield uniform short-term performance benefits and that their effects depend on students' engagement and help-seeking behaviors. Overall, these results demonstrate the importance of evaluating instructional supports as they are enacted in real learning contexts and highlight the methodological value of combining learner modeling with causal inference to study heterogeneous effects in educational data.

ABSTRACT

Being trained to competently use an ultrasound device typically takes a few years of training, and access to training programs is limited. With the rapid advancements being made in the field of machine learning, researchers are exploring ways to bridge this gap by developing AI-powered systems that can quickly upskill ultrasound novices. These systems have been shown to improve novice performance in the short term, but it is unclear if they are truly upskilling their users. It's possible that users of such systems are overrelying on the guidance that they provide, placing a hurdle in their path towards mastering the necessary skills to become competent sonographers. I believe that it's important to keep overreliance in mind when developing a system for AI-guided ultrasound, since it could potentially have the opposite effect and ultimately decrease the pool of competent sonographers in the long run. I plan to explore the cutting edge of the field to see what tools we have at our disposal, in particular, I have found world modeling and learning latent action spaces to be an exciting direction that could be applied to this problem. The generalizability of world modeling and the ability to learn a latent action space can be utilized to create an agent that imitates and aligns with the actions that professional ultrasound instructors take during traditional training programs. Ideally, such an agent could reduce the overreliance problem by performing actions that are conducive to learning and is not constantly giving away "correct answers" to every problem a sonogorapher trainee encounters during hands-on exercises.

Keywords

Ultrasound, AI-guidance, Overreliance, Latent Actions, World Modeling

1. PROBLEM INTRODUCTION

Point-of-care ultrasound (POCUS) has become a powerful tool in the arsenal of medical practitioners thanks to decades of innovation and miniaturization, donning the title of the "new stethoscope" [6, 25]. Despite it's demonstrated value and importance in modern medicine, becoming trained in the use of an ultrasound device is costly and difficult. Introducing ultrasound training early in a medical professionals career, such as in their undergraduate studies, has shown to pay off [24]. However, early career ultrasound training is limited by equipment costs, lack of faculty funding, and decisions over how to fit ultrasound training into an already packed undergraduate curriculum. As the demand for competent sonographers increases, utilizing AI to guide and teach early-career medical practitioners and ultrasound novices appears to be a promising direction towards addressing these shortcomings

1.1 Alternative Approaches to Teaching Ultrasound

Less conventional approaches to teaching the usage of an ultrasound device have been proposed to increase access to hands-on practice. [4] developed a system that tracked the position of a probe on a manikin, and a monitor would display ultrasound images collected from real patients based on the probe's position. [28] developed the Perk Tutor system, which provided visualizations and assistance for learning ultrasound-guided needle insertions. A follow-up study with Perk Tutor showed that undergraduate students that practiced with it had improved performance compared to a control group afterwards in a test without the Perk Tutor assistance [18]. [15] developed a similar system to Perk Tutor for ultrasound-guided needle insertions and found improved novice performance in certain cases, however they did not investigate if performance persisted when not using the guidance system. While these studies show promising results, one study has shown that fully self-directed ultrasound training with simulation software is insufficient [19]. One work developed a serious game, where the player scans boxes in a toy factory, to help with spatially understanding ultrasound [8]. Mixed reality has also been used to develop a sophisticated ultrasound teaching tool [29].

1.2 AI Ultrasound Guidance

Much work has been done in the last decade to leverage AI to aid in ultrasound scans, including assistance in scan plane acquisition and detection of anatomy within the ultrasound image. [5] developed a CNN model for obstetric ultrasounds to detect standard planes and localize anatomy. [9] Learns from experts performing echocardiograms by training a model to predict the next rotational movement of the ultrasound probe that aligns with a desirable scan plane of the heart. Further work expanded on this and trained a model

on expert eye-gaze, indicating to a novice sonographer where they should be looking at in an ultrasound image during a scan [20]. Reinforcement learning has been used to predict movements toward the desired scan plane by collecting ultrasound scans in such a way that allows for offline training [21].

World modeling techniques [3, 13] have been used to perform probe movement guidance [31, 14] by making good use of unlabeled data. However, this task necessitates often expensive equipment such as robot arms or optical tracking systems to obtain accurate 6D poses of the ultrasound probe during scanning. [9] makes use of an inertial measurement unit (IMU) device, which tends to be cheaper, but noise in the accelerometer makes translational data unusable and thus is only able to predict rotational adjustments to the probe.

1.3 Novice Performance with AI Guidance

AI-guided ultrasound systems that provide probe position guidance [17, 22] and segmented anatomy overlays [7] have been shown to improve novice performance. However, these works do not investigate if these methods of AI guidance facilitate long-term learning or induce overreliance. Although these systems have demonstrated performance improvement in novices, is it enough to fully address the shortage of trained sonographers? If overreliance proves to be an issue, then that would be concerning towards the long term development of skills [16]. I propose that to avoid overreliance on AI guidance, the system should try to closely align to traditional ultrasound training that happens during hands-on practice with volunteers or phantoms.

2. PROPOSED SOLUTION

Developing an AI guidance system that teaches sonography to novices on par with traditional instruction requires the system to understand what types of actions and behaviors (verbal, gestures, etc.) that traditional ultrasound instructors display during hands-on exercises. Existing work has introduced and analyzed datasets containing teacher actions and behavior in classroom settings [1, 33, 26, 11, 23]. However, similar datasets that label teacher behavior and actions for ultrasound instructors do not exist. Work has been done to wholistically represent the actions that sonographers take with the aim of improving sonography education [10], which can be useful in informing dataset curation and possible actions, but these could be different than the actions instructors take. I propose that curating a dataset of instructors guiding students through an ultrasound scanning procedure and annotating relevant actions is the penultimate step towards a guidance system that aligns with traditional ultrasound training.

A promising line of research that has recently picked up steam is in latent action modeling [12, 32, 30, 27], which seeks to learn possible actions from a dataset and represent them in latent space. Difficulties with privacy and costs immediately arise when collecting data of ultrasound instruction (e.g. one-on-one scanning sessions with a patient, sonography student, and an instructor), and labeling such a dataset with appropriate actions adds another layer of costs. These problems in data collection motivate a self-supervised approach towards learning a useful action space for the task of modeling actions that sonogrpahy make. Moreover, pretraining on web-scale data via world modeling to learn a rich action space from unrelated tasks [12] could be frutiful, since certain generic actions may transfer (such as pointing, or verbally indicating mistakes). Models trained in such a way, such as VJEPA2 [2], have demonstrated excellent sample efficiency on downstream tasks. Therefore, perhaps only a relatively small amount of ultrasound instructor action-labeled data would be enough to fine tune a powerful model. This would be the ultimate step of the proposed solution.

3. IMPACT

I anticipate that this research will provide insights to the benefits and shortcomings in applying world modeling and latent action space modeling to education, but more specifically to the domain of hands-on ultrasound training. Developing an action-labeled dataset for ultrasound instruction is also critical, as it can directly impact the ability of the model to derive appropriate representations of the instructor actions that are actually taking place during such training.

Astronauts' Cognitive Mapping: Evolving Identity through the Chronospatial Frontiers

Ginger[1] and Joo Young Park[1]
[1]Florida Institute of Technology
chenj2021@my.fit.edu

ABSTRACT
This research aims to construct a theoretical model of the cognitive maps contributing to astronauts' academic and professional success. By integrating Interpretative Phenomenological Analysis (IPA) and grounded theory (GT) to identify in-depth sensemaking as well as philosophical patterns within key factors, the researcher conducted nine semi-structured interviews to deepen the inquiry into astronauts' life-long narratives. The study introduces an original cognitive-mapping model comprising three interlocking systems: the chronosystem, ecosystem, and identity system. It explores how astronauts define pivotal moments, perceive environments, and establish self-identity to succeed in academic study and career development.

To address the analytical challenges of large-scale qualitative data, this study applies a human–AI collaborative approach, through which 92 axial categories and 20 selective themes were identified. Three original frameworks—Heavenly Hour, Terrain Triumph, and Human Harmony—were established, alongside two substantive theories and one emerging middle-range theoretical proposition. The findings further suggest a bicameral theorizing model for human–AI qualitative analysis, in which human interpretive depth and AI-enabled analytical scale converge to support complementary forms of meaning-making and theory construction. To operationalize this process, the researcher developed the GOLDEN Framework, a six-step methodology for ethical and reflexive human–AI collaboration designed to support rigorous analysis of large-scale qualitative data and strengthen synergistic human–AI learning.

Keywords
Cognitive mapping, Interpretative Phenomenology Analysis, Grounded Theory, Human-AI Collaboration, Qualitative analysis

1. INTRODUCTION
The contemporary challenges including the biological weapon threats [1, 2], environmental crises, geopolitical tensions [3], and technological shifts driven by AI have contributed to an education crisis [4]: how to guide the current and future generations towards success? Astronauts, as modern-day way finders, with their life experiences and informed decision-making could delineate a cognitive map [5] for navigating educational and social landscapes in an era marked by unprecedented uncertainty. This study examines how astronauts perceive pivotal moments, formative environments, and self-identity, focusing on revealing the underlying factors that enable them to excel in academic study and career development. Using a qualitative approach that combines IPA [6] and GT [7], while IPA grounds the inquiry in the richness of individual lived experience, GT provides the systematic scaffolding to build transferable conceptual patterns across cases, the researcher seeks the shared meanings and emergent conceptual patterns within their lived experience to address the three research questions: to have excelled in academic study and career development, 1) What are astronauts' pivotal moments? 2) What are the main environmental factors? 3) How do astronauts define their self-identity?

2. METHODS

2.1 Sampling, Participants, and Data
Purposive sampling method is chosen to conduct semi-structured interviews [8], which allows the deliberate selection of individuals with the specific criteria necessary to address the research questions. The sample consists of nine retired astronauts who have travelled to space. Four astronauts' lifelong partners also consented to join the project, helping the participant better recall details and strengthen the depth of the conversation by providing crucial relational context. The primary astronaut sample includes female (n=2) and male astronauts (n=7). The average age of total 13 participants (nine astronauts and four partners) is 76. All of the participants were given a pseudonym unless they explicitly gave the consent to use their real names.

A research facilitator supported the recording and transcribing with Voice Recorder & Notes Pro and Adobe Premium Pro for the six in-person interviews. The researcher applied Google Meets, Team Meeting to record and transcribe the three virtual interviews. The average time of each audio-recorded semi-structured interview is 2.56 hours, and the average word count of each transcript is 20,460. Along with the nine formal interviews, the researchers applied reflexive journals to analyze data [9].

2.2 Data Analysis
The researcher adopted an iterative human-AI approach to construct meaning not only accurately but also artistically [10], and developed the GOLDEN Framework, acronymed for Ground, Operate, Lead, Deepen, Ethics, and Nature, a six-step ethical and reflexive protocol for qualitative analysis. Figure 1 shows three types of AI tools structurally applied, and Table 1 demonstrates how to operate AI4People Principles across the GOLDEN stages [11]. Across all three works (Heaven Hour, Terrain Triumph, and Human Harmony), data saturation was assessed using theoretical saturation criteria [7] and then using design effect/effective sample

size framework [12], paired with Silverman's [13] data density principles. This dual quantitative–theoretical approach ensures saturation is justified both by demonstrated conceptual closure across axial and selective levels and by statistical sufficiency.

To enhance the credibility of the research, the synthesized member checking in addition to traditional member checking approaches was adopted [14]. As Spall [15] suggests, the researcher invited four experts with knowledge of the research but not participants provide a review of the data collection and analysis to ensure the absence of bias, adding to the study's validity. To further increase the study's trustworthiness, three external auditors from diverse professional backgrounds without knowledge of the study are invited to provide an unbiased examination of the findings, interpretations, and conclusions [16].

3. THEORETICAL BACKGROUND

Having identified the four stages of astronauts' mental representations, Suedfeld [17] proclaims that space psychology must undoubtedly maintain its concern with predicting, preventing, and countering adverse reactions. To truly understand what space exploration means to those who engage in it, it is necessary to look at how the explorers respond to challenges. This means that the early myths- the formative years of astronauts' experiences with deliberate decision making are not negligible. Thus, the research applies cognitive maps to seek key decision-making points through a whole-life approach to reflect on how personal needs are satisfied as well as personal values are realized over the life course [18].

3.1 Cognitive Mapping

Edward C. Tolman's pioneering work introduced the concept of cognitive maps - mental representations that individuals develop to understand and navigate their environments [5]. The researcher then integrates the western cognitive mapping theory and the Chinese ancient strategic thoughts to achieve success: Heaven, Earth, and Men.

3.2 Heavenly Hour, Terrain Triumph, Human Harmony (HTH Model)

Mencius (c. 372 – 289 B.C.) highlighted the superlative significance of humans in the trio relationship: tiān shí is inferior to terrain triumph, and dì lì is inferior to rén hé. This ideology reflecting the Chinese essential worldview of the interconnectedness of the divine trinity of the universe has been translated and applied in various fields by Western scholars. Lau [19] interpreted, "opportune times are not as good as advantageous terrain; advantageous terrain is not as good as harmonious people." Van Norden [20] simplified, "The timing is not as important as the terrain, and the terrain is not as important as having unity among the people." To keep the accuracy as well as fluency, the researcher translated with the simplest version, "Heavenly Hour matters. Terrain Triumph more. Human Harmony most."

Then the interview protocol was formulated based on the HTH model to explore astronauts' defining moments, formative environments, and self-identity. Compared to Piaget's learning stages theory [21] and Vygotsky's development of learning zones [22], the researcher gives voices to the participants to define their own terms to inform teaching methodologies and education policies for customized plans for each unique individual learner.

4. RESULTS

Through a rigorously iterative human-AI qualitative analysis from more than 8,751 open codes, the researcher selected 20 emergent themes and refined 92 axial categories across three original theoretical frameworks. Directed by Finlay's [23] "maps' of five variants of reflexive activities, the researcher found that comparative analysis of human-refined and AI-generated outcomes reveals a complementary relationship: human sensemaking provides interpretative depth, while algorithmic processing enables indispensable scalability. The findings indicate that human-AI synergistic workflows support effective model for high-volume textual analysis.

4.1 Heavenly Hour Framework and Theory

The Heavenly Hour framework encapsulates the five pivotal moments shaping astronauts' trajectories: spark-ling interest, honing transition, awakening passion, reaching fulfillment, and pledging commitment, acryonymed SHARP. Often honed through

military training or rigorous academic disciplines, astronauts demonstrate an exceptional ability to recognize and capitalize on opportune moments, reflecting their cognitive precision, time consciousness, and decisiveness. Figure 2 shows how the human- and AI-based coding result theoretical frameworks exhibiting greater interpretive complementarity in three dimensions.

• MONOLOOP astronauts: Top Tier forces dominate on a single path. Inner Compass is unwavering. Agency appears high because the path is clear.

• BILOOP astronauts: Middle Tier becomes critical because Inner Compass must reconcile two domains. Relational Scaffolding supports the dual commitment. Serendipity often determines which loop becomes primary.

• POLYLOOP astronauts: All seven Nexus forces operate at maximum complexity. Each loop generates its own Capital, Trajectory, and Crucibles, while the Inner Compass integrates across loops. This is where the Enabling Tier becomes most visible: navigating multiple loops requires both luck and deliberate choice.

```
DIMENSION 1: TRAJECTORY PATTERN (Lollipop Fractal)
How many study/career loops does the astronaut traverse?

  Monoloop    Biloop       Polyloop
     ○          ∞            ✿
  single     dual path    multiple
  trajectory  convergence  overlapping loops

DIMENSION 2: PIVOTAL MOMENTS (SHARP)
What phenomenological sequence marks each loop?

  S → H → A → R → P
  Spark  Hone  Awaken  Reach  Pledge
  (each loop contains its own SHARP sequence)

DIMENSION 3: FORCES (Nexus)
What 7 forces power each moment within each loop?

  Top:     Capital + Trajectory + Crucible     (56.7%)
  Middle:  Inner Compass + Rel. Scaffolding    (29.2%)
  Enabling: Serendipity + Agency               (13.1%)
```

Figure 2. Heavenly Hour Theoretical Alignment

4.2 Terrain Triumph and A Middle-Range Theoretical Proposition

The researcher upgraded Bronfenbrenner's ecological systems [24] into the ISEE Terrain Triumph framework. ISEE is acryonymed for four ecological systems: the ideological and cultural macrosystem (IDEAL), social and interpersonal mesosystem (SOAP), environment and physical exosystem (EPIC), and emotional and psychological microsystem (EMO). Each system comprises both catalysts and challenges, which yielded eight themes in Terrain Triumph, e.g. EPIC Challenge and EPIC Catalyst. This framework maps out the dynamic interplay between catalysts and their counterparts-challenges, revealing the nuanced progression of astronauts' diversified life stages.

Despite statistical evidenced pass for workability (Figure 3) and hypotheses tests [7] (Figure 4), the researcher suggests a middle-range theory with emerging patterns [25], tentatively termed Death Is Not the End of the Story (DINTEOTS), which characterizes how individuals transform adversity, loss, and challenges into sustained trajectories of growth and meaning-making.

4.3 Human Harmony Framework and Theory

Although the researcher's seven human-coded themes — acronymed as the iNSPIRE framework — diverge in nomenclature from the seven AI-generated themes, human-AI collaboration revealed a notable convergence of independently derived conceptual structures, lending empirical support to AI's socio-emotional attributes [26]. As illustrated in Figure 5, both codlings organize around a shared four-stratum architecture — 元 Core, 基 Foundation, 变 Dynamic, and 合 Integration — functioning as a common interpretive scaffold across 41 human axial categories (268 refined open codes) and 36 AI axial categories (1,145 initial open codes). AI-generated thematic functions of harmony aligned with the researcher's human-centered identity framework, yielding two complementary theoretical formulations: a researcher's reflective All-Mirror-in-One perspective emphasizing unity through mutual interpretation, and the AI-layered 4Strata model describing the operational dynamics of identity across multiple dimensions. This convergence demonstrates how distinct analytic pathways can arrive at shared higher-order abstractions. While human contributions provide philosophical depth and contextual nuance, AI enables empirical rigor through expansive coding, statistical saturation testing, theme-shift quantification, and convergence–divergence metrics.

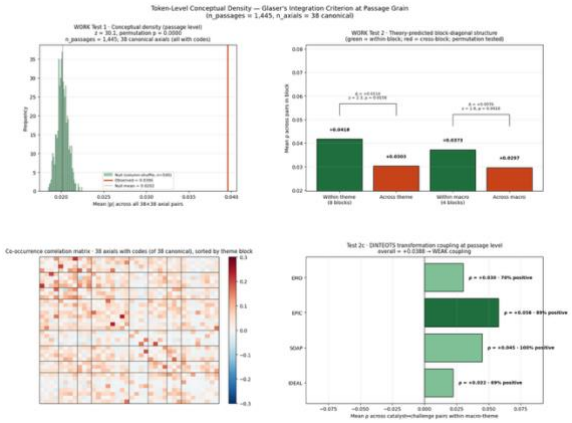

Figure 3. Terrain Triumph Work Test

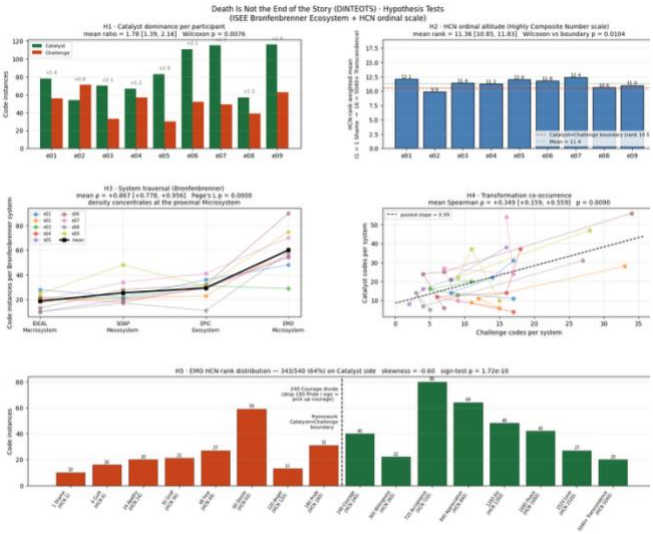

Figure 4. Terrain Triumph Hypotheses Testing

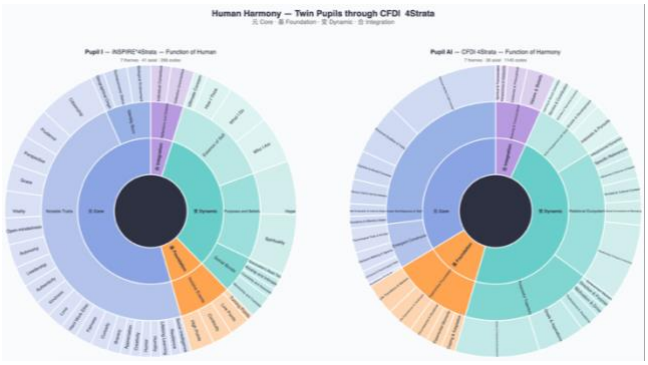

Figure 5. Human Harmony Frameworks: Comparative Sunburst Visualization of Human-Coded iNSPIRE*4Strata (Pupil I) and AI-Coded CFDI*4Strata (Pupil AI)

4.4 HTH Model and Bicameral Theorizing

Drawing on Jaynes's [27] foundational conception of the bicameral mind that cognition operates through two distinct yet interacting chambers, the researcher extends this metaphor into bicameral theorizing, a Human-AI qualitative analytic structure in which researcher-led (I + AI) and AI-surfaced (AI + I) reasoning function as complementary generative modes rather than interchangeable contributions. This bicameral architecture organizes the HTH Model across three frameworks — Heavenly Hour, Terrain Triumph, and Human Harmony — each partitioned into two epistemically distinct halves. The Structural/Locational half anchors identity in its situated, relational, and contextual dimensions, yielding the collaborative constructs Lollipop Fractal, Heart-Land, and All-Mirror-in-One grounded theories. The Transformational/Teleological half orients identity toward purpose, trajectory, and emergent meaning, producing AstroNexus, DINTEOTS, and 4Strata Navigation. This deliberate alternation of analytic authorship across halves reflects a principled division of generative labor.

The overall bicameral structure — structural grounding paired with teleological projection — mirrors the dual functions of identity itself: where one is and where one is becoming. Importantly, the distribution of theorizing labor is not fixed but contingent upon the researcher's personality, cognitive dispositions, and analytic capabilities. In this study, the researcher's inclination toward structural and locational reasoning anchored the first half of each framework, while AI's complementary teleological capacity completed the theorizing arc in Heavenly Hour and Human Harmony. Terrain Triumph, however, illustrates a different configuration: one in which the researcher independently drove the theoretical construction from the ground up, yet AI's contribution to statistical validation through procedures such as the Work test and hypothesis testing remained integral to substantiating its middle-range theory claim. This suggests that bicameral theorizing functions less as a rigid division of labor and more as a dynamic, researcher-sensitive scaffold whose outcomes reflect the unique epistemic posture each inquirer brings to the analytic encounter.

Table 2. Bicameral Theorizing across HTH Model

Framework	Structural/ Locational Half	Transformational/ Teleological Half
Heavenly Hour	Lollipop Fractal (I + AI)	AstroNexus (AI + I)
Terrain Triumph	Heart-Land (I + AI)	DINTEOTS (I + AI)
Human Harmony	All-Mirror-in-One (I + AI)	4Strata Navigation (AI + I)

5. DISCUSSION

Resonating with Silver and Lewins's emphasis on engaging with emerging technology for qualitative analysis [28], this study highlights the irreversibility and uncertainty inherent in intensive analytical processes. It remains an open question whether comparable AI-generated outcomes would have emerged without the researcher's prior extensive validation of over 8,751 open codes and the subsequent development of theoretical frameworks and grounded theories.

Extending ongoing debates on data saturation [29], this study argues that saturation can be reexamined in light of AI-supported analysis through indicators such as information power, data density comparison, effective sample size, empirical saturation evidence, and methodological precedent. Meanwhile, critical questions remain: to what extent can human-AI collaboration reproduce - or transform - the trajectories of qualitative sensemaking?

In summary, this study underscores the importance of human-first iterative engagement prior to AI integration to preserve methodological rigor and to mitigate risks associated with irreversible analytical decisions [30]. Such considerations point toward a broader rethinking of how human agency, technological augmentation, and epistemic responsibility co-evolve in the future of data-intensive research [31].

ABSTRACT

Multimodal large language models (MLLMs) are increasingly proposed for tutoring, feedback, and other educational uses, yet they remain brittle on mathematics problems that require interpreting diagrams, graphs, number lines, and other figures. This dissertation investigates whether many of these failures are fundamentally representational: models may have the mathematical knowledge needed to solve a problem, but fail because the visual information is not encoded in a sufficiently faithful form for downstream reasoning. To address this challenge, I study alternative representations of image-dependent mathematical content, including high-quality alt-text, structured textual descriptions, and executable Python reconstructions of the original figure. I first analyze difficult image-dependent middle-school mathematics problems to identify recurring visual bottlenecks in MLLM performance. I then evaluate whether alternative representations improve not only problem solving, but also educationally meaningful tasks such as hint generation, explanation, scaffolding, accessibility support, and related-problem creation. The dissertation contributes both an empirical account of representational failure in multimodal educational AI and a design framework for making visual mathematical content more usable in learning environments.

Keywords

multimodal large language models, mathematics education, visual representations, accessibility, educational AI

1. INTRODUCTION

Multimodal large language models (MLLMs) are increasingly being explored for tutoring, feedback, problem solving, and other educational applications. In mathematics education, however, many tasks depend on diagrams, graphs, geometric figures, tables, and other visuals that provide essential problem context. These are not simply text questions with accompanying illustrations; rather, the visual representation often contains information required to determine the correct answer or construct a valid solution. Such visually grounded tasks also arise in classroom-authentic tutoring and assessment settings, including platforms such as ASSISTments [3].

This challenge is especially important for educational data mining and AI in education because model success on visually grounded tasks depends on more than symbolic reasoning alone. A model may appear mathematically capable while still failing to count objects accurately, read a scale, bind labels to the correct visual elements, or preserve spatial relations needed for reasoning. As a result, strong performance on broad multimodal benchmarks can obscure weaknesses that matter in authentic learning environments [4]. Recent work on authentic middle-school image-dependent mathematics suggests that such failures are often driven by visual misreading rather than symbolic mathematics alone [2].

My dissertation is motivated by the hypothesis that many of these failures are fundamentally representational. In other words, the model may possess the mathematical reasoning required once the relevant information is available, but fail because the original image is not transformed into a sufficiently faithful internal or external representation for downstream reasoning. This dissertation therefore asks whether alternative representations of visual mathematical content can make image-dependent mathematics more usable for MLLMs in educational settings. Rather than treating the original image as the only viable input, I investigate forms such as high-quality alt-text, structured textual descriptions, and executable Python scripts that reconstruct the figure while preserving its mathematical structure.

2. PROBLEM AND RESEARCH GAP

MLLMs have become a central topic in educational technology research, with growing interest in their use for tutoring, automated feedback, accessibility, and content generation. At the same time, prior work in mathematics education and the learning sciences has shown that representations are not incidental to learning; they shape interpretation, inference, and strategy selection [1, 5]. This makes image-dependent mathematics an important testbed for educational AI.

Existing multimodal work often focuses on benchmark accuracy or broad demonstrations of capability [4]. While this work is valuable, it does not fully explain why visually grounded mathematics problems remain difficult in authentic educational settings, especially when success depends on

Ethan Croteau, and Neil Heffernan. Beyond Seeing: Alternative Representations for Image-Dependent Mathematics. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) precise visual interpretation. In such cases, failure may reflect not only reasoning limitations but also bottlenecks in how task-relevant visual information is represented.

A second gap is that most work treats the original image as the primary or only form of visual input. In educational systems, however, the same mathematical content can often be expressed in multiple forms. A diagram may be represented as alt-text, as a structured description of entities and relations, or as an executable program that reconstructs the figure. These alternatives may preserve different aspects of the original content and may vary in how well they support reasoning, explanation, accessibility, and content generation. Accessibility guidance emphasizes that such alternatives must preserve task-relevant structure, not merely summarize appearance [6, 7]. Despite this promise, representation choice has not been studied systematically for image-dependent mathematics in educational contexts.

3. RESEARCH QUESTIONS AND THEORETICAL FRAMING

The dissertation is organized around three questions:

RQ1: What kinds of image-dependent mathematics problems remain especially difficult for MLLMs, and what recurring visual bottlenecks contribute to these failures?

RQ2: To what extent can alternative representations of visual mathematical content improve MLLM understanding and problem solving on image-dependent tasks?

RQ3: Which forms of alternative representation are most useful for downstream educational tasks such as hint generation, explanation, scaffolding, accessibility support, and the creation of related practice problems?

These questions reflect a dissertation arc that moves from *diagnosis* to *intervention* to *educational application*. The central theoretical claim is that representation is not merely a delivery format for visual information; it is part of the mechanism by which a model can or cannot reason successfully about a task. Accordingly, this dissertation treats alternative representation as both an analytic lens for explaining multimodal failure and a design space for building more useful educational AI systems.

4. CURRENT PROGRESS

A substantial portion of the dissertation's diagnostic phase is already complete. Earlier work on authentic middle-school mathematics problems in which the image is required for solving showed that even strong contemporary MLLMs remain brittle when the figure contains task-critical information not recoverable from text alone. Across repeated evaluations with and without the figure, these studies suggested that visual misreading is a dominant failure mode, with recurring errors involving counting, measurement, label binding, and geometric relation extraction.

This prior result motivates the dissertation's shift from diagnosing image-dependent failure to studying representation as an intervention. Rather than viewing each failure only as evidence of insufficient model capability, I ask whether the same visual information can be expressed in forms that are more accessible to the model while remaining faithful to the underlying mathematics. To explore this possibility, I conducted early experiments using prompting to generate Python scripts that reconstruct selected images from difficult mathematics problems. These scripts, typically implemented with plotting or drawing libraries, serve as executable representations of the original figure. Unlike a static image, they can be inspected, edited, parameterized, and potentially reused for multiple educational purposes. Building on these experiments, I have also begun implementing an early-stage web prototype that converts structured math-task inputs into schema-constrained visual specifications, deterministic scene representations, executable Matplotlib code, and SVG outputs. The prototype logs intermediate artifacts and run-level metadata, enabling inspection and comparison of alternative representations, but it should currently be understood as research infrastructure rather than as a fully evaluated educational intervention.

These early experiments suggest that executable representations may have value beyond answer production. Because they expose the structure of a figure in a machine-readable and human-interpretable form, they may support hint generation, explanation, scaffolding, and the creation of related-but-not-identical problems. Likewise, alt-text and structured descriptions may improve accessibility for learners who cannot fully access the original image while also providing models with more explicit task-relevant information.

5. PROPOSED METHODOLOGY

The next phase of the dissertation will systematically compare multiple representations of the same image-dependent mathematical content. I currently anticipate studying at least four representation conditions: (1) the original image, (2) high-quality alt-text, (3) structured textual descriptions designed to preserve task-relevant visual relations, and (4) executable Python reconstructions of the original figure. Hybrid conditions that combine these forms may also be explored.

These representations will be evaluated across several educationally meaningful tasks. The first is direct problem solving on image-dependent mathematics items. Here I will measure whether alternative representations improve model performance and reduce specific types of visual failure. The second is hint and explanation generation, where the goal is not simply to produce a correct answer but to generate support that is instructionally useful and grounded in the relevant visual structure. The third is scaffolding and accessibility support, including whether alternative representations help make visual mathematical information more understandable to both models and learners. The fourth is related-problem generation, where executable or structured representations may enable the creation of new problems that are similar in concept but not identical in surface form.

Methodologically, I plan to combine quantitative evaluation with qualitative analysis. Quantitative measures will include problem-solving accuracy, consistency across repeated trials, and performance differences across representation conditions. Qualitative analyses will examine which visual bottlenecks persist, which are reduced, and what kinds of down-

stream outputs become more educationally useful under alternative representations. For generative tasks such as hints or related-problem creation, expert review may also be used to assess mathematical fidelity, pedagogical usefulness, and alignment with the intended concept.

6. EXPECTED CONTRIBUTIONS AND RELEVANCE TO EDM

This dissertation aims to contribute at three levels. First, it will provide an empirical characterization of the visual bottlenecks that make some image-dependent mathematics problems especially difficult for MLLMs. Second, it will contribute a methodological framework for studying alternative representations of visual mathematical content and their effects on downstream reasoning. Third, it will offer practical guidance for educational applications, including tutoring, accessibility support, grounded explanation, and content generation.

The work is relevant to EDM in several ways. It studies how representational choices shape model behavior on authentic educational tasks; it addresses human factors and explainability by examining why models fail on visually grounded items; and it connects to the broader EDM interest in comparing human and artificial intelligence on learning-relevant tasks. More broadly, the dissertation is intended to speak to both learning sciences and computer science perspectives by combining attention to representational meaning, learner accessibility, and instructional usefulness with rigorous evaluation of model performance.

7. FEEDBACK SOUGHT

I would especially value feedback in three areas. First, I seek guidance on how best to position the dissertation's central contribution: as a study of multimodal failure, a study of alternative representation, or a broader effort to support educational uses of visual mathematical content. Second, I seek feedback on the design of the representation comparisons, including which representation conditions and evaluation tasks should be prioritized for the dissertation. Third, I would value advice on how to strengthen the link between EDM, AIED, and learning sciences perspectives when evaluating educational usefulness beyond answer accuracy.

Overall, this dissertation aims to understand why "seeing" is often not enough for current MLLMs on image-dependent mathematics, and how alternative representations may help bridge that gap in ways that are meaningful for learners, educators, and educational AI systems.

ABSTRACT

Large language models (LLMs) are widely used for tutoring, feedback generation, and content creation, but their broad pretraining makes them hard to constrain and poor substitutes for controllable learners. Educational systems often require inspectable and editable knowledge states: educators want to know what a system assumes the learner knows, and learners benefit when the system can justify actions in terms of explicit skills, misconceptions, and strategies. Inspired by cognitive architectures, we propose Cognitive Agent Compilation (CAC), a framework that uses a strong teacher LLM to compile problem-solving knowledge into an explicit target agent. CAC separates (i) knowledge representation, (ii) problem-solving policy, and (iii) verification and update rules, with the goal of making bounded problem solving more inspectable and editable in educational settings. We present an early proof of concept implemented with Small Language Models that surfaces key design trade-offs, particularly between explicit control and scalable generalization, and positions CAC as an initial step toward bounded-knowledge AI for educational applications.

Doctoral Consortium Application: Exploring Temporal Dynamics Underlying Eye Gaze, EEG, and Text Characteristics during Naturalistic Reading with Multi-Level Vector Autoregression

Megan Caruso
University of Colorado Boulder
Boulder, CO, USA
Megan.Caruso@colorado.edu

ABSTRACT

Understanding how learning unfolds moment-to-moment remains a central challenge in capturing real-time learning processes. Much of the field has focused on aggregated behavioral signals or prediction of outcomes, often overlooking the fine-grained temporal dynamics through which learning processes emerge. This work introduces a multimodal, temporally explicit framework for modeling reading comprehension by integrating eye tracking, EEG, and textual features at the level of individual fixations during naturalistic reading.

We analyzed data from 116 participants reading five long expository texts while eye movements and EEG were recorded concurrently. We then constructed fixation-level, multivariate time series that included gaze (fixation duration), neural responses (fixation-related potentials), and lexical properties (surprisal and word frequency). We applied multivariate vector autoregression (mlVAR) to model how these signals unfold over time, both within fixations (contemporaneous) and across fixations. We also examined how comprehension, reading time, prior knowledge, and mind wandering covary with network connectivity.

Across models, robust lexical-gaze relationships were observed, with surprisal positively associated with fixation duration and word frequency negatively associated with fixation duration, both within and across fixations. These patterns extend classic findings from reading research into a temporal, multivariate setting. Neural associations were more sensitive to modeling choices, suggesting that brain-behavior coupling may depend on how temporal structure is represented. At the participant level, comprehension and reading time were associated with differences in contemporaneous network connectivity, indicating that variation in learning outcomes corresponds to differences in multimodal coordination.

Overall, this work positions temporal network modeling as a promising direction. By integrating multimodal signals at a fine temporal scale in naturalistic settings, it provides a framework for studying learning as a dynamic, evolving process rather than a static outcome. Beyond reading comprehension. This approach offers a generalizable methodology for modeling temporal dependencies across modalities in a wide range of educational contexts.

ABSTRACT

The prevalence of online reading platforms has surged along with improvements to automatic speech recognition (ASR) systems. These platforms facilitate personalized reading instruction, but like all learning systems, work best when students find them engaging. The Educational Data Mining (EDM) community has made great efforts to detect student engagement, but these efforts have largely been confined to school and lab environments without intentionally including neurodiverse populations. In the present study, we evaluate engagement levels in children with attention deficit hyperactivity disorder (ADHD, n=55), autism (n=38), both autism and ADHD (n=38) and with no known clinical diagnoses (n=22) as they interact with a digital literacy learning system from their homes. Engagement was measured using parent report, and acoustic features were extracted from audio recordings of the students while they interacted with the Amira literacy learning system. Our results indicate that acoustic measures related to temporal features, pitch, and vocal quality are related to engagement levels across all clinical groups. We also identify key temporal features that vary across different clinical groups. These findings demonstrate the validity of using non-invasive acoustic features to measure engagement levels during reading comprehension tasks at home. However, interaction effects also highlight the importance of taking into account children's clinical diagnosis when measuring engagement.

1. INTRODUCTION

Digital reading platforms have emerged as a promising way to provide personalized literacy instruction to students, both at home and at school. These platforms guide the student through level-appropriate passages where they can read text out loud, receive real-time interventions, and respond to reading comprehension questions[69]. Compared to traditional instruction, Intelligent tutoring systems (ITSs) for reading can even produce larger learning gains [65, 70], even among students with learning differences that sometimes interfere with reading comprehension, such as Autism Spectrum Disorder (ASD) [39]. However, meta-reviews of literacy applications have demonstrated that they are most effective when (1) the systems are highly interactive and (2) children use them with higher intensity (at least 75 minutes per week) and duration (at least 3 months) [39, 69, 70]. This leads to a direct need to understand how engaged students are with a platform in order to provide effective instruction and keep them coming back for regular sessions.

Reading engagement is often defined as the student's active involvement with reading [32], and it is sometimes distinguished from motivation by considering motivation as a mindset that is necessary in order to deeply engage with reading [2]. Although exact definitions of reading engagement vary, it is often described as including cognitive, affective, and behavioral dimensions [41]. Reading engagement is not only indicative of children's enjoyment, but is also linked to improved reading abilities and reading comprehension [6, 31, 41, 63].

Despite an abundance of research on engagement measures, there is no standardized method for measuring student's engagement with online reading platforms. Some conversational agent based literacy tools operationalize verbal engagement in terms of child response length [33] or semantic features including topic relevance and intelligibility [68]. However, these measures are proxies for the actual construct, which is likely to involve a range of cognitive, behavioral, and affective experiences [26]. Moreover, they do not account for key acoustic elements, including those that may be more in-

dicative of a students' affective experience with the reading activity [44].

In this study, we explore the use of acoustic features to detect reading engagement among neurodivergent students with different clinical diagnoses, including Autism and Attention Deficit Hyperactivity Disorder (ADHD). We examine the use of acoustic features as they can be easily extracted by voice-based reading software without the use of specialized equipment that may be difficult to acquire for use in either the home or classroom. We evaluate the interaction between clinical diagnosis and engagement levels by analyzing acoustic features that indicate voice quality, speaking rates, and prosody, and which have been associated with engagement in prior research [34, 44].

To our knowledge, this is one of the first studies to focus on understanding which acoustic features most effectively model engagement during digital reading instruction, and one of the first in the EDM community to consider how clinical diagnoses might affect those modeling efforts. Our results indicate that temporal acoustic features are robust indicators of engagement across groups in our study, but other acoustic features (e.g., variation of voiced segment length) are diagnosis-sensitive. With this work, we aim to contribute to a better understanding of how engagement manifests differently in diverse populations of learners while also putting forward tools to help detect these differences, provide personalized support, and ultimately improve outcomes.

2. BACKGROUND AND RELATED WORK

Research on student engagement defines it across many dimensions, including behavioral, emotional, and cognitive domains [26]. Real-time models of student engagement have become a common way for researchers in the Educational Data Mining community to study engagement at scale, including both affective engagement and cognitive engagement. Such models have been trained on a variety of label types, including those produced from text-based video [76], video data [10, 36], speech [71, 44] physiological signals including skin conductance data [12, 77], posture data [56], and self-report [74, 18]; and from classroom observations [5, 50].

Much of this work has focused on affective engagement [13], although behavioral and cognitive engagement [30, 42] are also modeled. Such models have been particularly important for researchers studying affect dynamics [20, 51]. They have also been useful for making short-term and long-term predictions about student learning outcomes [27]. However, given the rich history of definitions involved with studying student engagement in the broader research community [26], the EDM community continues to explore novel ways to capture this construct.

2.1 Detecting Reading Engagement in Learning Systems at Home

One particularly difficult challenge in this space is appropriately creating high quality engagement labels for students who use learning software at home. Many sensors used to detect engagement can be highly invasive (e.g., video), while others are difficult to use in the home environment (e.g., posture sensors). Meanwhile, interaction-based detectors [50] rely on classroom observation or self-report data to provide the labels. Although these detectors can certainly be applied to students in the home environment, it is difficult to verify whether detectors trained on labels from a classroom environment would generalize to students' home environments. Additionally, self-reports are susceptible to self-presentation effects and to differences in students' ability to gauge their own level of participation [21, 28].

A few studies have sought to leverage measures that could be more easily collected in a home environment. For example, models based on student response times leverage item response theory to distinguish between engaged and disengaged students in online settings [7, 35]. These could be used in home environments, even if they might need to be renormed for different clinical populations. Another approach is to measure student talk time while engaging with an online tutor[17]. Some existing reading software measures verbal engagement based on the number of turns with a conversational agent or word counts [33]. Xu et al. [68] evaluated the nuances of children's responses to comprehension conversations asked by conversational agents versus humans via five aspects of verbal engagement: lexical diversity, intelligibility, productivity, topic relevance, and accuracy [66, 64]. Similarly, Gorgun et al. leveraged linguistic features in online discussion posts to estimate engagement based on third-party manual coding [30]. Their scheme defined four attributes of cognitive engagement: interactive, constructive, active, and social.

In addition to semantic-based engagement features, some researchers have explored the use of acoustic features in the online setting. Litman et al. [44] evaluated prosodic cues of disengagement and uncertainty while students engaged with a physics tutor. Their research demonstrated that when students are disengaged, they respond significantly more slowly than engaged students. Disengaged students were also found to have lower maximum and mean pitch values than their engaged peers. Furthermore, disengaged students demonstrated more steady pitch values as well as lower levels of energy. Our study builds upon these findings, with the intention of exploring whether they apply to non-neurotypical learners.

2.2 Reading Engagement in Individuals with ASD and ADHD

As our ability to detect engagement in online settings has advanced, there have been increasing calls for better understanding for a more diverse range of learners [52], and subsequent research has shown that additional demographic information can improve models. For example, Karumbaiah et al. [38], shows that some behavioral engagement measures (i.e., help-seeking) are better understood when school-level demographics are taken into account. Likewise, other research has shown that we can improve our models of mind-wandering by accounting for neurodivergence [67].

Accounting for clinical diagnoses in engagement research is particularly important since certain conditions are characterized by developmental challenges that begin to emerge during early childhood and impact multiple life domains (e.g. school, home) across the lifespan [49]. These increasingly prevalent conditions are characterized by factors that

Table 1: Demographic and clinical characteristics of participant groups. Number of activities signifies the number of comprehension conversations that were included from each participant subset.

Clinical Group	Mean Age (SD)	Male	Female	Ethnicity	Activities
ADHD	8.527 (1.386)	35	20	Not Hispanic or Latino (48)	305
				Hispanic or Latino (7)	
ASD	8.345 (1.632)	14	15	Not Hispanic or Latino (22)	129
				Hispanic or Latino (7)	
ASD+ADHD	8.316 (0.904)	22	16	Not Hispanic or Latino (34)	169
				Hispanic or Latino (4)	
Not ASD or ADHD	8.409 (1.054)	11	11	Not Hispanic or Latino (18)	103
				Hispanic or Latino (4)	
Overall	8.417 (1.276)	82	62	Not Hispanic or Latino (122)	709
				Hispanic or Latino (22)	

could interfere with our measurement of student engagement [14]. For example, individuals with Autism Spectrum Disorder (ASD) face persistent challenges in social communication, as well as restricted or repetitive patterns of behaviors, interests, and activities [4]. Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental condition diagnosed in about 1 in 11 (10.5%) of U.S. school-aged children [15] and is distinguished by persistent patterns of inattention and/or hyperactivity-impulsivity. While autism and ADHD are distinct neurodevelopmental conditions, they frequently co-occur. 50-70% of people with ASD meet diagnostic criteria for ADHD [58] and 12.5% of individuals with ADHD meet diagnostic criteria for ASD [73]. This co-occurrence (colloquially referred to as AuDHD) could result in additional nuances in learning behavior that would further complicate accurate measurement of engagement in this population.

Although ASD and ADHD often co-occur with disabilities that directly impair reading skills (e.g. dyslexia; [11]), various clinical features specific to ASD and ADHD can also contribute to challenges with reading engagement and comprehension for children with either condition. Specifically, impairments in social communication, word recognition, and oral language may compromise many autistic children's reading comprehension skills [57, 46, 40]. Furthermore, some early autistic readers exhibit a striking discrepancy between their reading comprehension and word recognition skills such that their reading comprehension skills lag behind their growing proficiency in word recognition [16]. Reading comprehension may also pose difficulty for children with ADHD. Working memory impairments that are characteristic of ADHD can constrain reading comprehension and limit children's ability to recall central ideas from text directly after reading it [47]. Additionally, on average, children with ASD and/or ADHD may struggle to maintain sustained attention on tasks they are not interested in or motivated to complete. This suggests that children with ASD and/or ADHD may exhibit reduced engagement when reading texts they did not choose [37] or that is not related to their interests [22]. Thus, several clinical characteristics associated with ASD and ADHD may exert a powerful influence on reading engagement and comprehension. With the rising use of digital literacy platforms aimed at supporting children's reading skills, there is a critical need to accurately measure how children with ASD and/or ADHD engage with and comprehend the texts they read on these platforms.

3. PRESENT STUDY

3.1 Digital Literacy Platform

Amira [1] is an online, AI-powered reading platform that delivers real-time, adaptive literacy instruction. The virtual tutor,named Amira, listens to students as they read aloud, identifies reading miscues or skill gaps, and provides brief, real-time instructional supports (micro-interventions) aligned to the Science of Reading and tailored to the student's ability level and performance history. During comprehension dialogue activities, Amira prompts students with questions designed to assess and deepen skills that are aligned to grade-level Reading Comprehension standards. For students in grades 3 and above—where the cognitive and language demands are appropriate—Amira may initiate a comprehension dialogue micro-intervention rather than using the traditional multiple-choice format. These dialogues use open-ended prompts to probe the student's ability to demonstrate the skill, capturing explanation, reflection, or elaboration. Dialogues are modeled after authentic classroom questioning. The student responds either orally or by typing a response, and Amira uses advanced speech recognition and natural language processing (NLP) to capture and compare student responses against a detailed pre-defined rubric.

Each conversation can extend up to two turns of dialogue. The dialogue follows the structure of an opening prompt from the tutor, student response, a follow-up tutor prompt, student response, and final tutor response. A response timer is activated after the initial prompt is delivered, and students are given 10 seconds to begin their response to that turn. If no response is detected within this timeframe, the system will automatically deliver scaffolded support (a hint and a re-prompting of the same question). If any response attempt is detected, the student has 60 seconds in total to respond to the prompt on each turn. There is a visual timer present during the interaction to convey this per-turn time limit. The follow-up prompt is intended to scaffold the student towards further addressing rubric criteria that they did not adequately cover in their initial answer.

All response data—including ASR transcripts, timing, accuracy of the response based on the skills being taught, and behavioral markers such as hesitation or repetition—is logged for subsequent analysis, enabling researchers to investigate both dialogue engagement and comprehension skill performance within a dialogic reading context. For this study, we focus solely on the audio recordings and transcribed stu-

Table 2: Subset of acoustic features from eGeMAPS [23] use in analysis grouped by category.

Domain	Features
Temporal	Loudness Peaks Per Sec; Voiced segment length (s: mean, std. dev.); Unvoiced segment length (s: mean, std. dev.)
Energy	Harmonic-to-Noise ratio (mean, std. dev.)
Frequency	Fundamental Frequency (F0: mean, std. dev., 20th, 50th, 80th percentiles); F0 mean rising slope; F0 mean falling slope; jitter (mean, std. dev.)
Spectral	Alpha ratio, voiced (mean, std. dev.); Alpha ratio, unvoiced (mean); Hammarberg index, voiced (mean, std. dev.); Hammarberg index, unvoiced (mean, std. dev.); Spectral flux, voiced (mean, std. dev.); Spectral flux, unvoiced (mean); Spectral slope 0–500 Hz (mean, std. dev.); Spectral slope 500–1500 Hz (mean, std. dev.)

dent responses from the comprehension dialogues described above.

3.2 Methods

3.2.1 Participants and Data Collection

Participants who consented to be contacted for research studies were recruited via the Center for Autism Research (CAR) at the Children's Hospital of Philadelphia (CHOP). CHOP's Electronic Health Records (EHR) database. 1000 emails per week were sent out to CHOP patients based on certain selection criteria, including (a) diagnosis of autism spectrum and/or attention deficit/hyperactivity spectrum disorder or not, (b) age 5-12 years, and (c) in the "learning to read" phase according to parent report. 144 children aged 5-12 years with a diagnosis of autism (N=29), ADHD (N=55), autism + ADHD (N=38), or no diagnoses of autism or ADHD (N=22) consented to participate in a 7-week at-home reading intervention pilot study. Once enrolled, participants were instructed to read four to five stories per week on Amira , or for at least 30 minutes. Caregivers completed surveys providing basic demographic information and feedback on their child's experience with Amira. Full demographic details for participants can be seen in Table 1. This study was overseen by the Institutional Review Boards at CHOP and MDRC.

3.2.2 Acoustic Features and their Extraction

For each of the comprehension activity turns, we extract acoustic features based on the extended Geneva Minimalistic Acoustic Parameter set (eGeMAPS) [23] using the OpenSMILE toolkit[25]. eGeMAPS is considered a high quality acoustic feature set for use in emotion recognition tasks [19], which are closely related to the engagement identification question. eGeMAPS consists of 25 low-level acoustic features comprising four key categories related to these tasks: prosody, temporal, pitch, and spectral features. Acoustic features are extracted at regular intervals (e.g, every 10 ms) from speech samples and the resulting feature time series is mapped to fixed-dimensional feature vectors by applying one or more statistical functions (e.g., mean, standard deviation, percentiles), resulting in 88 features[1] for each student response turn. For frequency values, we focus solely on the fundamental frequency F_0 which has been used in prior studies as a measure of distinguishing pitch values between neurodivergent and neurotypical students [53]. This results in a subset of 49 acoustic features that we use for our analysis as seen in Table 2.

Table 3: Breakdown of the study dataset based on values with the parent-reported engagement labels: not engaged (NE), Somewhat Engaged (SE), and Very Engaged (VE). Only students with audio recording files are included in the count.

Clinical Group	Not Engaged	Somewhat Engaged	Very Engaged
ADHD	1	17	26
ASD	0	8	13
ASD+ADHD	1	12	8
Not ASD or ADHD	0	4	8

Prosodic features attempt to characterize the expressive qualities of speech including voice quality, rhythm, and intonation that convey emotion and emphasis; examples include jitter, shimmer, and harmonic noise ratio measures.

Frequency features attempt to characterize how high or low the voice sounds and how it varies over time, capturing both the fundamental frequency (F_0, perceived as pitch) and the resonant frequencies of the vocal tract (formants). As mentioned above, we only analyze fundamental frequency values in this work. These features were crucial in the work of Litman et al. [44] which showed that pitch was statistically significant for discriminating between engaged and disengaged students.

Temporal features attempt to characterize speech timing, including speaking rate and pause frequency. We consider the rate of speech, number of pauses based on loudness values, and variations in voiced and unvoiced segment lengths, which have been used in prior work discriminating between student engagement levels [44].

Spectral features are features that correspond to the spectral shape, such as slope, which are frequently used for affect recognition [23, 61]. These also include the first four Mel-Frequency Cepstral Coefficients (MFCCs), which have a documented association with valence and level of interest [24].

For further details regarding feature extraction (e.g., frame step, window size, MFCC filterbank/DCT parameters, functionals applied to each acoustic feature), consult [19] and [23].

3.2.3 Parent Reported Engagement (PRE) Labels

Following seven weeks of the at-home intervention, parents were given a survey to gather information about their child's

[1]Not all statistical functions are applied to all low-level acoustic features.

experience with the literacy learning system. This survey included a specific question about how engaged their child was while interacting with the tutor with three possible values: *Not Engaged*, *Somewhat Engaged*, and *Very Engaged*. This measure, which we will refer to as the parent-reported engagement (PRE) label, represents a relatively basic measure of engagement, as it does not ask parents to distinguish between the various ways in which engagement might manifest. However, it represents a valuable perspective on engagement from caregivers who are most familiar with the participants' unique focus styles and avoids concerns about the reliability of children's self-report data [21, 28].

PRE was provided by the parents of 139 participants, with 98 of those participants having audio recordings available for comprehension conversations. Labels were highly skewed towards the *Very Engaged* and *Somewhat Engaged* values with only 4 participants reported as *Not Engaged* during the sessions, only two of whom had audio recordings. As such, any patterns observed involving the Not Engaged group should be considered exploratory. The full distribution of clinical diagnosis based on engagement level can be seen in Table 3. We exclude any students who have fewer than two audio recordings present in the data. We apply the parent-reported engagement (PRE) level as a measure of overall engagement propensity to all comprehension activities with audio recording for the student. This is not intended to indicate turn-level engagement, but instead enable us to identify what acoustic features are correlated with children's general engagement statement.

3.2.4 Data Preprocessing

We conducted a series of preprocessing steps. In order to ensure that each participant had enough acoustic data for analysis, we first selected for students who had participated in at least two comprehension activities. We then aggregated all of the comprehension conversation turns for that student and aligned them with the appropriate audio file. Acoustic features were extracted using the OpenSMILE [25] toolkit for each of the student conversational turns. We collected system-generated transcriptions of student responses, which were processed through a simple word count function to generate verbal response counts for each turn. We then align the transcribed student response data, audio files, and the demographic and engagement reports from the parent surveys[2].

3.2.5 Measuring the Effect of Diagnosis x Engagement

To examine effects of clinical diagnosis and PRE levels on acoustic features while accounting for the fact that we have multiple audio recordings for each child, we employed population average models using generalized estimating equations (GEE). GEE models are well-suited for correlated data and provide robust inference without requiring explicit modeling of subject-specific random effects [43, 59, 75]. We also explored the use of mixed-effect models; however, they could not be applied across all the desired acoustic features due to limited within-child variability.

[2]The resulting dataset will be released for future work following the completion of the requisite anonymization process.

Table 4: Number of acoustic features showing significant population-level effects after FDR correction, stratified by feature category and predictor.

Feature Category	Diagnosis	Eng.	Diagnosis × Eng.
Energy	0	3	3
Frequency	0	6	8
Spectral	0	14	27
Temporal	0	2	5
Total	**0**	**25**	**33**

For each acoustic feature mentioned above, we fit a Gaussian GEE of the form:

$$\begin{aligned} Feature_{ij} = \beta_0 + \boldsymbol{\beta}_1^\top \text{Diagnosis}_i + \beta_2 \text{Engagement}_i \\ + \boldsymbol{\beta}_3^\top \left(\text{Diagnosis}_i \times \text{Engagement}_i\right) \\ + \beta_4 \text{Age}_i + \beta_4 \text{Sex}_i + \varepsilon_{ij}. \end{aligned} \quad (1)$$

where i represents children and j represents individual acoustic observations. Individual acoustic observations are represented by a vector of acoustic features from OpenSMILE that were extracted from a single turn in the comprehension dialogue. These models included clinical diagnosis, engagement, and the interaction of diagnosis and engagement as categorical predictors, with child age (mean-centered) and sex (parent-reported assigned sex at birth) as covariates. They were fit using the python *statsmodels* package [60] with the correlation structure set to exchangeable to account for the within-child correlation from the repeated observations [43]. Given the broad range of values for different acoustic features, we normalized the values using *StandardScaler* from *scikit-learn* [55]. We also use the *statsmodels* package to account for possible false-discovery rates (FDR) for diagnosis, engagement, and interaction effects with the Benjamini-Hochberg false discovery rate procedure [8] with adjusted p-values set using the methodology defined by Yekutieli and Benjamini [72].

4. RESULTS

We examine the results of fitting a GEE model across the 49 acoustic features in Table 2 as well as the verbal response count of the student responses. In Table 4, we present the acoustic features that are the most impacted by engagement, diagnosis or the combination of diagnosis and engagement. The parent-reported level of engagement acts as an independent predictor of acoustic features across all the categories. There were no statistically significant diagnosis-related effects present in the dataset. The interaction effects of diagnosis and parent-reported engagement are distributed across all of the feature categories.

4.1 Verbal Response Count

Table 5: GEE Results for Verbal Response Count. This table shows the FDR-adjusted p-values across all model terms. None of the values were considered statistically significant.

Predictor	FDR-adjusted p-value
Diagnosis	0.0627
Engagement	0.2420
Diagnosis × Engagement	0.2998
Age	0.1256
Sex	0.3986

In alignment with prior work in verbal engagement, we created a GEE model for the normalized verbal response count. This is taken as the count of words from the transcribed student response for a single turn. The results are displayed in Table 5. Our findings demonstrate that there was no statistically significant impact of engagement, diagnosis, or the interaction of the two on this metric. This suggests that this feature is not dependent on any of these categories.

4.2 Effect of Age and Sex on Results

We account for variations in age and sex in our results by adding them as intercepts to the GEE model. The results that we report for all engagement, diagnosis, and their interaction are those that did not have a statistically significant influence from these variables. Of the 49 acoustic features evaluated, only one had a statistically significant association age: the standard deviation of jitter. Mean child age had a positive coefficient of 0.101, indicating that as children get older than the mean age (in our case 8.4 years old), their variability in jitter levels increased as well. Child sex (as reported by parents in the demographic survey) did not have a statistically significant association with any of the acoustic features tested.

4.3 Engagement Effects

The GEE model shows that PRE levels have an effect on three *energy*-related features (i.e., shimmer, mean Harmonic-to-Noise Ratio and standard deviation of the Harmonic-to-Noise Ratio). PRE also impacts a number of *frequency* features (e.g., those related to the pitch based on F_0 semitone values and jitter, and changes in consecutive F_0 frames) and *spectral shape* features (e.g., Alpha Ratio, Hammarberg Index, and Spectral Slope values). In addition, PRE affects both the mean values of voiced segment length as well as loudness peaks per second - both of which are associated with speaking rates. These findings are consistent with prior work evaluating fluctuations in acoustic features related to arousal, engagement, and emotion [3, 7, 24, 44]. The majority of the contrast effects for the model appear between the *Not Engaged* and *Very Engaged* groups, however, we do see a meaningful difference between shimmer values for the *Somewhat Engaged* and *Very Engaged* groups. Students in the Somewhat Engaged groups (regardless of clinical diagnosis) exhibited higher mean values of shimmer than those in the Very Engaged group.

4.4 Diagnosis Effects

The GEE analysis of our data did not result in any statistically significant effects for diagnosis as an independent predictor. These findings are surprising given a large body of existing research that demonstrates noticeable differences in prosody, pitch, and voice quality for individuals with autism spectrum disorder vs. neurotypical peers [9, 48, 53, 54]. It is possible that no differences were detected in this study due to high variability in the speech characteristics of individuals with a given diagnosis or the fact that this sample was collected in a highly constrained (and non-social) context. There are still context-dependent diagnostic differences within the dataset that vary based on the child's parent-reported engagement level.

4.5 Diagnosis x Engagement Effects

As shown in Table 4, thirty-three acoustic features exhibited significant interactions between clinical diagnosis and PRE, indicating that diagnostic differences in vocal production depended on PRE. Multiple acoustic categories showed interaction effects, including three associated with *energy*, eight associated with *frequency*, twenty-seven involved with *spectral shape*, and five involved with *temporal values*. Of these features, 18 of them demonstrated an interaction effect without the presence of a statistically significant effect from one of the other predictors. We report the full set of the interaction effects in Table 6. Notably, features related to pitch distribution, spectral variability, and voice quality showed the strongest evidence of context-dependent diagnostic effects, underscoring the importance of considering engagement state when interpreting acoustic markers of clinical diagnosis in educational interactions. The contrast effects referencing Not Engaged in the term should be interpreted as exploratory since there were only 2 students in the analyzed data with audio recordings at this engagement propensity level. Coefficients and patterns reported for the Somewhat Engaged level are representative of a more substantial number of participants and observations in the dataset.

4.5.1 Energy

All three of the features in the energy category demonstrated interaction effects: the mean Harmonics-to-Noise (HNR) ratio and the standard deviation for the shimmer values. However, none of the individual contrast effects between groups registered as statistically significant. There are still some trends that are present in the dataset that should be mentioned for future exploration. Autistic children who were more engaged exhibited higher values of HNR whereas the neurotypical group had the opposite pattern. As seen in Figure 3, For HNR, the ADHD and ASD + ADHD groups more closely resemble the pattern exhibited by neurotypical children, with both showing lower values when Very Engaged vs. Somewhat Engaged. When children in the ADHD and ASD+ADHD groups are rated as Not Engaged, the HNR values are dramatically lower than for the mid-level of engagement, but there is high variability in these groups. This finding is harder to interpret given that there are a very limited number of samples in the dataset with the Not Engaged label. From a practical perspective, when HNR is higher it is indicative of clearer phonation [3] — which means that children with ASD are pronouncing words more clearly when more engaged whilst the other groups are actually reducing their clarity.

We also see opposing patterns between the neurotypical and ASD groups for the shimmer feature. The standard deviation for shimmer is lower for more engaged neurotypical children, whereas it is higher for more engaged ASD children. The more-engaged ADHD group shows a slight increase in shimmer values. Higher shimmer values mean that there is more intensity variability, which is frequently associated with high arousal emotions and higher levels of stress [3].

4.5.2 Frequency

Variations in the frequency characteristics of speech are highly indicative of individual's arousal levels and engagement [3, 23, 44]. In Figure 4, we can see the difference in mean values

Table 6: Acoustic features that exhibit a statistically significant contrast effect (after FDR) based on the interaction of diagnosis × engagement. The reference group for the clinical diagnosis is always *Not ASD or ADHD* and for engagement it is always *Very Engaged*, not engaged is represented as NE and somewhat engaged is represented as SE. Cells show GEE coefficient (Standard Error). * indicates $p < .05$. Dashes indicate non-significant contrasts. † indicates contrast excluded due to anomalous SE = 0. All values rounded to 4 decimals.

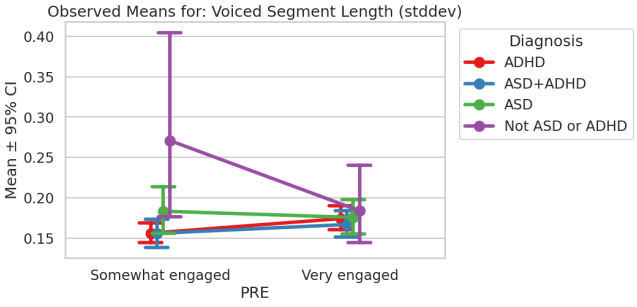

Figure 1: Observed means of the variations of standard deviation in voice segment length across different clinical diagnoses and parent reported levels of engagement.

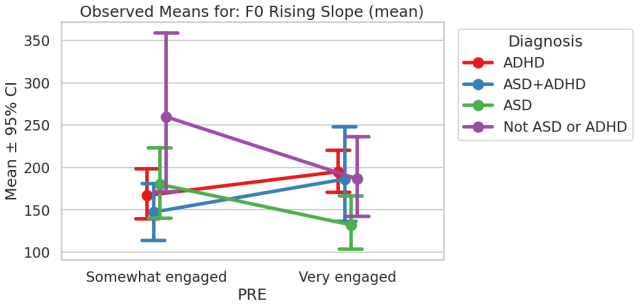

Figure 2: Diagnosis-group level means of the of F0 rising slope across different clinical diagnoses and parent reported levels of engagement.

for the rising slope for F_0 across different clinical diagnoses and engagement values. The neurotypical group exhibits a higher range of values than all of the neurodivergent groups when rated as Somewhat Engaged. These values increase between the Somewhat and Very Engaged groups for individuals with ADHD or ASD+ADHD, but they decrease for neurotypical participants. Essentially, this is indicating that when individuals with ADHD are more engaged they raise their pitch more quickly, whereas the neurotypical students will drop the rate of pitch change when more engaged.

We also notice a stark contrast between the trends of mean values for jitter between the participants with ASD when compared to all other children. Jitter values are higher for Very Engaged ASD children than the Somewhat Engaged group. The pattern is flipped for neurotypical, ADHD, and ASD+ADHD children. Jitter indicates pitch fluctuations in speech and higher values are typically associated with more tremulous or nervous speech [45]. This variation could indicate that individuals with ASD tremble more when they are highly engaged with content than their peers.

For both of these values, the only contrast effect that was statistically significant was for the Not Engaged group with ADHD when compared to the Very Engaged-Neurotypical group. However, given the extremely small sample size of

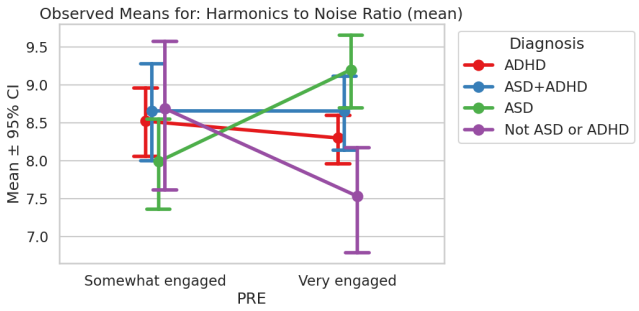

Figure 3: Diagnosis-group level means of the Harmonics-to-noise ratio across different clinical diagnoses and parent reported levels of engagement.

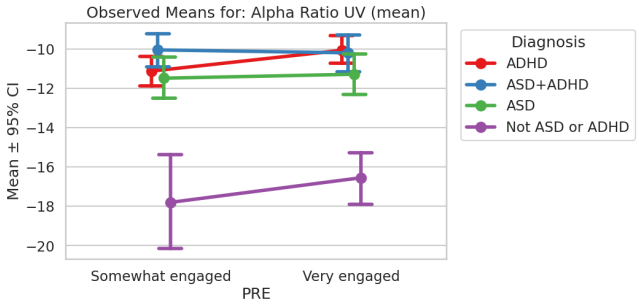

Figure 4: Diagnostic-group level means of the mean Alpha Ratio UV for each of the clinical diagnoses and parent reported levels of engagement.

the Not Engaged group, this result should be verified with a larger dataset.

4.5.3 *Spectral*

Interaction effects are most prevalent for the spectral or vocal shape related features. There are statistically significant effects for the unvoiced Alpha Ratio, voiced and unvoiced Hammarberg Index, MFCC values, spectral Flux and spectral slope values. As seen in Table 9, there are not any statistically significant contrast effects for any of the clinical diagnosis in the Very Engaged group. This means that across the clinical diagnosis, when children were Very Engaged, the spectral shape-related acoustic features appear in a uniform manner in the dataset. On the other hand, there are meaningful contrasts between different clinical diagnosis and the Not Engaged and Somewhat Engaged groups.

In our limited set of Not Engaged participants, we see a number of contrasting acoustic features from the Not ASD or ADHD:Very Engaged reference group. As demonstrated in Figure 4, the ASD+ADHD group had higher values for unvoiced Alpha Ratios than the reference, whereas the ASD group had substantially lower ones. A low Alpha ratio is usually associated with a softer voice. The coefficients for the unoviced Hammarberg Index mirror these results; high Hammarberg indices are associated with a softer voice, whereas lower values would be indicative of a sharper one [62]. This could be indicative of a trend where individuals with ADHD speak in a much softer tone when disengaged, as opposed to disengaged individuals with ASD+ADHD who are talking in sharper tones. Generally speaking, the mean values for the Alpha Ratio of the Not ASD or ADHD groups are considerably lower than they are for all other groups in the study.

We do see significant contrast effects in the Somewhat Engaged groups for some of the MFCC values. This includes lower values for MFCC1V for ADHD children and higher values for MFCC4 for Autistic Students. MFCC1V values are usually associated with variations in spectral tilt, with higher values indicating larger amounts of variation. Instead, for the ADHD children this is saying that there is a limited amount of variation in the spectral tilt when they are Somewhat Engaged.

4.5.4 *Temporal*

All of the temporal features had a statistically significant interaction effect, but only three of them had one without the presence of an Engagement effect. This includes the standard deviation of the voiced segment length as well as the mean and standard deviations of the unvoiced segment length. Lower standard deviations of voiced segment length mean that the speaker is talking with a more regular cadence, usually associated with a confident manner of speaking, whereas higher values can be indicative of hesitant speech [29]. In figure 1, we can see that the neurotypical group shows a much larger decrease in this value between the Very Engaged and Somewhat Engaged participants when compared to the neurodivergent groups. This suggests that neurotypical children will sound more confident when they have higher engagement levels, but this perceived confidence shift may not be reflected in the speech of their neurodivergent peers.

5. DISCUSSION

5.1 Implications for Automatic Detection of Reading Engagement

In highlighting the effects of parent-reported engagement, diagnosis, and their interaction on acoustic features, our ultimate goal is to better inform future models of reading engagement for diverse learner groups. Our results highlight the fact that acoustic features may be a more equitable signal than verbal response count for measuring reading engagement in the home setting. We recommend the use of acoustic features that demonstrate robust effects related to engagement propensity while taking into account interactions between clinical diagnosis and engagement levels. This includes Hammarberg index values, Alpha ratios, shimmer, as well as loudness peaks per second and mean values of voiced segment length. However, all of these values were associated with a statistically significant interaction effect between the diagnosis and PRE. Special consideration should be given when using acoustic features to predict engagement levels for children with ASD. In our data, we notice high variability for a number of acoustic features within this group. This may make it especially difficult to accurately predict engagement levels since there may not be a consistent observable speech pattern.

These findings are intended to be used to create adaptive at-home literacy learning systems. The differences presented in acoustic measures for individuals with ASD or ADHD

are not indicative of a reading comprehension deficit. Nor should they be used as a diagnostic tool. Instead, these should be interpreted as evidence that we need to develop more complex acoustic-feature based predictive models that can account for variations in the presentation of speech-related engagement signals. With effective real-time engagement predictions, it is possible to implement interventions that keep students engaged with reading materials at home, and in turns lead to more opportunities for improving their reading comprehension skills.

5.2 Limitations and Future Directions

The detectors presented here are comparable in performance to a range of others in previous research, but would still benefit from further refinement, particularly from efforts that could expand our data collection efforts. It is important to note that this a sensitivity study on the collected audio data, and we are not evaluating the impact of a particular reading intervention on features related to reading engagement. This is a logical next step in future research studies - leveraging these features as a non-invasive measure of the effect of particular reading interventions on student reading engagement in different subgroups.

Like many studies, this analysis would have benefited from the use of a larger data set. This is particularly challenging because the majority of available speech datasets that might serve as points of comparison–especially those used to identify acoustic features related to engagement–are composed of adult speech samples from extemporaneous speech. In addition to raw frequency differences between adult and child acoustic data, children often exhibit different speech behaviors in extemporaneous speech, and our samples were further constrained by the activities students were asked to perform as part of a task related to learning to reading.

In addition to benefiting generally from a larger sample, we would also benefit from diversifying our sample. Importantly, our current dataset is representative of children with several possible clinical conditions, which allowed us to present findings related to neurodiversity that have been understudied in the EDM community. However, it would still benefit from a more robust sampling of ethnic, socioeconomic, and English language learner status as variation within those diagnoses, as those factors are known to affect students' language patterns.

Future work should also look for ways to improve the granularity of the engagement labels, as the PRE labels were derived from parental evaluations of students' experience with the learning system in its entirety. However, even the most engaged child will not be completely engaged during every lesson, or every turn of that lesson. Ideally, in future experiments we will complement this measure with finer-grained labels, allowing us to develop a more nuanced understanding how students who are highly engaged overall might vary over the course of several weeks while also developing a more nuanced understanding of the acoustic indicators of this engagement. Additionally, we acknowledge that our dataset contained a very small number of students in the not engaged group. Ideally, in a larger sample we would have a less imbalanced set of engagement levels. Such efforts would also substantially improve our predictive modeling of real-time engagement.

Finally, we aim to expand our approach to comprehension conversation data. During a single comprehension activity, the microphone is open for a fixed period of time where the student responds to - at most - two conversational turns. This substantially limits the amount of data that can be collected, as students may be cut off before they are able to fully participate with the task. There may be strategic reasons for the learning system to continue such practices, but it would be good to consider ways in which we might better understand how this constraint affects student engagement, particularly as we seek to use more fine-grained levels than those employed in this study.

Still, the course-grained PRE labels deployed here–in addition to serving as an important step towards better understanding home usage–might also help us to better understand when apparent disengagement at the micro-level may be incidental. For example, they likely indicate a students' overall propensity to re-engage with the learning system, which could be used to help filter more fine-grained, moment-to-moment patterns in order to better understand which students need greater support.

6. CONCLUSION

In this paper, we have explored the use of acoustic features to measure reading engagement during online learning sessions across a diverse learner population. Acoustic features provide a non-invasive manner of capturing critical data related to student behavior and affect while they are working with a digital literacy platform at home. We present the nuances of modeling reading engagement for children with ADHD, ASD, or both based on the unique characteristics of these conditions. Our study includes audio and transcription data collected from 144 children over the course of several weeks who engaged in passage reading and reading comprehension tasks while at home.

Specifically, we use parental reports of engagement (PRE) with the system and clinical diagnosis to create generalized estimating equations (GEEs) for engagement-related acoustic features. We compare the effect of clinical diagnosis, parent report of engagement, child age and sex on a set of 49 acoustic features across 98 students from our dataset. We confirmed the results of prior work demonstrating that certain acoustic features related to frequency, temporal, spectral, and energy characteristics of speech are consistently influenced by engagement levels [44]. However, we discovered that all of the features are also impacted by the interaction between clinical diagnosis and engagement level. This suggests a critical need to develop more robust measures for measuring reading engagement that can account for the unique characteristics associated with different neurodevelopmental conditions. In future work, we hope to collect more refined turn-level engagement annotations that can be used to develop acoustic feature-driven models of reading engagement based on these findings. Furthermore, by integrating these measures of reading engagement into digital literacy systems we can create personalized adaptive learning interventions to increase individual students' reading comprehension gains.

7. ACKNOWLEDGMENTS

The research reported here was supported by the Institute of Education Sciences, U.S. Department of Education, through Grant R305C240040. The opinions expressed are those of the authors and do not represent views of the Institute or the U.S. Department of Education. This work was made possible by our collaborators at Digital Promise, the Amira Learning team, the Children's Hospital of Philadelphia, and MDRC. The authors would also like to express our gratitude to the families who participated in our study and contributed to this line of research.

APPENDIX

A. PER-FEATURE GEE RESULTS

Table 7 includes all acoustic features organized by high level category as well as the results of fitting the GEE model for that feature.

Exploring Disagreement as a Dialogue Policy

Mariah Bradford
Colorado State University
mbrad@rams.colostate.edu

ABSTRACT

With growing interest in applying artificially intelligent agents to collaborative learning settings, we are challenged to identify meaningful moments for these agents to intervene. I propose moments of disagreement within groups to be pivotal - that is, the interaction can lead to learning gains or disruption depending on how they are handled. With that in mind, I plan to run user studies over a short group task to explore a baseline turn-based intervention policy compared to a disagreement-driven intervention policy. While these moments are nuanced, this study will provide some initial insights into a specific, educationally grounded, and explainable intervention policy during a group task conflict.

Keywords

User study, Disagreement, Collaboration, Dialogue policy

1. INTRODUCTION TO THE PROBLEM

Collaborative learning is a well-studied area in education, with growing opportunity to apply artificially intelligent agents as helpers [1, 6, 7, 19]. However, as we develop the necessary architectures to handle multimodal, multiparty, and in-person interactions, we are still left with a gap between the technology and educationally grounded human-AI interaction [6]. One question we must ground in the learning sciences is when to intervene, if at all. A closely related question is how conflict is handled in small groups. In a previous article, Rummel et al. contrasted two possible extremes for the future of AI in collaborative work: a dystopian future and a utopian future [17]. Notably, the two paths both included group conflict and dialogue policies. The dystopian scenerio described a pair with frequent conflict, frustrating interventions, and unexplainable outcomes from the AI. In the utopian scenerio, however, the dialogue policy was explainable, and conflict was treated as a nuanced situation, with helpful interventions aimed at productive conversation [17]. While both futures are still far off, I aim to explore the intersection of dialogue policy and conflict management in small group tasks. Previous work has explored human-centered dialogue policies for collaborative learning [4, 6], including wizard-of-oz analysis to inform dialogue policy and real-time, state-based dialogue policies. For example, in [6], group states were automatically classified and used to determine interventions. One outcome of this study was showcasing that active negotiations could contribute to unproductive perseverence; that is, when students were addressing task conflict, they could get stuck. While this was one consideration in their dialogue policy, I am interested in isolating this aspect and diving deeper into its impact on collaborative outcomes.

2. PROPOSED FRAMING AND SOLUTION

Collaborative work often requires progress toward common ground [19, 26]. However, if task conflict arises, it can create an obstacle which requires negotiation to resolve [7, 8]. While previous work has shown mixed outcomes, with task conflict sometimes being a positive learning event [8] and sometimes a negative learning event [9, 11], the literature seems to indicate that the difference in these pivotal moments is how the conflict is handled [9, 12, 20, 23]. With this in mind, I propose that disagreement can serve as a signal to intervene. In particular, disagreements which are not being resolved or are escalating may require assistance from an external party [3, 6, 7]. Disagreement, for this paper, refers to a conflict in which we cannot reach common ground with the current task propositions [26]. For example, if one student believes the answer is A, and another student believes the answer is *not* A, they must resolve this disagreement if common ground is needed for the task. To explore this specific dialogue policy, I will implement user studies with a real-time, multimodal common ground tracking system [21] with the addition of interventions.

DPIP Task. For this project, groups of four will complete a *Distributed Partial Information Puzzle* (DPIP) [25], wherein participants work together to recreate a target Lego structure. Following the jigsaw approach used in [6], three of the participants have unique information and must work together to piece their knowledge into one combined solution (in my case, the Lego structure). The remaining participant acts as the builder, constructing the structure but without any information to start with. This task requires collaboration between each team member, as well as negotiating unique perspectives to reach the final outcome. In this task, disagreement naturally arises as participants attempt to orient together and give directions to the builder. An exam-

ple of this can be seen in Fig 2. The group thought they were correctly completing the task, but they came to an impass when there was a conflict between two members' views. While one participant (P4) saw a red block in a specific location, another participant (P2) believed it should have been an orange block. The builder places a red, removes it, and places an orange, at which point P4 rests her head in her hands as a sign of confusion. At this point, the solution is that the participants are actually referring to two separate corners; each person is correct, but their beliefs about their wall orientation needs to be adjusted. I propose moments such as this one to be potentially helpful moments for an agent to intervene.

Dialogue

P4 And there's two of [red].
P2 I have orange on top of the red.
P4 Orange?
P4 Oh no.
P4 That's not right for me.

Figure 1: Participants reach a disagreement while working on the DPIP task. Participants are labeled P1, P2, P3, and P4, from left to right. P4 sees a red square while P2 sees an orange square, and the group must re-negotiate their task beliefs before they can continue.

Intervention Agents. The interventions will be provided as speech and on-screen text to the group. Interventions will come from one of three fine-tuned versions of Meta-Llama-3-8B-Instruct: Identity Preference Optimization (IPO) [2], Proximal Policy Optimization (PPO) [18], or the Frictional Agent Alignment Framework (FAAF) [15]. IPO and PPO are well-known fine-tuning techniques; IPO is an offline contrastive approach, while PPO is an online reinforcement learning approach. FAAF is a more recent approach which fine-tunes the model to act as a collaborator in a frictive state, which makes it more aligned with the goal of the intervention.

Dialogue Policy Conditions. I will compare two dialogue policies. My baseline condition is to provide an intervention every seven utterances. This was based on a qualitative exploration between five and ten utterances, with five being too frequent and ten being too far apart. This baseline provides an explainable but naive comparison, with no meaningful or education-based policy; it is simply rule-based. The second condition provides an intervention when a disagreement is detected in the dialogue by a large language model. This condition explores the specific challenge of conflict management in collaborative learning. It is also grounded in existing literature on collaborative learning, which has found conflict to be impactful - either positively or negatively - on the group [8].

Evaluation. I will evaluate the outcomes based on three dimensions; group speed, correctness of final structure, and user experience. The group speed will simply consider the time taken to complete the task. Correctness of the structure will compare the group's final structure with the target structure. User experience will include a self-report survey [13, 14] after completing the task as well as behavioral signals for user engagement with the agent. Signals will include verbal and nonverbal items such as visual attention toward the agent and speaking over the agent [5].

LLM Disagreement Detection. Besides the user outcomes, I also must evaluate the performance of the system on the detection task. The task will be detecting disagreement in small group dialogues. One additional challenge in this task is that disagreements are often expressed *implicitly* through contradiction rather than directly stating disagreement [24]. Because of this, I aim to leverage the interpretive power in LLMs. To evaluate LLMs on this task, I will test multiple models on various datasets. I will explore the model's performance on the Delidata dataset [10]. This is a dataset of small groups performing the Wason card selection task, a well-known reasoning task [22], and includes labels for explicit group disagreement. I will also label a subset of this dataset for implicit disagreement in order to compare performance on both types of expression. Further, I will use a synthetic version of the DPIP task presented in [16]. These provide some initial evaluation on the LLM performance of detecting disagreement, which will serve as the gate for my proposed dialogue policy exploration.

3. EXPECTED CONTRIBUTIONS

This research will offer insight into the impact of intervening during disagreement as a dialogue policy. This builds off of prior work exploring group state dialogue policy, which considers unproductive negotiations as a group state [6], but isolates this one aspect for further investigation. This also provides a study outline for other specific rule-based and educationally-grounded dialogue policy explorations. As we move toward AI assistants in collaborative learning, it is critical to have explainable and grounded dialogue policy. Disagreement is an especially interesting moment because of its potential to negatively or positively impact the group; this makes it worth investigating further on its own. It is also a timely challenge, as we now have live multimodal and multiparty systems. It's important to bridge the gap between the existence of the system and years of foundational learning sciences outlining the challenges which arise in collaborative settings. I propose a human-centered AI approach, which focuses on one proposed moment of intervention known to be pivotal in collaboration and tests it in a user study with a live agent system.

Identifying When Support Matters Most: Longitudinal LMS Behaviors To Predict Failure Trajectories

Christopher Steadman
University of Minnesota
Minneapolis, MN, USA
stead032@umn.edu

ABSTRACT

Student retention remains a significant challenge in higher education, with early academic failure frequently serving as an initial indicator of attrition. Yet many models focus on binary outcomes that can mask the severity of academic struggle for some students. Thus, this ongoing research focuses on students who experienced multiple failures (i.e., receiving two or more D or F grades) in their first semester. We are exploring two research questions: 1) how early can we meaningfully identify students at risk of experiencing multiple failures, and 2) what behavioral indicators might signal that a student is more likely to experience multiple failures. Using longitudinal LMS data from the Unizin Data Platform for 5,094 first-year students at a large public university, we applied machine learning to 352 temporal features to identify at-risk students. Preliminary models achieved a peak recall of 0.68, identifying critical intervention windows at Week 5 and Week 11. These findings suggest that while early behavioral markers exist, mid-semester disengagement may represent a critical point for "just-in-time" intervention.

Keywords

Student retention, Academic failure, Temporal modeling

1. INTRODUCTION

The transition to college can be a challenging time for students, both on a personal and institutional level [25, 10]. These challenges can act as barriers to student success, with student retention remaining a persistent challenge for higher education institutions. It represents a critical goal for all stakeholders due to both the economic and social benefits for individuals [12] and the financial and academic stability it signals for institutions [21, 20]. Despite years of effort, retention rates have remained relatively stagnant [8], with recent data indicating that approximately 35% of US students fail to graduate from their program [6]. First-year students are particularly vulnerable to attrition with roughly 18% of students failing to return for their second year [19].

Christopher Steadman. Identifying When Support Matters Most: Longitudinal LMS Behaviors To Predict Failure Trajectories. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) Proceedings of the 19th International Conference on Educational Data Mining, Seoul, Republic of Korea, June, 2026, pp. 855–859. International Educational Data Mining Society (2026).

Importantly, students' experiences of transition and persistence, as well as their choices about remaining in higher education, are shaped by differences in prior preparation, available support networks, and broader structural inequities [25, 3]. Understanding when and how these transition and persistence challenges emerge has therefore become as important as measuring whether students ultimately persist. Institutions are increasingly seeking ways to identify actionable moments during the semester when timely support can alter a student's trajectory, rather than relying solely on retrospective indicators, such as final grades or withdrawal status. To address these needs, institutions have turned to Learning Analytics and 'Big Data' to identify behavioral patterns that place students at risk. Early efforts in this space proved that data from Learning Management Systems (LMS), such as login frequency and resource engagement, could serve as a viable 'early warning system' [15]. More recent work has used machine learning techniques to assess how administrative, demographic, and behavioral data can be used to accurately identify and predict students' level of success or failure [4, 5]. Furthermore, there is a growing shift toward progressive modeling that leverages the temporal nature of student behavior to identify academic struggle as it unfolds, rather than after the fact [27, 17].

However, a gap remains in understanding how academic difficulty can accumulate to place students on a path toward attrition. Prior work has considered failure and attrition as binary constructs, distinguishing only between students who succeed and those who do not. While analytically convenient, this framing can obscure meaningful variation in how academic struggle unfolds, particularly for students who encounter repeated setbacks within a single term. Experiencing multiple course failures may represent a qualitatively different moment in a student's trajectory [16], one that signals compounding academic and motivational challenges rather than an isolated difficulty. This study investigates this indicator at scale, considering the relationship between students' LMS usage across courses and their risk of experiencing 'multiple failures', here defined as receiving two or more D or F grades in their first semester.

2. RELATED WORK

Early work using LMS behavioral trace data demonstrated their importance in predicting academic risk. For example, volume metrics, such as frequency and duration of logins, were found to be significant predictors of performance, accounting for as much as 31% of the variability in final grades

[18]. Subsequent work using richer datasets demonstrated that combining interaction logs with grade data and other non-LMS enrollment data could reliably be used for early outcome prediction (in some cases as soon as the 8th day of instruction) [23] and successfully used for automated intervention [1]. As data availability has increased, this work has expanded beyond descriptive analytics to include machine learning approaches that integrate demographic, administrative, and behavioral data sources in an effort to improve predictive accuracy [2, 14, 13]. These more complex datasets have allowed us to better model academic risk as a dynamic process rather than a static outcome. However, analyzing LMS behavior at an institutional level has historically been hindered by fragmented data systems that often lacked uniformity both within and between institutions. In response to this, the Unizin Consortium was developed as a collaborative effort among research universities to create a shared, standardized data infrastructure to support the analysis of student engagement at-scale [28].

Despite the substantial progress that has been made in identifying students at risk of dropout or course failure, most studies operationalize academic risk using binary outcome measures or focus on failures that occur within individual courses or programs. Such approaches provide useful indicators of eventual outcomes but may obscure differences in how academic difficulties emerge and accumulate across a student's broader educational experience. Specifically, experiencing multiple course failures in a single academic term represents one such profile. For first-year students in particular, this pattern can trigger institutional probationary policies, financial aid consequences, and reduced opportunities for academic recovery, creating a precarious academic position early in their college careers [26, 22, 7]. Despite the institutional significance, relatively little research has examined how behavioral signals associated with multiple concurrent failures develop over time.

The present study thus extends prior learning analytics work by shifting the analytic focus from predicting whether failure occurs to understanding when and how clusters of academic difficulty become detectable. Recent increases in the availability of large-scale, institutionally integrated educational data have made it possible to examine these patterns with greater temporal and contextual resolution than was previously feasible. Leveraging longitudinal LMS engagement data drawn from the Unizin Data Platform, which links behavioral and administrative records within an authentic undergraduate environment, we (1) model multiple-course failure as a distinct outcome, and (2) examine the temporal emergence of behavioral indicators that may support earlier, more targeted intervention. Guided by this perspective, we consider two research questions:

RQ1: How well can we predict that students will experience multiple failures in their first semester of college?

RQ2: How early can we make meaningful predictions about students' failure rate?

By using behavioral data related to students' LMS engagement, we aim to identify the factors that most meaningfully predict student failure with the long-term goal of providing more timely and equitable institutional intervention.

3. METHODOLOGY

Data for this study were collected from the Unizin Data Platform, which is a repository of LMS records from the 16 university members of Unizin [28]. We initially queried the database to select all students who were first enrolled in their program in Fall 2022 at a large public Midwestern university. The initial sample comprised 8,382 students. To ensure the analysis focused on a consistent first-year undergraduate cohort, a multi-step data cleaning process was applied. First, we excluded students with interaction records prior to the start of the semester to remove continuing or transfer students. Second, students with fewer than 3 graded courses were excluded as a proxy for full-time status. Additionally, we removed students enrolled in graduate-level coursework. The final analytic sample consisted of 5,094 students. Due to student privacy concerns, the original dataset used in this study is not publicly available. However, a synthetic dataset that mirrors the original data structure and the complete analysis pipeline are available on the Open Science Framework [24].

For this analysis, we defined 'failure' as a grade below a C-, based on institutional guidelines. Using this definition, we categorized students into three groups based on their Fall 2022 performance: (1) Multiple Failure (N=160), comprising students with two or more Ds or Fs; (2) Single Failure (N=321), serving as a comparative failure group for students with exactly one D or F; and (3) Non-Failure (N=4613), representing students who met all course requirements. Descriptive results indicate that students who experience multiple instances of failure in their first semester exhibit significantly lower term-to-term persistence, with only 50% continuing past their first year, compared to 92% for non-failure students. This highlights the need to understand what behaviors may be most associated with these failure experiences, so that we can better intervene before these students leave.

3.1 Feature Engineering

Features were extracted from the Unizin Data Platform to capture granular behavioral patterns. The study period covered a 16 week semester, resulting in a total of 240 base features (15 per week).

3.1.1 Base Feature Identification

We identified core behavioral metrics to serve as proxies for student engagement and self-regulation.

1. **Temporal Interaction Patterns**: To assess possible temporal interaction effects, we categorized all LMS events into four distinct time-of-day bins (12:00 AM – 6:00 AM, 6:00 AM – 12:00 PM, 12:00 PM – 6:00 PM, and 6:00 PM – 12:00 AM).

2. **Self-Regulation Proxies**: Engagement with the LMS "To-Do" list and calendar features was used to represent planning and organizational behavior. This aligns with prior research that shows that learners with higher self-regulation skills engage in greater planning behaviors than their peers [11].

3. **Volume and Intensity**: We captured the duration of active sessions, the frequency of specific actions, and the number of distinct 30-minute study sessions.

4. **Performance Indicators**: Unizin compares assignment submission timestamps to due dates to calculate submission latency, and these calculations were used to create an average weekly submission metric.

3.1.2 Feature Engineering and Aggregation

To simulate real-time predictive capabilities, raw event data were aggregated at the weekly level. To account for different dimensions of student effort, we engineered three specific types of derived features:

1. **Time-Binned Counts & Proportions**: For each time-of-day bin, we calculated both the raw count of interactions and the proportion of the week's total activity that occurred within that bin.

2. **Proportional Engagement**: We calculated the proportion of total weekly To-Do list activity relative to overall To-Do list engagement to normalize planning behavior.

3. **Cumulative Features**: To capture longitudinal trends, we created cumulative versions of count and duration metrics. For interaction counts, the four time-binned features were first summed to create a single "Total Interactions" metric for the week, which was then iteratively added to create a single "Cumulative Total Interactions" feature. All other non-proportional metrics (e.g., Student Activity Scores, Sessions) were aggregated individually. This process resulted in an additional 112 cumulative features, yielding a final dataset of 352 potential features.

To ensure the ecological validity of our predictive models, we implemented temporal constraints on the feature sets. At any given point in the semester (Week k), the model was restricted to a "snapshot" of the student's history up to that point. The total number of features available to the model at Week k is calculated as follows:

$$\text{Total Features} = (15 \times k) + (7 \times k) \quad (1)$$

In this calculation, 15 represents the base features generated each week (e.g., interaction counts, time-binned proportions), and 7 represents the longitudinal cumulative features (e.g., running totals of interactions). This approach ensures that the model never "sees" into the future and instead relies only on information that would be available to an instructor or institution in a real-time environment.

To prepare the dataset for modeling, we performed feature selection and normalization independently for each weekly model iteration. Specifically, we removed features that were strongly correlated (r>.90) to address potential multicollinearity, scaled features using a standardized scaler, and applied the Synthetic Minority Over-sampling Technique (SMOTE) [9] to the training folds to address class imbalances.

3.2 Modeling Approach

The dataset was split at the student level into 80% training data (N = 4075) and 20% testing data (N = 1019). We created 5 different randomized training and testing splits and applied a 5-fold cross-validation procedure using a Randomized Search (k=5) to each of the training datasets to tune model parameters and obtain reliable performance estimates. We utilized Random Forest and XGBoost classifiers due to their ability to handle non-linear relationships and high-dimensional data. Given that the Multiple Failure group represents a relatively small proportion of the population (3.1%), we addressed the severe class imbalance by optimizing our models for Recall (sensitivity). Recall reflects the proportion of truly "at-risk" students that the model successfully identifies. In this context, low recall would mean students experiencing multiple failures are overlooked by the system, preventing institutions from offering potential support during critical periods. Because prior research has shown that early academic setbacks can compound and contribute to attrition, missing these students (false negatives) represents the most consequential form of error.

4. CURRENT PROGRESS

Model performance indicates that meaningful detection becomes possible relatively early in the term. By Week 5, recall for the Multiple Failure group exceeded 50%, suggesting that behavioral differences associated with later academic difficulty are already observable within the first month of coursework. Performance continued to improve as more temporal data became available, reaching a peak recall of .68 by Week 15 (Figure 1).

To interpret which behaviors contributed most strongly to model predictions, we examined the SHAPley Additive Explanations (SHAP) values (Figure 2). This analysis revealed two critical windows for intervention. First, features related to late submissions in the first month remained among the strongest predictors of multiple failure even at the end of the semester. This indicates that a pattern of procrastination established in the first few weeks of college is a persistent indicator of risk. Second, interaction behavior during Weeks 8-11 emerged as highly influential. This period immediately follows midterm exams, and suggests that this drop in interaction may reflect academic disengagement following disappointing midterm results. This window may thus be an important window for increased support, especially for students already showing signs of academic difficulty.

Our analysis also revealed that not all instances of academic difficulty reflect the same underlying process. While students in the Multiple Failure group exhibit more generalized patterns of disengagement that became increasingly detectable over time, Single Failure students were frequently misclassified as Non-Failure. This suggests that failing a single course may be an idiosyncratic, localized, or course-specific challenge tied to the demands of a particular course rather than a broad behavioral shift.

5. CONTRIBUTION AND FUTURE WORK

This research offers both theoretical and practical contributions to the Educational Data Mining and Learning Sciences communities. From a learning science perspective, this work offers theoretical insights into how academic disengagement

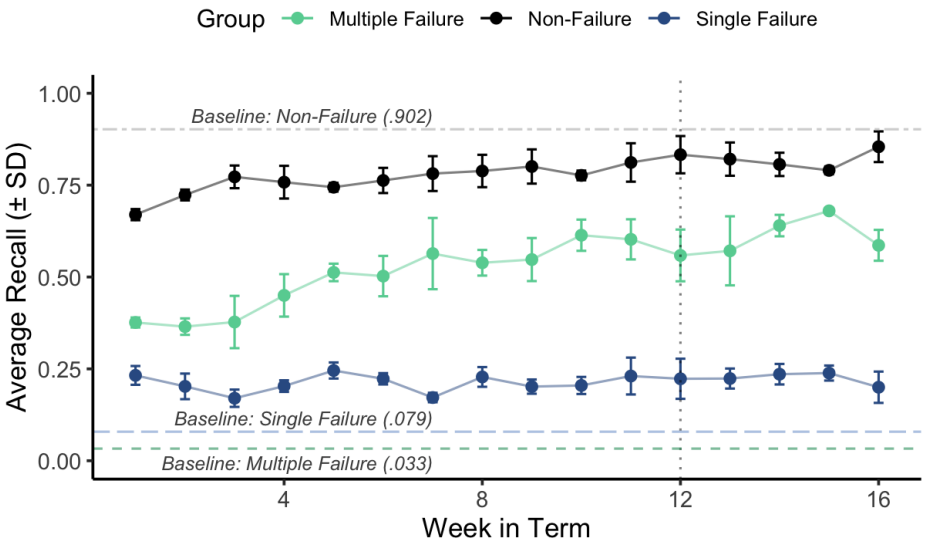

Figure 1: Weekly model recall performance by student failure outcome. Solid lines represent the average recall achieved by the model for each group, while horizontal dashed lines represent the baseline recall for each specific group, established using a stratified dummy classifier. The vertical dotted line at Week 12 marks the Thanksgiving break, corresponding to a period of atypical LMS engagement.

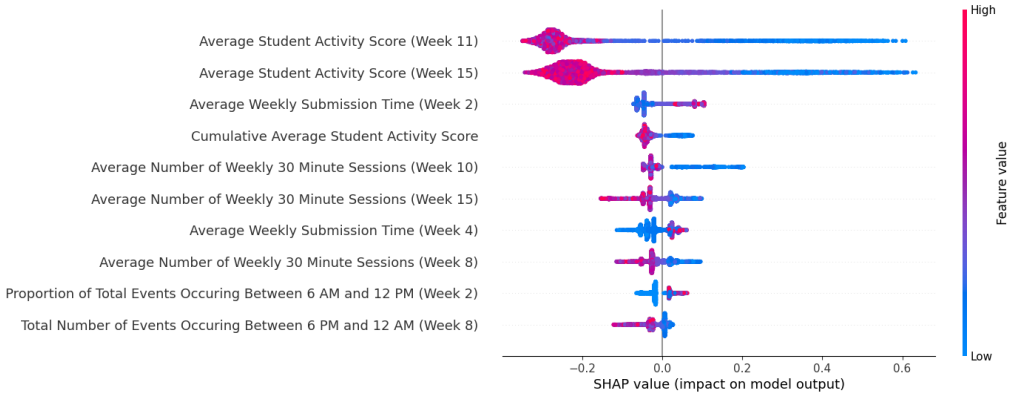

Figure 2: SHAP summary plot for the top 10 features for the Multiple Failure group

unfolds at an institutional level. Additionally, the use of the Unizin Data Platform ensures that the methodology applied to this work is scalable and provides a blueprint for standardized institution-level learning analytics. This type of cross-institutional work will be key for determining whether observed behavioral patterns can generalize to other settings.

With an eye towards generalizability, future research will look to replicate these findings across different first-year cohorts to solidify the timing of key behavioral windows. We would also like to explore additional analyses using explainable AI and deep learning methods to improve model performance and ensure that we are accurately identifying the behavioral patterns that are most predictive of repeated failure. In addition, we will be carrying out a longitudinal analysis to assess how behavioral signatures evolve over time, particularly for students in the Multiple Failure group. Assessing how behaviors change over time for students who persisted despite experiencing significant early academic setbacks could provide insights into the types of behaviors that allowed them to persist. Lastly, we plan to integrate disciplinary data to determine if certain majors or gateway courses exhibit unique engagement signatures and explore how course difficulty influences learning behavior.

The ultimate goal of this research is to support the development of proactive early warning systems. Identifying 'Multiple Failure' trajectories allows institutions to deploy limited advising resources to the struggling students most likely to drop out. By focusing on 'just-in-time' intervention, we can better identify the students who are struggling the most as they transition to college and provide them with the support they need before academic probation or permanent withdrawal occurs.

Identifying and Modeling Epistemic Emotions in Collaborative Problem-Solving

Sifatul Anindho

nathaniel.blanchard@colostate.edu

ABSTRACT

Epistemic emotions such as confusion and curiosity play a central role in learning. However, they are difficult to identify in collaborative problem-solving. Existing approaches usually rely on behavioral coding or self-reports, both of which results in contradictory empirical results in different populations and environments, raising concerns about generalization, construct validity and what constitutes the gold-standard ground truth. Here, I propose and outline my ongoing investigation of measurement and analysis of epistemic emotions in collaborative problem solving. I adopt a retrospective cued-recall framework to capture self-reported cognitive-affective states, providing a minimally disruptive and ecologically valid method of annotating internal experience. I then characterize the temporal and relational structure of these states using ordered network analysis, demonstrating how epistemic emotions exhibit cooccurrence and transition dynamics in collaborative problem-solving. Finally, I propose to systematically compare multiple representations of affect to examine how annotation methods, temporal alignment, and representational choices influence what is measured, observed, and interpreted as epistemic emotional dynamics.

Keywords

Epistemic Emotions, Collaborative Problem-Solving, Affective Computing, Ordered Network Analysis, Multimodal Modeling

1. INTRODUCTION

Epistemic emotions, such as confusion and boredom, can play a central role in learning, influencing how learner's interpret information and construct knowledge [1], and this influence can sometimes be quite complex. Baker et al. [2] showed that some of these emotions can have completely different effects on learning depending on their incidence and persistence. Confusion, for example, is an epistemic emotion often associated with impasse or difficulty. Researchers find that confusion can actually be beneficial for learning when appropriately resolved, leading to deeper understanding. But when it persists without resolution, it's shown to be detrimental in the same population groups [3]. This highlights that the impact of epistemic emotions depends not only on their presence, but also on their temporal dynamics. Therefore, developing computational models that can automatically detect and track these states in real-world learning environments is of growing interest in the EDM commmunity. Such models have the potential to power intelligent tutoring systems that provide pedagogical interventions which support productive phases of such emotions and break disruptive cycles.

Epistemic emotions often manifest differently across learning environments. Prior work has shown that both the incidence and temporal dynamics of affective states vary across learning contexts and interaction conditions, with the same emotion exhibiting different patterns and consequences depending on the task and environment [2, 3]. A relatively less explored learning environment is collaborative-problem solving (CPS). CPS is a learning paradigm when two or more individuals come together to solve problems with a shared goal [4]. In such settings, identification of epistemic emotions becomes challenging, since learning emerges through interaction, coordination, and shared reasoning among multiple individuals. In CPS, emotions are shaped by social dynamics, including negotiation, disagreement, and joint attention. As a result, these states are often subtle, context dependent, and regulated in ways that differ from individual learning scenarios. This introduces additional challenges for measurement. There is no clear gold-standard ground truth for cognitive-affective states in CPS, and internal experiences must be inferred through self-reports or external observations, both of which are inherently imperfect. In particular, social masking and regulation—where individuals suppress, exaggerate, or modulate their expressions in response to group dynamics—can lead to misalignment between observable signals and true internal states [5]. Conversely, the temporal imprecision and recall bias in self-reports complicates the alignment between subjective labels and multimodal behavioral data [6].

Here, I briefly discuss my ongoing work and outline a research roadmap for investigating how epistemic emotions in collaborative problem-solving can be more reliably measured. The central premise is that cognitive-affective states must be conceptualized as temporally dynamic, context dependent, and methodologically constructed phenomena. To

this end, this work is organized into three components. First, I employ retrospective cued recall to capture self-reported cognitive-affective states, providing a non-intrusive and minimally disruptive measure of internal experience. Second, I analyze the temporal and relational structure of these states using ordered network analysis, revealing patterns of co-occurrence and transition that challenge static labeling assumptions. Third, I examine how different temporal resolutions and aggregation strategies influence the interpretation of these states, drawing on recent work on affective chronometry and dynamics. Together, these components aim to characterize what different forms of "ground truth" capture, and how methodological choices shape our understanding of cognitive-affective processes in collaborative learning.

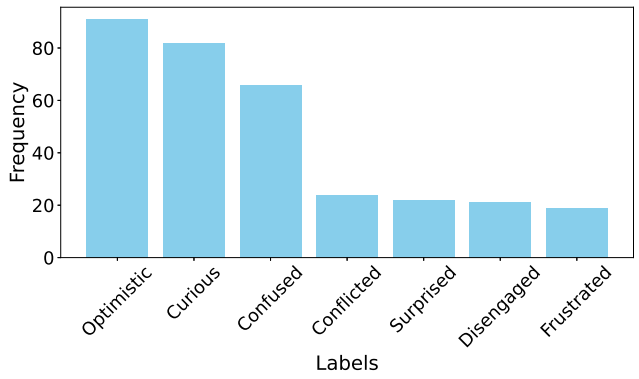
2. THE PROBLEM AND STATE OF THE ART

Research in educational psychology has long argued that emotions are not peripheral to learning, but are tightly coupled with attention, motivation, self-regulation, and knowledge construction. Control-value theory, for example, frames achievement emotions as arising from learners' appraisals of control and value [7]. In parallel, research on epistemic emotions has emphasized that states such as confusion are especially relevant during complex sense-making because they arise from cognitive disequilibrium, uncertainty, and the effort to resolve gaps in understanding [8, 3]. Researchers have also shown that affect in learning could be modeled as dynamic, contextual, and tied to the learner's meaning-making process rather than as a static display of basic emotion [1].

Within EDM, this perspective motivated a substantial body of work on detecting learner affect from observations, interaction traces, and multimodal signals. A particularly influential line of research focused on building reliable observational infrastructures for studying affect in authentic educational settings. The Baker Rodrigo Ocumpaugh Monitoring Protocol (BROMP) was developed to support minimally disruptive field observation of student affect and behavior, and became one of the field's most widely used protocols for collecting affect labels in classrooms and digital learning environments [9]. This foregrounded a measurement problem that is easy to underestimate in machine learning: affect detectors are only as meaningful as the labels and populations on which they are built. Ocumpaugh et al. [10] demonstrated that affect detectors trained in one population or setting may not generalize well to another, even when the nominal task appears similar. Zambrano et al. [11] compared different ground-truth measures of emotion and showed that the choice of measurement approach can materially shape the conclusions drawn from affective modeling studies.

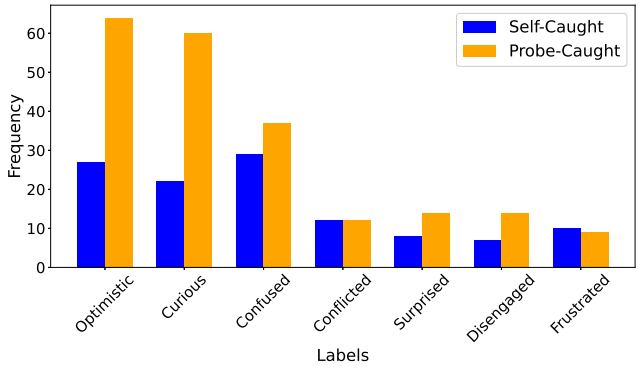
Previous research also suggests that states such as confusion, frustration, and surprise are meaningful in how they unfold and interact over time [12]. For instance, confusion may support learning when it transitions into productive inquiry, yet hinder progress when it persists or co-occurs with disengagement. However, empirical approaches that aggregate affective experiences across entire activities or treat them as independent labels have struggled to recover consistent evidence for these theoretical dynamics [13, 14]. This disconnect points to a key limitation in current modeling approaches: by collapsing temporal sequences into static representations, they discard the relational and transitional structure that defines epistemic emotions.

These concerns become sharper in collaborative problem-solving. Compared to individual tutoring or solo problem-solving, collaborative settings introduce social regulation and coordination. Learners may mask confusion to preserve competence in front of peers, suppress frustration to maintain group harmony, or display attentiveness strategically while being disengaged internally [5]. This creates a particularly difficult setting for automatic affect detection because the mapping from observable signal to felt state is neither direct nor stable [15, 7]. For this reason, collaborative learning is not simply another application domain for affect models developed elsewhere. It is a setting that stresses the assumptions built into those models.



Taken together, this literature points to three key design requirements for the present work. First, measurement must be treated as a primary research problem rather than a preprocessing step, echoing prior work on observational rigor, population validity, and the instability of ground truth in affect modeling [**?**, 10, 11]. Second, epistemic emotions should be conceptualized as dynamic and relational processes rather than independent, static categories, consistent with work on affective dynamics, confusion resolution, and state transitions [3]. Third, collaborative problem-solving should be treated as a distinct affective context, where social regulation, masking, and interactional dependencies complicate the mapping between observable signals and internal states. Building on these insights, I investigate the problem of ground truth for epistemic emotions by combining construct-aligned annotation, analysis of temporal and relational structure, and systematic examination of how different measurements of affect shape our understanding of cognitive-affective processes in collaborative learning.

3. THEORETICAL FRAMING



The theoretical framing of my doctoral research is grounded in the premise that epistemic emotions in collaborative problem solving are mutually inclusive and context-dependent processes, rather than static and independently observable states. Drawing from educational psychology, epistemic emotions arise from learners' interactions with uncertainty, task demands, and social context, and their role in learning depends on how they evolve over time and in relation to other states. From this perspective, the notion of a single, fixed ground truth for affect is inherently problematic. Instead, what is commonly treated as "ground truth" should be viewed as a methodological construct shaped by choices in measurement, temporal aggregation, and representation. To adress this, I ground the investigation in a sequence of studies that progressively examine how epistemic emotions can be measured and represented in collaborative problem-solving in a meaningful and valid way. Some of this work has already been carried, and the remaining is in plan.

3.1 Foundations (Completed Work)

Initially, I explored the space of internal states that arise in collaborative contexts. Using a retrospective cued-recall paradigm, I collected data of collaborative problem-solving sessions where participants were asked to verbalize their internal states while reviewing recordings of their group in-

(a) Overall frequency distribution of reported affective states

(b) Distribution across reporting mechanisms

Figure 1: Distribution of reported cognitive-affective states in our dataset

teractions. These internal monologues were transcribed and thematically analyzed, revealing a set of prevalent epistemic states—including labels such as *conflicted* and *reserved*—that are not commonly emphasized in prior work on individual learning. Analysis of n-grams and manually extracted keywords further supported the consistency of these states, and semantic similarity analysis confirmed coherence within and across identified categories. This study established both the diversity and context-specificity of epistemic emotions in collaborative settings [16].

Building on this, I developed a structured self-report framework in which participants labeled their cognitive-affective states using a more structured retrospective protocol that provided a subset of the initial labels, either spontaneously (self-caught) or in response to periodic probes (probe-caught). This enabled the collection of a more formalized dataset of retrospectively reported affective states that are temporally anchored across multiple groups. along with rich metadata including timestamps, reporting type, and participant roles. Analysis of the resulting data showed that frequency distributions of reported states were largely consistent across reporting mechanisms, with subtle but meaningful differences (Figure 1). For example, states such as *confused* were reported more frequently in self-caught conditions, while probe-caught reports tended to capture lower-arousal states, suggesting that participants may use available labels as approximations for a broader "neutral-engaged" condition. These findings highlight how measurement choices influence not only what is captured, but how affective states are interpreted. I further examined the temporal characteristics of these states by analyzing their distribution over normalized task time. Figure 2 shows a scatterplot of affective state reports over normalized collaborative task time. This analysis revealed systematic patterns: disengagement increased over time, likely reflecting fatigue or waning attention, while confusion persisted over longer durations, consistent with its characterization as a sustained epistemic state [3]. Frustration exhibited mid-task peaks, aligning with its role as an intermediate response to prolonged difficulty [1], and surprise appeared as a transient, intermittent state [2]. These results reinforce that epistemic emotions are not static events, but temporally structured processes with distinct dynamics [17].

Next, I investigated the relational structure of these epistemic emotions using ordered network analysis (ONA) (see Figure 3) [18]. This work showed that epistemic emotions form a structured system of co-occurrences and transitions that cannot be recovered from frequency-based summaries alone. In particular, I identified a stable "epistemic core" linking curiosity, optimism, and confusion, while also observing that reporting mechanisms (self-caught vs. probe-caught) and group performance (faster vs. slower groups) emphasize different aspects of this structure. For example, the roles of confusion and disengagement shift in their relationship to conflict depending on group dynamics, suggesting that the meaning of a state is contingent on its position within an interactional sequence [19].

3.2 Proposed Analysis (Future Work)

The next stage of this doctoral research centers on a systematic investigation of ground truth by comparing different annotation methods, temporal resolutions, and data modalities. Specifically, I propose a set of studies organized around three questions. First, how do different annotation methods capture epistemic emotions? I will compare self-reported states obtained through retrospective cued recall with externally observable indicators derived from multimodal behavioral data, including facial action units, vocal prosody, and conversational features. Agreement will be assessed using both categorical metrics (e.g., Cohen's κ, F1) and distributional comparisons, while also examining where and why divergence occurs. Rather than treating disagreement as error, I will analyze systematic patterns of misalignment, such as cases where internal reports indicate confusion but observable signals remain neutral, as potential evidence of social masking or regulation.

Second, how does temporal alignment influence interpretations of affect? I will investigate the temporal fidelity of different signals by comparing self-reported events with behavioral data across varying temporal windows (e.g., $\pm$1s, $\pm$5s, $\pm$10s) and aggregation strategies. This includes evaluating whether certain modalities exhibit leading or lagging relationships with reported states, and whether affective episodes are better represented as point events or temporally diffuse intervals. Building on prior work in affective chronometry, I will quantify differences in persistence, onset, and decay across representations, examining how these properties shift under different temporal assumptions.

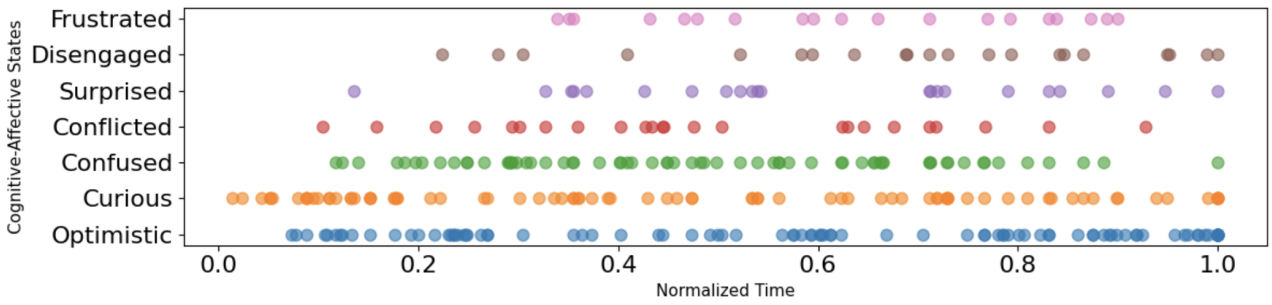


Figure 2: Distribution of affective state reports over normalized collaborative session time

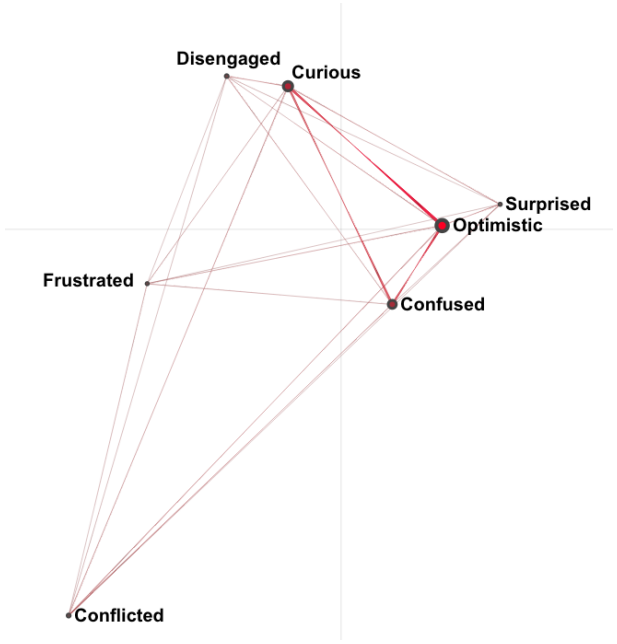

Figure 3: ONA network for affective states across all CPS groups. The first two dimensions explain 34.3% and 21.3% of the variance

Third, how do representational choices shape conclusions about affective dynamics? Using ordered network analysis and related sequence-based methods, I will construct relational representations of affect from each operationalization (e.g., raw self-reports, temporally aggregated labels, multimodal-derived signals) and compare their structural properties. This includes examining differences in cooccurrence patterns, transition probabilities, and higher-order structures such as stable "cores" or hubs of interaction. By comparing these structures across representations, I aim to identify which aspects of affective dynamics are robust to measurement choices and which are artifacts of specific annotation or aggregation strategies.

Across these studies, the goal is not to identify a single "correct" ground truth, but to characterize the space of plausible representations and the conditions under which they converge or diverge. In doing so, this work treats ground truth as a multi-faceted construct that must be interrogated empirically. The outcome is a framework for understanding how methodological decisions—ranging from annotation protocols to temporal segmentation—shape both the analysis and interpretation of cognitive-affective states in collaborative learning.

4. CONTRIBUTION AND IMPACT

This research aims to contribute to both the learning sciences and computer science communities by reframing the problem of affect modeling as a question of measurement, representation, and validity.

From a learning sciences perspective, this work advances the study of epistemic emotions in collaborative settings by emphasizing construct validity and temporal dynamics. By leveraging retrospective cued recall, it provides a minimally disruptive yet theoretically grounded approach to capturing internal states in naturalistic environments. Further, by analyzing the temporal and relational structure of these states, this work contributes to a deeper understanding of how epistemic emotions unfold during collaborative problem-solving, moving beyond frequency-based accounts toward process-oriented representations. More broadly, it contributes to ongoing discussions in EDM regarding the nature of ground truth, the role of measurement in learning analytics, and the interpretation of affective data.

From a computer science perspective, this work frames affect modeling as a data-centric machine learning problem, where the primary challenge lies in the definition and reliability of supervision signals rather than model capacity alone. By systematically examining how different annotation strategies, temporal resolutions, and representations influence downstream analysis, this research provides insights into learning under weak, subjective, and temporally misaligned supervision. These challenges are not unique to affect modeling, but arise in many real-world machine learning settings involving human-centered data. As such, this work contributes to broader efforts in machine learning to understand label uncertainty, temporal misalignment, and the relationship between data collection methods and model behavior.

Finally, this research has implications for the design of affect-aware systems in education. By clarifying what different forms of "ground truth" capture and where they fall short, this work provides a foundation for developing models and systems that are more interpretable, robust, and aligned with the constructs they aim to represent. In doing so, it can

support the development of educational technologies that respond not only to observable behavior, but to the underlying cognitive-affective processes that drive learning.

Modeling Epistemic Vigilance in Collaborative Problem Solving: A Multimodal Approach Using Social Deduction as a Proxy Testbed

Videep Venkatesha

Nathaniel Blanchard
Colorado State University

ABSTRACT

AI agents that support collaborative learning must detect reasoning failures as they unfold: misconceptions propagating unchecked, weak claims accepted without scrutiny, and participants reasoning actively but reaching wrong conclusions. Building such detection models requires datasets where these failures occur and are labeled and yet existing collaborative datasets capture only idealized cooperation under shared epistemic goals. This paper presents a doctoral research program addressing this gap through three integrated contributions: (1) a multi-layer annotation framework that traces communicative acts through belief updates to epistemic vigilance assessments, operationalizing constructs from cognitive science for behavioral annotation; (2) a proxy testbed using social deduction games where unreliable information enters group reasoning with known provenance, enabling traceable study of how epistemic failures propagate; and (3) multi-person egocentric sensing that captures participant-relative signals unavailable to traditional exocentric setups. This work extends my prior research on propositional extraction, common ground tracking, deliberation chain modeling, and automated annotation in collaborative settings, building toward an integrated system that can monitor the quality of group reasoning in real time. Pilot data from a 6-player session demonstrates that failed vigilance, belief fragmentation, and traceable misinformation effects emerge naturally and are captured by the framework.

Keywords

epistemic vigilance, collaborative problem solving, multimodal learning analytics, Theory of Mind, belief dynamics

1. PROBLEM AND STATE OF THE ART

Collaborative problem solving (CPS) is a core competency in education that involves sharing information, building common ground, reasoning about evidence, forming and revising beliefs, and coordinating action through communication [15, 18]. For collaboration to be productive, participants must evaluate each other's contributions, weigh evidence, update beliefs, and coordinate decisions often under genuine uncertainty, especially when there is no single clear answer and the task is open-ended. The quality of this evaluation process, what Sperber et al. [16] term epistemic vigilance, is what separates productive collaboration from groups that converge on misconceptions or fragment into incompatible understandings.

The challenge for educational data mining is that existing collaborative datasets overwhelmingly capture idealized cooperation. Corpora such as the DELI dataset [8] and frameworks like the General Competency Model [18] operationalize CPS under shared epistemic goals, where all participants work toward a correct answer. Real classrooms are messier where students unknowingly spread misconceptions, assert incorrect solutions with unwarranted confidence, freeload, or dominate discussions unproductively [3]. These dynamics of unreliable contributions, the natural heterogeneity of contributor quality, are pervasive in educational settings [9, 14] yet rare and unlabeled in controlled datasets. Without data where epistemic failures occur with known ground truth, building detection models is intractable.

A second gap concerns sensing modality. Current multimodal learning analytics for collaboration rely predominantly on exocentric sensing with overhead cameras and external microphones [1]. Egocentric sensing offers the potential to capture participant-relative signals that exocentric setups cannot reliably recover: whether a listener is attending to the speaker during a critical claim, or scanning others' reactions before updating a belief. Whether these first-person signals carry additional information about the social-cognitive constructs relevant to CPS, and epistemic vigilance in particular, is an open empirical question that this work aims to investigate.

1.1 Prior Work: Building Toward Epistemic Monitoring

My doctoral research has progressively built the computational infrastructure needed to model collaborative reasoning. This trajectory establishes both the technical foundations and the motivating gaps that the current work addresses.

Extracting what groups discuss. I developed methods for extracting task-relevant propositions from natural speech in collaborative settings, using cross-encoder architectures

adapted from coreference resolution [22]. This work established that the semantic content of group dialogue can be recovered automatically, even from noisy overlapping speech, and was later extended to handle automated transcription with minimal degradation [21]. These methods became a core component of TRACE, a real-time multimodal common ground tracking system that integrates speech, gesture, gaze, and object detection to model the shared beliefs of collaborating groups as they emerge [19].

Modeling how discussions evolve. I contributed to work on linking deliberation chains in collaborative dialogues, modeling the causal structure from earlier utterances to probing questions that drive group reasoning forward [13]. This work formalized the sequential structure of collaborative discourse, showing that probing interventions and their causal antecedents can be automatically clustered using joint learning frameworks.

Understanding the limits of automation. Most recently, I evaluated 13 LLMs across six model families on the task of annotating pedagogical moves in educational dialogue [20]. A key finding was that models achieve moderate agreement on content-focused categories with clear surface markers but fail on categories defined by pedagogical function, precisely the categories (like CPS facets) that require understanding speaker intent and social dynamics rather than surface text patterns.

The gap this work addresses. Collectively, this prior work can track *what* groups discuss and *whether* they reach agreement, but it cannot assess *whether the reasoning that led there was sound*. A group may converge on a shared belief through careful evidence evaluation or through uncritical acceptance of a confident but wrong claim. Current systems, including those I have helped built, treat convergence as success without evaluating the epistemic quality of the path. The present work addresses this gap directly, introducing a framework and testbed for studying how groups evaluate (or fail to evaluate) the reliability of contributions.

2. THEORETICAL FRAMING AND METHODOLOGY

2.1 Theoretical Foundations

The research integrates three theoretical frameworks. *Epistemic vigilance* [16] provides the overarching lens: the cognitive mechanism for evaluating incoming information by assessing source reliability and content plausibility rather than accepting claims uncritically. In collaborative learning, failed epistemic vigilance manifests as misconceptions spreading through groups, weak arguments being accepted without challenge, and overconfident errors going undetected.

Bayesian Theory of Mind [2] provides the belief-modeling framework, formalizing how observers infer others' mental states from observed behavior. In my framework, players report first-order beliefs (what they believe about others' roles) and second-order beliefs (what they think others believe about them), grounding Theory of Mind measurement in self-report data that can serve as supervision signals for computational models.

Argumentative Theory of Reasoning [12] motivates the focus on persuasion dynamics. Mercier and Sperber argue that reasoning quality in collaborative settings depends critically on the group's argumentative practices: whether claims are challenged, whether evidence is demanded, and whether the group evaluates contributions on epistemic merit rather than social dynamics.

2.2 Testbed: Social Deduction as a CPS Environment

I use the social deduction game Secret Hitler as a proxy testbed where players are secretly assigned cooperative or adversarial roles and engage in structured rounds of discussion, voting, and policy enactment. For the majority of players, the game is collaborative problem solving: pooling incomplete evidence, evaluating reliability of claims, and coordinating decisions under genuine uncertainty [15, 18]. A minority of players are structurally incentivized to introduce unreliable information such as asserting false claims with confidence, and undermining group reasoning. These contributions are functionally equivalent to the misconceptions and overconfident errors in collaboration. The epistemic challenge is shared, even though the underlying intent differs. Crucially, every piece of unreliable information has known provenance (role assignments provide ground truth), and the game enforces the information asymmetry that the hidden profile literature identifies as the hardest aspect of real collaboration [11, 17].

2.3 Multi-Layer Annotation Framework

The framework is hierarchical, with each layer targeting a progressively deeper dimension of group social-cognitive dynamics.

Layer 1: Communicative Acts. Each utterance is classified using the six-category persuasion strategy taxonomy from Lai et al. [10]: Identity Declaration, Accusation, Interrogation, Call for Action, Defense, and Evidence (Krippendorff's $\alpha > 0.6$). This layer draws on my prior work in propositional extraction [22] and epistemic move classification [19], extending those methods to a setting where communicative acts include deliberate misinformation. Categories like Interrogation and Defense parallel the questioning and justification behaviors that characterize productive student reasoning, the moments where a collaborator challenges a claim or defends their position with evidence, rather than accepting contributions uncritically.

Layer 2: Player-Reported Belief States. After each round, players report first-order beliefs about every other player's role (yielding calibration data against ground truth) and second-order beliefs about what others believe about them (enabling direct measurement of Theory of Mind accuracy [2]). These reports serve as supervision signals for models that must eventually infer beliefs from observable behavior alone. In the classroom parallel, this captures whether a collaborator can identify when someone else is not contributing productively to the group, whether through providing misleading information, dominating the discussion, or steering the group in an unproductive direction.

Layer 3: Epistemic Vigilance. Inferred post-hoc using Lay-

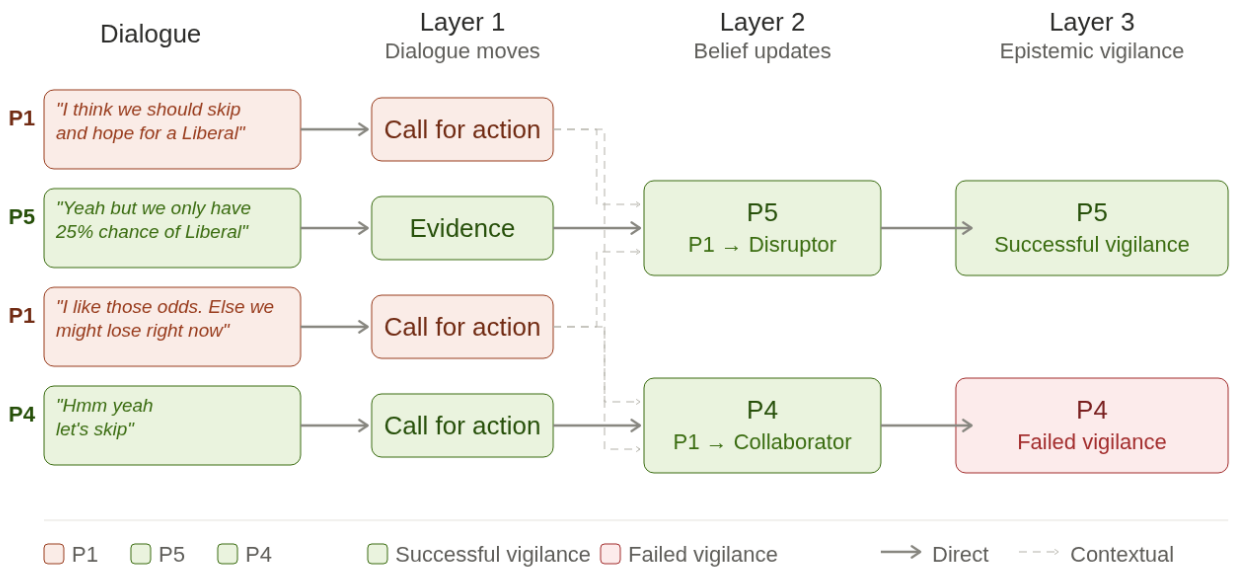

Figure 1: Three-layer annotation of a discussion phase. Utterances are classified by communicative function (Layer 1), linked to belief updates (Layer 2), and assessed against ground truth as successful or failed epistemic vigilance (Layer 3). Color indicates true role (red = adversarial, green = collaborative; hidden during play).

ers 1 and 2 together with ground-truth role assignments [16]. For each communicative act, we assess whether the receiver's belief update was warranted: *successful vigilance* (belief moved toward truth) or *failed vigilance* (belief moved away from truth). The cascading structure of communicative act → belief update → vigilance assessment aims to mirrors what a classroom agent must track, extending the common ground tracking paradigm from my prior work [19]. This layer captures not just whether students can identify unreliable contributions, but whether they actually succeeded in doing so, and by examining which communicative behaviors (Layer 1) precede successful vs. failed vigilance, we can study what kinds of group dynamics lead collaboration to succeed or break down.

Figure 1 illustrates this cascading structure with an excerpt from a pilot session. P1 (true role: Disruptive) advocates for an irrational move of skipping a turn and hoping for a favorable outcome. P5 correctly objects by presenting evidence that the odds are poor, updating their belief that P1 is a Disruptor showing successful vigilance. P4, however, accepts P1's reasoning and agrees to skip, maintaining the belief that P1 is a trustworthy Collaborator despite the weak justification: failed vigilance. The same exchange thus produces both outcomes in different receivers, and the framework captures exactly where and why the group's reasoning diverged.

2.4 Sensing Infrastructure

All players wear Meta Aria Gen 1 research glasses [5], capturing egocentric RGB video, eye-tracking data, and IMU signals. An overhead camera provides a synchronized exocentric reference view, producing $n + 1$ synchronized video streams per session wehre n is the numebr of players. This multi-person egocentric configuration enables gaze-derived features aligned with our annotation layers: gaze target identity at utterance onset, scanpath structure [4] during successful vs. failed vigilance episodes, and group-level attention divergence computed across all players which is a measure unavailable in single-viewpoint datasets [7, 6].

2.5 Research Trajectory

My research proceeds in three phases. *Phase 1 (current): Framework design and pilot validation.* I have designed the annotation framework and conducted pilot sessions to verify that target phenomena emerge naturally. *Phase 2: Data collection and annotation.* I will conduct additional sessions to build a dataset sufficient for computational modeling, adapting the annotation methods from my propositional extraction and deliberation chain work [22, 13] to this new setting. My evaluation of LLM annotation capabilities [20] will inform which layers can be partially automated and which require human coding. *Phase 3: Computational modeling.* Using the annotated multimodal data, I will train models that predict Layer 3 vigilance outcomes from observable behavioral features, systematically comparing egocentric-only, exocentric-only, and fused feature sets, building on the multimodal fusion architecture of TRACE [19].

3. PROGRESS TO DATE

Pilot data from two 6-player, 9-round session demonstrates that the target phenomena emerge naturally. Figure 2(a) tracks four collaborative players' evolving beliefs about P5, whose true role was Hitler/Disruptive. Despite 9 rounds

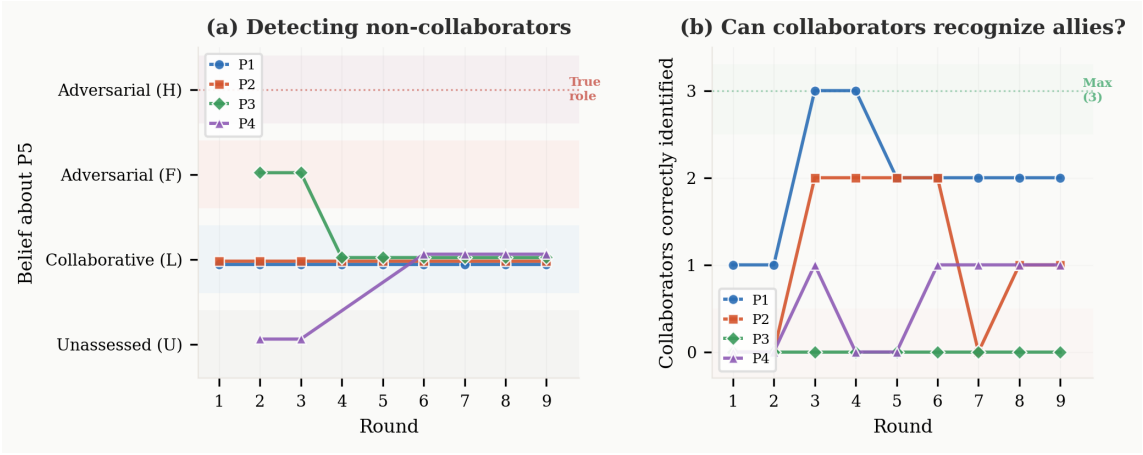

Figure 2: (a) Four collaborative players' beliefs about P5 (true role: Disruptive) across rounds. No collaborator ever correctly classified P5, illustrating failed vigilance. (b) Number of fellow collaborators each player correctly identified per round (max = 3).

of discussion and evidence, no collaborator ever correctly identified P5. P3 initially suspected P5 (Rounds 2–3) but reversed toward a collaborative classification by Round 4, constituting failed vigilance: P3 possessed a partially correct signal but abandoned it, likely in response to P5's communicative acts. Figure 2(b) reveals a complementary pattern where P3 correctly identified zero allies across all 9 rounds, placing every collaborator in the adversarial category which is the profile of a group member who is actively reasoning but systematically misdirected, analogous to a student who is engaged but whose contributions fragment rather than strengthen shared understanding [3]. Distinguishing active-but-counterproductive participation from constructive collaboration is precisely the capability the Layer 3 assessment operationalizes. P1, by contrast, peaked at identifying all three allies (Rounds 3–4) before declining, suggesting group-level belief fragmentation as unreliable information accumulated.

4. EXPECTED CONTRIBUTIONS AND IMPACT

For learning sciences. The annotation framework provides a structured methodology for studying how unreliable information propagates through collaborative groupsa phenomenon widely documented [3, 9] but rarely studied with the temporal granularity and ground truth this testbed provides. The operationalization of epistemic vigilance as a measurable construct in group behavioral data offers a new lens for understanding when and why collaborative reasoning fails.

For computer science. The testbed and dataset enable development of multimodal models for detecting reasoning failures in group settings. The multi-person egocentric sensing configuration provides a template for capturing participant-relative signals in small-group research, and the systematic comparison of egocentric vs. exocentric features will inform sensing design for future learning analytics systems.

For the broader EDM/AIED community. This work addresses a fundamental bottleneck: the scarcity of labeled data capturing collaborative dynamics beyond idealized cooperation. By providing a proxy testbed where epistemic failures occur frequently, with known ground truth, and with rich multimodal capture, the research accelerates model development that would be impractical to iterate on in instructional settings [18]. Combined with my prior work on propositional extraction, common ground tracking, and automated annotation evaluation, this research will produce an integrated pipeline: from sensing raw multimodal signals, through extracting propositional content, to assessing the epistemic quality of group reasoning—the full trajectory a collaboration monitoring agent would need to traverse.

Modeling Learner-AI Interaction in Time-Constrained Programming Tasks

Omkar Joshi
Centre for Educational Technology, Indian Institute of Technology Bombay, Mumbai, India
omkar.joshi21@gmail.com

ABSTRACT

The increasing use of AI coding assistants in programming environments is transforming how learners approach problem solving, particularly under time-constrained conditions. While prior research has examined perceptions and performance outcomes, there is limited understanding of how learners interact with AI tools at a behavioral level. This doctoral research adopts a data-driven approach to model learner-AI interaction in programming tasks, grounded in the theoretical framework of Self-Regulated Learning (SRL). The study collects fine-grained interaction logs from undergraduate and early-graduate computer science students completing algorithmic programming tasks with an AI coding assistant under both timed and untimed conditions. By capturing sequences of learner actions and AI queries, the research aims to (1) characterize AI usage patterns using process mining and sequential analysis, (2) model how time pressure alters behavioral transitions between coding, debugging, and AI-assisted activities, (3) identify distinct learner profiles through clustering of interaction features, and (4) develop and validate behavioral proxies for cognitive engagement and help-seeking using convergent analysis with self-report measures and qualitative examination of interaction sessions. Preliminary studies indicate a shift toward outcome-oriented behaviors and varied reliance on AI under time pressure, motivating the need for systematic modeling of interaction processes. The expected contributions include new representations of learner-AI interaction, validated methods for operationalizing learning constructs in AI-mediated environments, and empirical insights into how time constraints shape AI-assisted programming behavior.

Keywords

AI-assisted programming, learner behavior modeling, cognitive engagement, time-constrained programming

The increasing integration of generative artificial intelligence (GenAI) tools into programming environments is transforming how learners approach problem solving. AI coding assistants now provide real-time support for code generation, debugging, and explanation, enabling learners to complete tasks more efficiently [4, 14]. While these tools offer clear productivity benefits, their impact on learning processes remains insufficiently understood, particularly in time constrained contexts such as competitive programming, technical interviews, and timed assessments, where learners must balance speed, correctness, and depth of understanding under pressure. Time pressure interacts with AI availability in ways that may fundamentally alter learner behavior. Preliminary evidence suggests that under time constraints, learners shift toward outcome-oriented strategies, using AI to generate or regenerate complete solutions rather than engaging in systematic reasoning [9]. However, these observations are based primarily on self-reports and outcome-based measures. The fine-grained behavioral dynamics of how learners integrate AI assistance into their problem-solving processes - when they seek help, how they transition between independent work and AI-assisted activity, and how they regulate these decisions, remain largely unexamined. This gap is particularly significant for the Educational Data Mining (EDM) community, where understanding learning processes through behavioral data is a central concern [2]. This doctoral research addresses this gap by developing a data-driven approach to modeling learner-AI interaction in programming tasks, grounded in the framework of SRL [16]. The study collects fine-grained interaction logs from computer science students completing algorithmic programming tasks with an AI coding assistant under both timed and untimed conditions. Using process mining, sequential analysis, and clustering techniques, the research aims to characterize AI usage patterns, model temporal dynamics of assistance-seeking, identify distinct learner profiles, and develop validated behavioral proxies for constructs such as cognitive engagement and help-seeking.

2. RELATED WORK

2.1 Learning Analytics in Programming

EDM research has extensively used fine-grained interaction logs, code edits, compilations, submissions, and error events to model learner behavior in programming environments. Techniques such as sequence mining, process modeling, and clustering have been applied to identify problem solving strategies, detect learning patterns, and predict performance [6, 10, 12, 13]. These studies demonstrate the value of be-

havioral data in uncovering latent learning processes beyond final outcomes. However, this body of work assumes environments where learners interact primarily with compilers, editors, and instructional resources. The emergence of AI coding assistants introduces a fundamentally different form of interaction, where learners can offload core cognitive tasks such as code generation and debugging to an AI system, necessitating new analytical approaches that account for AI-mediated actions within behavioral sequences.

2.2 AI-Assisted Programming and Learner Behavior

Recent studies have examined AI coding assistants in programming education, finding that such tools can reduce task completion time and lower barriers to entry, but may also encourage over-reliance, superficial engagement, and reduced opportunities for deep learning [4, 11, 14]. Learners frequently use AI to generate complete solutions or iterate through alternatives, especially under performance pressure [9]. While valuable, these findings are largely based on self-reports, controlled experiments, or outcome-based measures. Comparatively little work captures and analyzes fine-grained interaction traces between learners and AI systems during programming tasks, leaving the micro-level dynamics of how learners integrate AI assistance into their problem-solving processes insufficiently understood.

A growing body of EDM research has begun addressing learning in AI-mediated environments more broadly, emphasizing challenges in representing complex interaction sequences, distinguishing productive from unproductive AI usage, and operationalizing constructs such as engagement and self-regulation from behavioral data [3, 15]. However, these efforts have not specifically examined learner-AI interaction in time-constrained programming contexts, where the interplay between time pressure, AI availability, and learner strategies may fundamentally alter regulatory behavior.

2.3 Research Gap

Prior work has (i) established log-based behavioral analysis as a productive approach to studying programming learning, and (ii) identified the growing influence of AI assistants on learner behavior. However, a critical gap remains in the data-driven modeling of learner-AI interaction sequences, particularly in contexts where time constraints shape decision-making and strategy use. Existing studies do not provide representations that integrate Integrated Development Environment (IDE) actions and AI interactions into unified behavioral traces, nor do they offer validated operationalizations of learning constructs such as cognitive engagement and help-seeking in AI-mediated environments. This research addresses this gap by applying sequential and process mining methods to model learner-AI interaction under both timed and untimed conditions, identifying distinct learner profiles, and developing behavioral proxies grounded in the SRL framework described in Section 4.

3. RESEARCH OBJECTIVES

The research is guided by four objectives, organized progressively from behavioral characterization to construct operationalization.

Objective 1: Characterize learner-AI interaction behaviors using log data — This objective focuses on identifying how learners integrate AI assistance into their programming workflows. By analyzing interaction logs, the study aims to uncover patterns in AI usage, including frequency, timing, and the sequencing of actions such as code edits, compilation, and AI queries. This objective provides the descriptive foundation upon which subsequent analyses are built.

Objective 2: Model temporal and sequential patterns of AI-assisted problem solving — Building on the behavioral characterization from Objective 1, this objective applies process mining and sequential modeling techniques to understand how learners transition between activities such as coding, debugging, and seeking AI assistance, and how these transitions differ under timed versus untimed conditions. The goal is to identify recurring behavioral structures and to examine how time pressure reshapes the dynamics of AI-assisted problem solving.

Objective 3: Identify distinct learner profiles based on AI usage strategies — Learners may differ significantly in how they use AI assistance, ranging from minimal reliance to heavy dependence. This objective aims to group learners into meaningful profiles based on features derived from interaction sequences and aggregated metrics, enabling a comparative understanding of diverse approaches to AI-assisted problem solving and their associations with task performance.

Objective 4: Develop and validate data-driven proxies for learning-related constructs — Direct measurement of constructs such as cognitive engagement and help-seeking is challenging in programming contexts. This objective focuses on operationalizing such constructs using observable behavioral indicators derived from interaction data, and validating these proxies through convergent analysis with self-report measures and qualitative examination of selected interaction sessions. This objective represents the primary conceptual contribution of the research, bridging learning science constructs with computational analysis of learner-AI interaction.

Together, these objectives form a progressive arc from empirical groundwork (Objectives 1-2) through learner variation (Objective 3) to theoretically grounded construct validation (Objective 4).

4. THEORETICAL FRAMING

This research is situated within the theoretical framework of SRL, which describes how learners plan, monitor, and adapt their strategies during problem solving [16]. SRL provides an integrative lens that encompasses two constructs central to this work: cognitive engagement and help-seeking behavior. Rather than treating these as independent constructs, this research models them as observable manifestations of self-regulatory processes within AI-mediated programming environments. Cognitive engagement , the extent to which learners invest mental effort in understanding problems [5], is typically reflected in iterative refinement and systematic debugging in programming contexts. However, AI assistance may shift effort distribution toward faster but less effortful strategies. From an SRL perspective, engagement reflects the learner's monitoring and control processes: whether they

actively evaluate their understanding or passively accept AI-generated outputs. Help-seeking, a key SRL strategy [1], reflects when and how learners seek external support. Prior research distinguishes adaptive help-seeking (targeted and strategic) from maladaptive patterns such as over-reliance or avoidance [1]. In AI-mediated environments, AI queries represent a form of help-seeking whose cost and accessibility differ fundamentally from traditional sources such as instructors or peers, potentially altering regulatory decisions, particularly under time pressure, where learners must balance speed benefits of AI assistance against learning benefits of independent effort. Time pressure introduces an additional regulatory demand that interacts with both constructs. In time-constrained settings, learners must continuously allocate limited time across competing activities, e.g. coding, debugging, testing, and seeking AI assistance, making SRL processes particularly visible through behavioral traces. The temporal distribution of these activities, and the transitions between them, provide a window into how learners regulate their problem-solving process under constraint. This integrated framing directly informs the methodological approach adopted in this research. Specifically, SRL theory motivates the use of sequence analysis to capture regulatory transitions between activities (Objective 2), the operationalization of cognitive engagement and help-seeking through behavioral indicators rather than self-report alone (Objective 4), and the identification of learner profiles that reflect distinct regulatory strategies (Objective 3). By grounding computational representations in SRL theory, this work bridges learning science constructs with data-driven analysis, enabling interpretable modeling of learner-AI interaction in time-constrained programming tasks.

5. METHODOLOGY

This research adopts a data-driven, mixed-methods approach to model learner-AI interaction behaviors in programming environments. The methodology focuses on collecting fine-grained interaction data and applying analytical techniques to uncover behavioral patterns, temporal dynamics, and learning relevant indicators.

5.1 Data Sources and Instrumentation

Data will be collected from undergraduate and early-graduate computer science students engaged in timed programming tasks at an Indian technical university. Participants will be recruited from students with prior coursework in programming and familiarity with AI coding assistants, ensuring a baseline level of competence. A target sample of approximately 60-80 participants is planned across multiple data collection sessions to support meaningful clustering and sequence analyses. Participants will complete a set of algorithmic programming tasks in Python or C++ within fixed time limits (30-45 minutes per task), designed to reflect the structure and difficulty of competitive programming and timed assessment scenarios. Tasks will span multiple difficulty levels to elicit variation in problem-solving strategies and AI usage. To examine the role of time pressure, a subset of sessions will include a comparison condition where participants complete equivalent tasks without strict time constraints, enabling analysis of how time pressure shapes interaction behaviors. The programming environment will be instrumented using a combination of IDE-level logging and AI interaction capture. Participants will use a standard code editor (e.g., VS Code) integrated with an AI coding assistant (e.g., GitHub Copilot or a GPT-based interface), configured to log all interactions. The primary data sources include: (i) IDE Interaction Logs capturing code edits, compilation attempts, execution events, error occurrences, and associated timestamps; (ii) AI Interaction Logs recording prompts submitted by learners, AI-generated responses, acceptance or rejection of suggestions, and the timing of each exchange; (iii) Task Performance Data including task completion status, correctness of solutions, time-to-completion, and number of submission attempts; and (iv) Self-Report Measures administered before and after sessions, including survey instruments for perceived cognitive load, AI reliance, and self-regulated learning strategies, used both for triangulation and for validating behavioral proxies developed under Objective 4.

5.2 Data Representation

Learner interactions will be represented as time-stamped sequences of discrete events, integrating IDE actions and AI interactions into a unified trace. Each learner session will be modeled as an ordered sequence of state transitions (e.g., edit $\rightarrow$ compile $\rightarrow$ error $\rightarrow$ AI query $\rightarrow$ edit $\rightarrow$ submit), preserving both the order and timing of actions. These sequences serve as the primary input for the process mining and Markov modeling described in Stage 1 of the analysis. In addition, higher-level features will be extracted from these sequences to support the clustering and profiling in Stage 2, including transition entropy (capturing regularity of behavior), dominant n-grams (capturing recurring micro-strategies), temporal features (such as mean interaction intervals and time allocation across activity types), and AI dependency ratios (such as the proportion of debugging episodes that involve AI queries versus independent resolution).

5.3 Data Analysis

The analytical approach is organized around three complementary stages, each aligned with specific research objectives.

Stage 1: Sequence and Process Analysis (Objectives 1 and 2) — Learner interaction sequences will be analyzed using process mining techniques, specifically Directly-Follows Graphs and fuzzy mining algorithms implemented in tools such as ProM or PM4Py, to visualize and compare dominant behavioral pathways across learners [3]. Additionally, first-order Markov models will be fitted to learner action sequences to estimate transition probabilities between states such as coding, compiling, debugging, and AI querying. These transition matrices will serve as compact representations of individual problem-solving processes and will be compared across timed and untimed conditions to examine how time pressure alters behavioral transitions.

Stage 2: Clustering and Learner Profiling (Objective 3) — Feature vectors will be constructed for each learner session, combining sequence-derived features (e.g., transition entropy, most frequent n-grams, proportion of time in each activity state) with aggregated interaction metrics (e.g., total AI queries, mean time between AI requests, ratio of AI-assisted to independent code edits). These feature vectors will be used as input to clustering algorithms. Agglomerative hierarchical clustering will be applied initially to ex-

plore the natural grouping structure, followed by k-medoids clustering for robustness to outliers. Cluster validity will be assessed using silhouette scores and domain-informed interpretation. The resulting profiles will be characterized in terms of their AI reliance patterns, temporal strategies, and association with task performance outcomes.

Stage 3: Construct Operationalization and Validation (Objective 4) — Behavioral proxies for cognitive engagement and help-seeking will be derived from interaction data. Cognitive engagement will be operationalized through indicators such as the duration of sustained independent coding episodes, the ratio of self-initiated to AI-delegated debugging, and the presence of iterative refinement cycles. Help-seeking will be operationalized through the timing of AI queries relative to task progression, the specificity of prompts (classified through manual coding of a subsample), and the dependency of subsequent actions on AI outputs (e.g., accepted verbatim, modified, or discarded). These proxies will be validated through convergent analysis with self-report measures and stimulated recall interviews with a subset of participants.

6. WORK DONE SO FAR

The proposed research builds on three preliminary studies. First, a survey-based study of learner perceptions [7] found that learners view AI tools as performance enhancers while expressing concerns about over-reliance, and that they differentiate between practice and evaluative contexts, directly motivating the inclusion of varied task conditions in the proposed design (Section 5.1). Second, an empirical study of AI interaction behaviors during programming tasks [9] revealed outcome-oriented strategies and iterative AI-dependent debugging under time pressure, providing the behavioral evidence that motivates the sequence analysis under Objectives 1 and 2, and generating preliminary interaction traces that will serve as pilot data for the analytical pipeline. Third, an analysis of competitive programming workflows [8] identified fragmented toolchains as a barrier to capturing coherent behavioral data, directly informing the decision to use a controlled, integrated programming environment rather than observing naturalistic but fragmented settings (Section 5.1). Together, these studies provide the empirical foundation , from perceptions through observed behaviors to environmental constraints, upon which the proposed modeling builds.

7. EXPECTED CONTRIBUTIONS TO EDM

This research aims to contribute to the EDM community across methodological, empirical, and conceptual dimensions.

1. **Unified representations of learner-AI interaction** — Existing learning analytics approaches in programming typically model learner interactions with compilers and editors, treating the programming environment as a closed system. This work contributes new representational approaches that integrate AI interactions, prompts, responses, acceptance and rejection of suggestions into unified behavioral traces alongside IDE actions. These representations extend the analytical vocabulary available to EDM researchers studying any environment where learners interact with intelligent systems, not only programming.

2. **Validated behavioral proxies for learning constructs in AI-mediated contexts** — A persistent challenge in EDM is operationalizing theoretical constructs through behavioral data. This research contributes proxies for cognitive engagement and help-seeking that are specifically designed for AI-mediated environments and validated through convergent analysis with self-report instruments and qualitative examination via stimulated recall. By grounding these proxies in the SRL framework and demonstrating their validity, the work provides a reusable methodological template for researchers seeking to measure learning-relevant constructs in settings where AI tools are embedded in the learning process.

3. **Empirical evidence on the role of time pressure in learner-AI interaction** — By comparing interaction behaviors under timed and untimed conditions, this research provides the first controlled empirical evidence of how time constraints shape AI usage patterns, behavioral transitions, and learner regulatory strategies in programming tasks. These findings contribute to a broader understanding of learning under performance pressure and have direct implications for the design of timed assessments in AI-enabled environments, where the interaction between time constraints and AI availability raises unresolved questions about what such assessments actually measure.

4. **Learner profiles for AI-assisted programming** — The identification of distinct profiles based on interaction patterns and AI usage strategies provides a basis for differentiated instructional approaches, enabling researchers and system designers to respond to meaningful variation in how learners integrate AI assistance.

8. FEEDBACK SOUGHT

This doctoral research seeks feedback from the EDM community on four aspects of the proposed work. (1) Sequential modeling choices: whether first-order Markov models and process mining are sufficient to capture learner-AI interaction complexity, or whether higher-order models (e.g., hidden Markov models) or alternative representations (e.g., epistemic network analysis) would be more appropriate, and how to balance model complexity against interpretability. (2) Construct validation: the adequacy of the proposed convergent validation design combining self-report measures and stimulated recall interviews, including guidance on sample size for stimulated recall and whether additional validation sources (e.g., think-aloud protocols, expert coding of traces) should be considered. (3) Productive versus unproductive AI usage: how to distinguish strategic AI use from dependency under time pressure using behavioral features beyond frequency alone, such as prompt specificity, degree of modification of AI output, and timing relative to independent attempts. (4) Generalizability: strategies for assessing whether findings from a controlled programming environment transfer to naturalistic contexts such as coursework and competitive programming.

ABSTRACT

Modern electrical grid systems demand engineers capable of adaptive reasoning, systematic justification, and principled decision-making under uncertainty. However, while many graduates excel technically, they often struggle with these expert-level competencies, revealing gaps in our understanding of expertise development. To address this, we need to identify the granular cognitive and epistemic shifts that occur along the expertise continuum. Drawing on Epistemic Frame Theory, this study examines how epistemic frames shape the developmental trajectory of expertise across second-year, third-year, and final-year undergraduates, compared against field professionals (experts). In the study, participants completed an open-ended electrical grid design task in a computer-based environment. We applied Min-Max normalization to verbal protocols to neutralize verbosity bias and reveal latent structural shifts. Our findings highlight a two fundamental developmental trajectories. An ascending trajectory captures the adoption of a professional lens, wherein students transition from academic idealism to professional pragmatism and from reactive debugging to proactive modeling. Conversely, a descending trajectory reflects the shedding of novice habits, indicating a gradual disengagement from surface-level and trial-and-error strategies. Notably, experts' strategic silence emerged as a marker of proficiency. We observed that experts' silence is a signal of proficiency. The high-frequency behaviors in novices, such as visual monitoring and explicit naming of components, fade away as knowledge becomes tacit. These findings suggest that expertise is defined as much by what is shed (novice habits) as what is acquired (professional lens). These insights suggest that engineering curricula should incorporate earlier authentic practice to bridge the theoretical trap fostering the transition from explicit theoretical rules to implicit professional norms.

Quantifying Effects of New Advanced Placement STEM Courses through LLM-Assisted Dataset Linkage at Scale

Daniela Ganelin
Stanford University
dganelin@stanford.edu

ABSTRACT

In this paper, I present a validated crosswalk of large administrative datasets, created using LLM co-design, which enables cross-dataset institutional analytics and causal inference. Specifically, I document the creation of a replicable crosswalk pipeline to link national public datasets on school demographics and Advanced Placement (AP) offerings. Using the resulting detailed panel on AP access at U.S. schools, I quantify changes in AP access over time by student demographics. I then use quasi-experimental methods to investigate the effects of two large-scale curricular interventions of the last decade: new AP courses in computer science and precalculus. I find that both courses have had large effects in increasing access and participation in AP math and computer science, with largest effects for underrepresented groups including Black and low-income students and the schools that serve them. In line with open science principles, I plan to make the crosswalk, construction code, and detailed national dataset public to enable future research.

Institutional analytics, causal inference, CS education, human-AI collaboration, educational equity

1. INTRODUCTION

Rigorous secondary math and computer science education play a key role in supporting both the global economy and individuals' success [14, 16]. However, in the U.S. and other countries, challenges persist in ensuring broad STEM participation and success, including disparities in course access and participation by race, socioeconomic status, and gender [23].

A key provider of advanced secondary STEM learning is the nationwide Advanced Placement (AP) program, which serves three million students annually. Students take courses at their high schools and then a standardized end-of-year exam administered by the College Board, with qualifying scores earning students advanced standing or credit at many colleges. Historically, AP calculus and CS participation have mirrored broader disparities. In response to these challenges, the College Board has introduced two new, introductory-level AP courses in recent years: CS Principles in 2016-17 and Precalculus in 2023-24 [11, 25]. Each was designed to attract a broader group of students and has launched at scale, with about 1.5 million combined exams to date.

Daniela Ganelin. Quantifying Effects of New Advanced Placement STEM Courses through LLM-Assisted Dataset Linkage at Scale. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) A difficulty in evaluating the effects of these courses and other interventions to increase STEM participation lies in limited national data availability [6]. The College Board has stopped releasing statistics on AP participation, access, and success disaggregated by race and subject [18]. Meanwhile, the last federal data release disaggregating access and participation in AP, calculus, and other advanced courses by subgroup predates the launch of AP Precalculus [23].

In this project, I present a novel LLM-assisted pipeline for joining College Board and federal data from public sources to present a comprehensive look at AP availability in the U.S. by school and subgroup. Validating against administrative data from two states, I show that my crosswalk is more comprehensive, current, and reproducible than the leading existing one. I also join in school-by-subgroup outcome data from Massachusetts, which provides rich publicly available data. In line with open science practices [2], I plan to publicly release the combined data, crosswalk, and generating code, enabling other researchers to study questions related to advanced course access.

Using quasi-experimental causal methods, an emerging area of interest in EDM [3], I evaluate the effects of the two national-level AP curriculum interventions. Nationally, at the institutional level, I find that AP CS Principles and Precalculus had substantial effects on increasing AP math and CS availability, especially for schools serving more Black or low-income students. Additionally, offering CS Principles built a pathway to later offering the more advanced AP CS course. In Massachusetts, I find that both courses substantially increased AP STEM participation, exam passing, and college-preparatory curriculum completion, especially among Black, Hispanic, and socioeconomically disadvantaged students. These results replicate my previous CS Principles results and extend them to the national level, richer outcomes, and a new subject area [13].

I anticipate this project contributing to the EDM community by providing a rich source of open data, a model for AI-assisted dataset construction that enables at-scale institutional analytics using public administrative data, and causal evidence on a national curriculum intervention that is currently improving CS learning outcomes at scale.

2. DATA PIPELINE CONSTRUCTION WITH AI ASSISTANCE

In this section, I describe the process of using LLM assistance to link large-scale administrative datasets, specifically the Common Core of Data and the College Board AP Ledger.

I begin with annual school demographics and directory data for all public schools that ever enroll Grade 9-12 students between 2007-08 and 2024-25 from the federal Common Core of Data (CCD) [22]. The dataset includes 39,609 schools that enroll a total of 270 million Grade 9-12 students.

From the College Board (CB) AP Course Ledger [7], I obtain comprehensive yearly records of audited AP course offerings at 23,435 U.S. schools, including private schools, between 2007-08 and 2025-26. I also obtain CB codes for an additional 26,229 institutions, which I code as never having AP.

Next, using LLM assistance, I construct a CCD-to-CB crosswalk to match schools across the two datasets using school names, addresses, and GPS coordinates, which are included in each data source. For efficiency and reproducibility, the LLM is not used directly to assess each match's quality, as in previous work [19]. Rather, Claude Code (Opus 4.6) co-designs, documents, and implements a fuzzy matching logic algorithm. The approach is designed to capture schools that change names, move addresses, or change CCD codes over time, which can cause one dataset's records to differ from the others.

First, the matching algorithm normalizes school addresses and names (for example, resolving "Middle" vs. "Junior High"), including historical information. Next, it constructs an address index and assesses candidate CCD-to-CB matches using two primary strategies. One strategy considers a CCD and CB school pair to match if they share a normalized address and name similarity, defined by Jaccard and SequenceMatcher, exceeds a threshold. The second strategy defines a match of a pair within a shared geographic block if the combined similarity of name and address, considering both string similarity and geographic distance, exceeds a threshold [21]. Finally, it resolves conflicts where multiple CCD schools share a single CB code by classifying them as "false positives", in which case a worse-matching school loses its assignment; "horizontal composites", involving a sub-school at the same address; and "vertical composites", where a new CCD school takes over enrollment from a previous one for subsequent years.

Matching approaches, thresholds, and implementation details are adjusted through iterative discussion of the 494 schools in Massachusetts until all disagreements with manually verified matchings are resolved. For example, validating against external sources, I identify both correct and incorrect matches among school pairs that share an address but not a name across datasets. To distinguish these cases, Claude designs and constructs a "recent rename bridge" that checks a historical list of names and CB codes to resolve the discrepancy [4]. The AI-assisted process enables rapid construction of a nontrivial matching algorithm that handles a broad variety of special cases and works at national scale, while requiring researcher inspection of only a small sample of each case type. The resulting crosswalk code runs on a MacBook Pro in about two hours. By contrast, the best previous publicly available crosswalk relies in part on a less precise name and ZIP-based matching, and in part on manual searches by Mechanical Turk workers [10, 20]. My crosswalk code is also fully replicable: future researchers can easily recreate all matches and extend to additional data, such as future years, without needing crowdsourced labor, model inference, or state-specific datasets.

My national crosswalk matches 27,866 CCD codes to CB codes, encompassing 97% of total Grade 9-12 enrollment. Comparing my matches to the pre-existing Davenport crosswalk, which provides CB codes for 20,625 of the CCD schools, I find 18,930 cases in which my crosswalk agrees, 914 cases in which Davenport codes do not appear in College Board data (i.e., defunct or mistaken codes), and 781 other cases where my crosswalk disagrees with or excludes a Davenport match. Importantly, my crosswalk introduces matches for 8,817 previously unmatched schools.

I validate the crosswalk by comparison to administrative data available from two states. In Colorado, among 512 schools that are in the CCD universe and have a non-defunct CB code in administrative data, my crosswalk has 481 correct and 6 incorrect matches, while Davenport has 431 correct and 5 incorrect [8, 15]. In Illinois, among 848 schools in the CCD universe with an administrative CEEB code, I have 793 correct and 7 incorrect matches, while Davenport has 697 correct and 11 incorrect. Overall, my crosswalk matches 94% of schools in these two states, with 99% of matches correct. The results sat an LLM-assisted crosswalk can enable dataset linkage with higher efficiency, accuracy, and coverage than human-implemented approaches.

3. PATTERNS OF AP AVAILABILITY

The crosswalk enables construction of a detailed panel dataset of AP availability at U.S. schools by year and subject joined with demographic information, which I use to characterize patterns of AP availability over time. While I focus on in-person math and computer science courses, other researchers could use the same dataset to investigate other subjects or virtual course-taking.

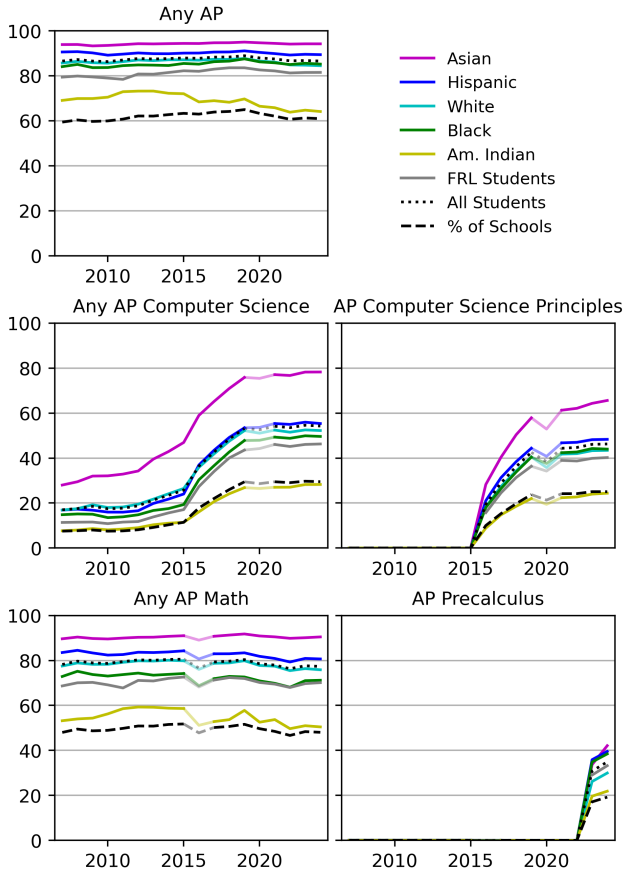

Figure 1. Percent of students nationally who have access to AP, by year (fall-indexed) and subgroup. Colored lines show the portion who attend a school offering each subject, among Grade 9-12 students who attend a regular high school. The gray line shows access among any-grade students who attend a regular high school and qualify for free or reduced-priced lunch. The dashed black line shows the percent of regular high schools that offer AP. Transparent segments mark years in which certain subjects' CB ledger data are incomplete.

I filter the CCD data to 23,487 regular high schools that serve Grades 10-12, merging vertical composites and excluding horizontal sub-schools as well as alternative, special-education, vocational, and virtual schools. These schools enroll a total of 252 million Grade 9-12 students between 2007-08 and 2024-25. Using the crosswalk, which assigns a CB code to 86% of these schools covering 98% of the students, I join school demographic information from CCD with AP records. This allows me to calculate the portion of students nationally who have access to AP by subgroup or school characteristic, subject, and year.

Figure 1 shows patterns of access to CS and math AP over time. While overall AP and AP math access have remained flat over time, access to Precalculus, CS Principles, and CS in general have all grown dramatically. Across all subjects, Asian students have much higher AP access than average and Hispanic students somewhat higher. Meanwhile, poor, Black, and especially American Indian students are less likely to have AP access – except in Precalculus, which disproportionately reaches Black students. Additional results show that AP offerings are higher at larger, urban, and suburban schools. I also find that most of the schools that adopted AP math or CS in recent years used one of the two new courses as their "gateway" course.

4. EFFECTS OF NEW COURSES ON AP AVAILABILITY

4.1 Methods

I demonstrate the applicability of the joined national dataset to policy analysis by examining the effects of schools beginning to offer AP CS Principles or Precalculus. At the national level, I estimate the effects of the new courses on AP offerings across the curriculum. I use a quasi-experimental design that compares changes at treated schools (i.e., schools that take up one of the two new courses) to changes at similar untreated control schools. My primary method is synthetic difference-in-differences (SDID), which weights units and pre-treatment time periods to eliminate bias due to unobservable latent factors [1]. Because SDID requires a balanced panel, I narrow the sample to the 15,799 schools that report Grade 9-12 enrollment in each year between 2007-08 and 2024-25, for a total of 231 million. I verify model fit using event studies and find similar results when varying specifications, e.g. including covariates, using a shorter panel, or using CSDID estimators on the unbalanced panel [5].

4.2 Results

Table 1 shows that both new courses have a substantial effect in opening the door to AP STEM access. Effects are larger for higher-poverty, smaller, and rural schools. Effects are particularly large for CS Principles, which triples the portion of schools offering any AP CS relative to later-treated schools' baseline. Additionally, offering CS Principles increases the chance of a school offering AP CS A, the pre-existing and more advanced, Java-focused AP course. Event study evidence shows that this growth comes primarily in the year *after* CS Principles is first offered, suggesting that CS Principles prepares schools to later build an extended CS pathway. By contrast, Precalculus has minimal impact on Calculus, neither substituting for nor expanding its offerings. However, it has greater effects on expanding AP math access at schools with more Black students.

Table 1: SDID Estimates of Effects on AP Course Offerings

	AP CS Principles		AP Precalculus	
Outcome	**Effect**	**Baseline**	**Effect**	**Baseline**
Any AP	0.06***	0.93	0.05***	0.97
	(0.01)		(0.01)	
Any AP Math or CS	0.10***	0.84	0.10***	0.90
	(0.01)		(0.01)	
Any AP CS	0.50***	0.26	0.05***	0.59
	(0.02)		(0.01)	
AP CS A	0.13***	0.26	0.02***	0.39
	(0.00)		(0.00)	
Any AP Math	0.03***	0.84	0.12***	0.88
	(0.01)		(0.01)	
Any AP Calculus	0.03***	0.82	0.02***	0.84
	(0.00)		(0.01)	
Schools	*15,799*		*15,799*	
Treated	*6,374*		*4,254*	

Notes: Estimated effects of offering new AP STEM courses on AP availability using a national balanced panel, 2007-08 to 2025-26. Baseline columns show the mean value among later-treated schools in the year before first treatment: 2015–16 for CS Principles, 2022–23 for Precalculus. Clustered bootstrap SEs in parentheses. *** $p<0.01$

5. EFFECTS ON STUDENT OUTCOMES

5.1 Methods and Data

Next, I estimate the effect of a school offering the new courses on student outcomes. I extend my data linkage pipeline by further incorporating rich school-level outcome data made publicly available by the Massachusetts Department of Elementary and Secondary Education (DESE) for 2007-08 to 2024-25 [17]. Matching is enabled by state-level school identifiers provided in CCD. Outcomes include by-subject AP exam participation and (partially suppressed) performance records, as well as completion rates of MassCore, a set of college-ready course requirements used for University of Massachusetts admission [24]. All outcomes are disaggregated by school, year, subject, and student subgroup. Critically, these outcomes are college-proximate: passing AP scores and MassCore completion are direct links to college admissions and credit earning.

I use a similar methodology to the national pipeline, using a balanced sample of 283 schools that appear in DESE data and have Grade 9-12 enrollment in each year.

5.2 Results

Preliminary results (Table 2) show the new courses substantially increase AP participation, each causing an annual increase of over 20 exams in the relevant subject area. Subgroup-specific results show that effects are particularly large relative to baseline for Black, Hispanic, and High Needs (e.g., low-income or English Learner) students, as well as female students for CS Principles. For these subgroups, CS Principles more than quintuples CS participation over time relative to baseline, and Precalculus expands math participation by over 70%.

Neither course clearly expands or substitutes for participation in the corresponding more advanced course. However, both courses have some positive effects on exam passing: Precalculus increases AP Calculus passing, suggesting that the course increases students' mathematical preparation. Meanwhile, CS Principles triples a school's probability of having at least 10 passing scores on AP CS exams, relative to a baseline of 13%. Additionally, AP CS Principles has a large and increasing effect on growing AP participation across the curriculum, while Precalculus seems to instead partially

substitute for non-STEM AP courses. Both courses also seem to increase MassCore completion, although these results are not always robust against alternative specifications (e.g., shorter panels). I plan to investigate patterns of heterogeneity and alternative estimation methods, as well as techniques for handling suppressed data.

Table 2: SDID Estimates of Effects on Student Outcomes

	AP CS Principles			AP Precalculus		
Outcome	**Exam Count**	**Base**	**10+ Pass**	**Exam Count**	**Base**	**10+ Pass**
All AP	51.7***	365	-0.00	18.9*	390	-0.02
	(15.2)		(0.02)	(10.3)		(0.02)
All AP CS	21.4***	7	0.25***	-2.9	24	0.06
	(2.1)		(0.03)	(2.6)		(0.04)
AP CS A	0.1	7	0.04*	-0.1	7	0.01
	(0.8)		(0.02)	(0.7)		(0.03)
All AP Math	5.0*	64	0.02	26.8***	55	0.21***
	(2.9)		(0.03)	(3.6)		(0.06)

Schools	283			283		
Treated	184			88		

Notes: Estimated effects of offering new AP STEM courses on student outcomes using a Massachusetts balanced panel, 2007-08 to 2025-26. MassCore starts in 2008-09 and uses a smaller subsample of 266 schools which have reported values in all years. The measure of exam passing is binary - i.e., at least 10 students earned a 3, 4, or 5 – to avoid small-count data suppressions. Baseline columns show the mean value among later-treated schools in the year before first treatment: 2015–16 for CS Principles, 2022–23 for Precalculus. Clustered bootstrap SEs in parentheses. *** $p<0.01$, ** $p<0.05$, * $p<0.10$.

6. CONCLUSIONS

In this paper, I demonstrate a process for using LLMs to build replicable, validated linkage pipelines across large, public administrative educational datasets. A similar process would allow discovery of connections across additional education domains [12].

Using the pipeline, I construct a novel dataset covering AP offerings at nearly all U.S. regular public high schools from 2007-08 to the present. I use this dataset, as well as rich student outcome data from Massachusetts, to examine the effects of two new courses: AP CS Principles and AP Precalculus. Using causal methods, I show that both courses have had large effects in expanding and broadening AP math and CS access and participation, helping build a diverse STEM pipeline for the future.

The results also suggest the power of a new opportunity in shifting school culture towards advanced learning in CS and other subjects. CS Principles was explicitly designed to broaden participation in computing as a large NSF-funded initiative including teacher training, extensive partner-led curriculum development, and a creative project component in assessment [9]. My results suggest that when schools introduce it, they do more than register students for the course: they build a pipeline to offering more advanced CS learning opportunities in the future, bring in previously underrepresented groups, grow AP participation across the curriculum, shift to becoming schools with high AP CS pass counts, and encourage completion of a college-ready curriculum.

AP Precalculus may yet achieve similar effects. I hope that the crosswalk, AI-assisted methodology, and compiled contextualized, granular administrative data that I share through this project will help researchers in studying the effects of this policy and other large-scale educational interventions.

ABSTRACT

This study designs, implements, and evaluates an AI-based discussion facilitation agent that promotes critical thinking in graduate courses by detecting cognitive presence (CP) in real time. Grounded in the Community of Inquiry (CoI) framework, the agent embeds a fine-tuned RoBERTa transformer model (trained on 17,627 human-coded MOOC sentences; macro-F1 ≈ 0.70) into live graduate-level online discussions. The system classifies each student post into one of four CP phases—Triggering, Exploration, Integration, or Resolution—and immediately generates theory-informed, formative prompts to scaffold learners toward deeper inquiry. A design-based research methodology is used to iteratively refine the model and evaluate its pedagogical impact in instructional design courses. Three research questions address model accuracy, student and instructor perceptions of utility, and technical and pedagogical feasibility. Expected contributions include an interpretable NLP approach to CP detection, a replicable blueprint for real-time AI scaffolding, and empirical evidence that automated nudges can elevate online discourse beyond the Exploration plateau commonly observed in CoI studies.

Keywords

Cognitive presence, Community of Inquiry, AI agent, natural language processing, real-time scaffolding, online discussion

1. INTRODUCTION

Cognitive presence (CP) is defined as the extent to which learners construct and confirm meaning through sustained reflection and discourse, and is a central component of the Community of Inquiry (CoI) framework [1]. CP develops through four phases of practical inquiry: Triggering Event, Exploration, Integration, and Resolution. Together, these phases describe how critical thinking can emerge in online and hybrid learning environments.

Across two decades of CoI research, a consistent pattern has been reported: most student posts remain at the Exploration phase, and few reach Integration or Resolution [3, 4]. The pedagogical implication is that online discussions often underdeliver on their critical-thinking promise. Prior work suggests, however, that this pattern is responsive to instructor facilitation. When instructors actively guide students to synthesize and resolve, learners do advance to higher CP phases [2]. The difficulty is that such facilitation is hard to sustain in courses with many discussions and many students. Instructors have limited time, and most posts do not receive immediate, individualized guidance in the moment of writing.

In parallel, recent advances in natural language processing (NLP) have made automated CP classification feasible. Transformer-based models can label CP phases with accuracy that approaches human coders [3, 5]. Our prior work fine-tuned RoBERTa on 17,627 human-coded MOOC sentences and reached macro-F1 ≈ 0.70. These classifiers, however, have been used mainly for retrospective analysis of completed courses rather than for supporting learners as they write. The pedagogical potential of CP detection—using it to actually influence discourse in the moment—remains largely untested.

This study addresses that gap. It embeds a validated CP classifier in a live AI discussion agent that monitors graduate-level discussion forums, classifies each new post in real time, and returns immediate, gentle, theory-grounded prompts intended to encourage deeper inquiry. The study examines whether such real-time scaffolding can move student posts toward Integration and Resolution, and under what technical and pedagogical conditions this is feasible.

This study is guided by three research questions:

- **RQ1 (Accuracy):** How reliably can the AI agent classify discussion posts into CP stages compared to human coders? We will benchmark the model against expert-coded data using F1 and Cohen's κ.
- **RQ2 (Utility):** How do students and instructors perceive the agent's real-time prompts? Do they find the feedback clear, timely, and helpful for deepening discussion? Surveys and interviews will gauge acceptability and usefulness.
- **RQ3 (Feasibility):** What technical and pedagogical challenges arise in deploying this real-time agent? We

will examine integration with learning platforms, system responsiveness, instructor workload, and any unintended effects on discourse dynamics.

This project makes three interrelated contributions to the EDM and AIED communities. Theoretically, it extends the CoI framework from a retrospective coding scheme into an automated real-time in- tervention, demonstrating how a well-established learning theory can be operationalized in an AI system. Methodologically, it demonstrates an explainable transformer NLP approach—aug- mented with SHAP analyses and CoI-theoretic features—that makes model decisions transparent and trustworthy for educational stakeholders. Instructionally, it offers a concrete blueprint for deploying real-time AI scaffolding in online and hybrid graduate courses, with documented lessons on integration, usability, and pedagogical impact. By anticipating that real-time CP nudges will increase the propor- tion of Integration/Resolution posts and that students will perceive the agent positively, this research also builds empirical evidence for the promise of AI-driven formative feedback in higher education. Findings will be disseminated to both technical (EDM/AIED) and educational (Learning Sciences, instructional design) communities, reinforcing the interdisciplinary spirit of the EDM conference

2. RELATED WORK

This study draws on two lines of prior research: empirical CoI work on cognitive presence in online discussions, and NLP work on automated CP detection. We review each below before identifying the gap that motivates this study.

2.1 The Exploration Plateau in CoI Research

The CoI framework conceptualizes meaningful online learning as the interaction of social, teaching, and cognitive presence [1]. Empirical CP research consistently reports that discussion contributions concentrate at the Exploration phase, with relatively few posts reaching Integration or Resolution [4]. Facilitation is identified as the primary driver of advancement: when instructors explicitly guide students to resolve problems, participants do progress to higher CP phases [2]. Two implications follow. First, the Exploration plateau is not absolute; it responds to deliberate scaffolding. Second, scaffolding of this kind has so far been documented mainly in small, instructor-intensive settings, where post-by-post facilitation is feasible.

2.2 Automated Detection of Cognitive Presence

A parallel line of work uses NLP to automate CP classification. Transformer architectures, such as BERT and RoBERTa, have achieved strong performance on educational text classification tasks. [3] introduced MOOC-BERT for automated phase labeling. [5] extended this line with annotation-guideline-based knowledge augmentation for educational text classification. [2] report that GPT-class large language models can approximate human coders on CP content analysis. Our prior work fine-tuned RoBERTa with embedded CoI features and reached macro-F1 ≈ 0.70; the same analysis also revealed a correlation between higher-order CP posts and downstream outcomes including grades and self-reported knowledge transfer.

2.3 The Gap This study Addresses

Although both lines of work are well developed, they have rarely been combined. The CoI facilitation literature shows that scaffolding can move learners beyond Exploration but does not scale to the post level. The NLP literature shows that machines can detect CP reliably but has used detection almost entirely as a post-hoc analytic tool. To our knowledge, no prior study has embedded a CP classifier in a live discussion environment to provide real-time, theory-grounded prompts to students as they write. This study is positioned at exactly this intersection: it asks whether automated, in-the-moment CP scaffolding can support the kind of advancement toward Integration and Resolution that human facilitation can produce but cannot sustain at scale.

3. METHODOLOGY

This project employs a design-based research (DBR) approach, iteratively developing the AI agent and testing it in authentic classroom settings, then refining the model and prompts based on real classroom feedback. The work comprises two interlocking components.

3.1 Model Refinement

We begin with an existing transformer classifier (RoBERTa fine-tuned on MOOC data with embedded CoI features). To adapt it to graduate seminar discussions, we apply transfer learning: initializing from MOOC-trained weights, then retraining on a smaller set of manually coded graduate-level posts. Approximately 20% of collected posts will be double-coded by experts to create a gold-standard test set. Model performance will be evaluated using precision, recall, and F1 for each CP category, along with inter-rater agreement (Cohen's κ) between model and human coders. Shapley Additive Explanations (SHAP) analyses [6] will be used to identify the linguistic features driving classification decisions, rendering the model interpretable to both technical and educational audiences.

3.2 AI Agent Development

The refined classifier is embedded into an interactive agent within the learning management system (LMS) or chat platform. During weekly forum activities, the agent listens for new posts. When a student submits a contribution, the agent immediately classifies it into a CP phase and generates a tailored, formative prompt. These prompts are co-designed with instructors and grounded in CoI theory. For example, if a post is rated as Exploration, the agent might respond: *"You have shared some great ideas. How might these connect to other concepts we have covered?"* If a post is already at the Integration level, it might offer: *"Nice synthesis of ideas. Can you take this further by applying it to a real-world problem?"* Crucially, prompts are phrased as open questions, not evaluations, and students are free to revise their post or ignore the suggestion with no grading penalty. Instructors have oversight through a dashboard that logs each classification and can disable or customize feedback as needed.

3.3 Evaluation Design

The AI agent will be deployed in several graduate instructional design courses over a semester (approximately six discussions per course, targeting roughly 300 posts in total).

Data collection from Fall 2025 (without the CP-supported agent) will serve as a baseline comparison. The agent-supported implementation is planned for Fall 2026. Both quantitative and qualitative data will be collected: system logs will capture processing time, uptime, and integration issues (RQ3); post-semester surveys will assess student perceptions of clarity and helpfulness (RQ2); and semi-structured interviews will probe student and instructor experiences in depth (RQ2–RQ3). Model accuracy metrics will be computed against expert-coded samples (RQ1).

ABSTRACT

The benefits of explanations and feedback on learning are well established. However, delivering effective feedback at scale remains a substantial challenge due to various logistical and cost-related constraints. This paper reports on my randomized controlled trials (RCTs) evaluating the effectiveness of AI-generated content for middle school mathematics. My first studies include RCTs comparing AI-generated explanations and feedback with business-as-usual (no support), as well as AI-generated content with teacher-written content. Both used a similar pipeline to generate feedback, going through an iterative prompt engineering process with experienced educators, followed by LLM-as-a-judge and a limited human review. One RCT found that students receiving AI-generated feedback were 16% more likely to correct their current answer and 7% more likely to succeed on the subsequent problem. I then moved to live content generation, with LLMs providing feedback to short-answer math problems. I used a cross-over design to find the impact of using GPT-4o to provide short, long, or affective feedback, and also analyzed a model fine-tuned on teacher-written feedback. I found affective feedback was the only feedback that was consistently helpful in both the short- and medium-term transfer learning for students. This informs my future research, aiming to generate and cache various styles of content using LLMs, then personalize it to students' learning characteristics. My future work builds on this by aiming to personalize the style, length, and tone of feedback to students at scale based on both student and misconceptions features at scale, which no prior work has managed to achieve.

Large Language Models (LLMs) are increasingly deployed in educational contexts for tasks such as chatbots [21], feedback generation [24], and question generation [13]. However, equally important to creating these systems is evaluating their effectiveness and fairness. LLM-generated content needs to be grounded in pedagogy and delivered effectively, otherwise it risks decreasing critical thinking by removing the opportunity for productive struggle [4]. However, if implemented effectively, it can personalize content such as on-demand support, feedback, and more.

Given the risks and potential of LLMs, my focus has been on using established pedagogical techniques and advanced prompt engineering to generate content at scale before empirically demonstrating the effectiveness. Working with the ASSISTments platform [8], I have conducted RCTs using AI-generated content with tens of thousands of students in grades 6-8, Illustrative Math. Using techniques such as RAG [12], few-shot prompt [2], LLM-as-a-judge [27], and chain-of-thought [22], I have generated on-demand supports to aid students, which had previously been an expensive and time-consuming effort requiring the recruitment of teachers, who themselves are limited in time. This has informed my research into how LLMs can be used to scale content in digital learning platforms (DLPs) at an affordable and unprecedented rate. I am now working to generate various styles of content, which, with the correct bandits algorithm, aims to provide personalized content on a new level.

My works so far has scaled on-demand explanations and feedback. Explanations are a form of instructional support that provides all the steps necessary to walk through a solution to a problem, often presented as step-by-step solutions. They are well-established as effective tools for student learning [20, 17]. Notably, explanations are more effective for students with less expertise than their higher-skilled peers as described by the "expertise reversal effect" [9]. One major theory for why explanations are helpful for all students, but particularly helpful for low-performing students, is cognitive load theory [18], which posits that explanations reduce the mental effort required to process information, thereby allowing students to focus their cognitive resources on acquiring and remembering mathematical knowledge.

The other content I've been working to generate, feedback, is among the most effective instructional interventions documented in the learning sciences [6, 7]. Meta-analyses consistently show that well-designed corrective feedback supports

error detection, improves problem-solving strategies, and promotes self-regulation, particularly for lower-achieving students [23, 10]. Despite this evidence, delivering personalized feedback at scale remains a persistent challenge in digital learning platforms (DLPs). Prior approaches using crowdsourcing have shown promise but suffer from quality variability [15, 5]. Recent advances in large language models (LLMs) present a new opportunity. LLMs can generate coherent, context-sensitive feedback at low marginal cost. However, whether AI-generated feedback improves learning outcomes over no feedback—and for which students—remains an open empirical question with limited large-scale evidence in authentic classroom settings.

This informs my three main research questions for my last studies. **Research Plan 1** investigates "Under what conditions does feedback style moderate learning outcomes in middle school mathematics?" This aims to analyze the impact of various feedback styles inspired by Hattie & Timperley [6] and which works best by looking at student characteristics and classifying wrong answers. With sufficient data, this will enable **Research Plan 2**, which asks "Can a bandit or similar algorithm effectively personalize feedback style for students in a live DLP, and what student features are necessary to do so?" This investigates personalizing at scale within ASSISTments, which requires understanding students and constantly measuring learners' characteristics and updating latent student traits [19]. Lastly, moving to a more dynamic setting, **Research Plan 3** asks "Does personalized LLM-generated feedback on open-ended responses improve learning outcomes compared to no feedback, and does it do so sustainably over a full academic year?" Open-ended problems are very important as they promote deeper and more critical thinking, but scaling personalized feedback for tens of thousands of students can be expensive.

2. PUBLISHED WORKS

During my PhD, I have published several works on my various studies, aiming to generate and evaluate the effectiveness of content. I have first-author submissions to both Learning at Scale [25] and AIED [24] and an under-review submission at Learning at Scale this year.

Studies 1 & 2: Scaling Static Explanations and Feedback [25, 26]. In these works, I have empirically evaluated the effectiveness of LLM-generated explanations and static feedback messages through RCTs in ASSISTments. For these RCTs, I collaborated with former teachers, curriculum designers at ASSISTments, as well as other PhD students within my lab, to engineer effective prompts for explanations and feedback, before caching them in the ASSISTments database and engineering the middleware needed to randomly select the LLM-generated content, which was displayed to students as shown in figures 1 and 2. These studies have been run *en vivo* in ASSISTments by randomly selecting to deliver nothing, LLM-generated content, or teacher-authored content, and comparing their effectiveness, with tens of thousands of students. To analyze our results, I used multiple mixed-effects linear and logistic regression models with various outcome metrics. Our results were consistent across the studies: LLM-generated content was better than nothing, and there was no reliable difference between LLM-generated content and teacher-authored content. Also consistent with the expertise reversal effect, I found these supports were more effective for lower-knowledge students. Given the incredibly cheap cost of scaling this content with LLMs (about 5 cents per content), I feel this confirms that LLMs can aid students by scaling content without harming student performance.

Study 3: Scaling Feedback Generation in a Live Setting [24]. While scaling static content is valuable as done in **studies 1 & 2**, providing dynamic feedback to short answers is equally valuable. For **study 3** I worked with ASSISTments to engineer a student interface that could deliver feedback when they submit short-answer responses to open-ended problems. Prior to our work, of the 50 million instances of students submitting a short-answer, non-computer-gradeable response in ASSISTments, only 1 million (2%) actually received feedback, and often 2-3 days later. As such, I am laying the groundwork for ASSISTments to provide short-answer feedback at scale.

In this study, along with collaborators at WPI and the ASSISTments foundation, I recruited 11 teachers with a total of 322 students, and employed a crossover design to evaluate the effectiveness of LLM-generated feedback of various styles, short feedback, long feedback, affective (self-level) feedback, or feedback from a model which was fine-tuned on teacher-written feedback in my prior work [1]. Our findings suggested that only affective feedback was useful to students in both the next-problem and medium transfer range, whereas other feedback styles had minimal help, or harmed student learning due to giving away excessive information and removing the opportunity for productive struggle. This was a surprising result, given that affective supports are generally thought to be ignored by students in DLPs. However, it also inspires my future work on providing personalized feedback to all students, so that students who benefit more from a specific feedback style receive that personalized feedback.

3. ONGOING WORK

I intend for this to be the main component of my dissertation. Having shown LLMs can generate effective content, I aim to generate personalized content at scale. This involves three studies, the first of which is an RCT aiming to explain when different styles of feedback are useful, and the second, which aims to personalize in a live setting using a bandit's algorithm [16], and the last, which repeats this for open-response questions.

Research Plan 1 & 2. This study, which has already started, aims to build upon my prior work generating wrong answer feedback for students with LLMs. I found LLM-generated feedback was effective; however, inspired by Hattie & Timperley's styles of feedback [6], I have generated 6 styles of feedback: Feedback; Feed-up; Feedback & Feed-up; Feedback & Self-regulation; Feedback, Feed-up & Self-regulation; and Self-level feedback. These feedback styles differ in the type of information provided, such as whether a small hint is given, whether self-regulatory behavior is encouraged, or whether the feedback is affective. The goal is to determine which type of feedback works best, and answer "when?" and "why?".

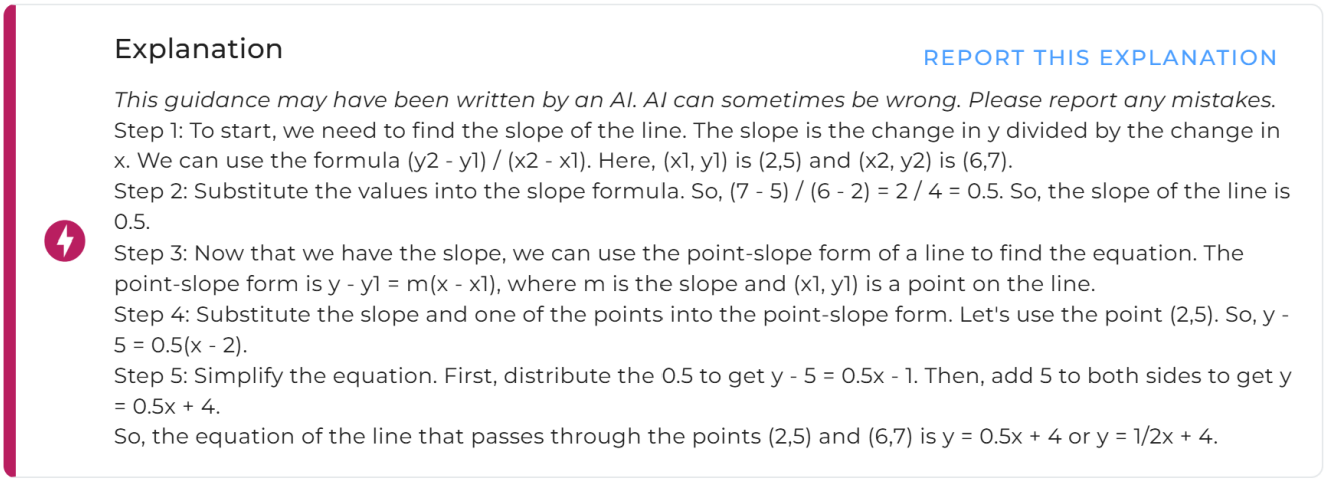

Figure 1: An example explanation with the report button and warning message.

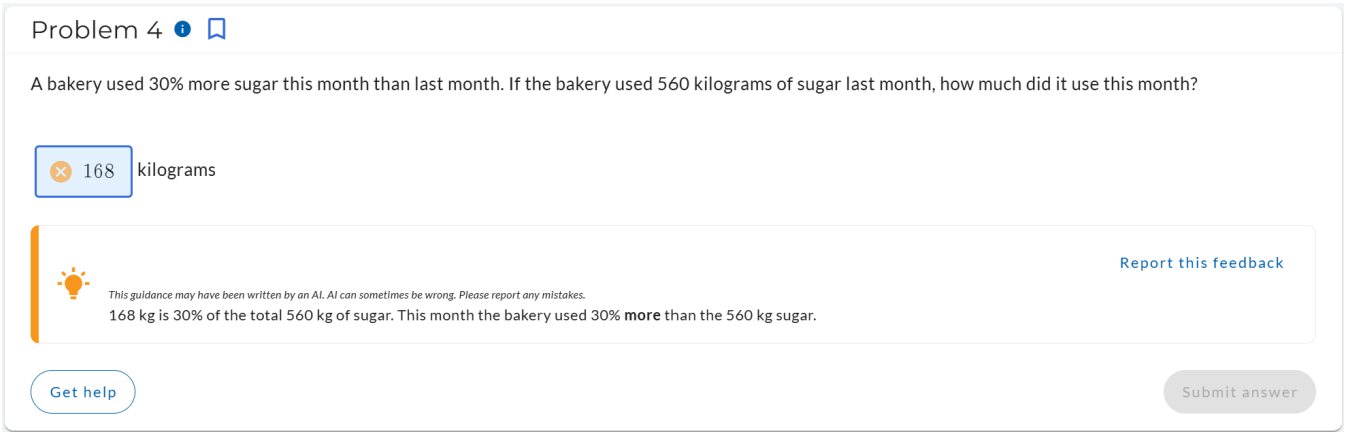

Figure 2: An example feedback message as it appears in ASSISTments.

The "when?" refers to different types of wrong answers and student characteristics. For instance, for the problem **"A bakery used 30% more sugar this month than last month. The bakery used 560kg of sugar last month. How much did it use this month?"**, I hypothesize that the best style of feedback for a student who said "168" (forgot to add it to the original amount) will be very different from the best type of feedback for a student who said "590" (does not understand percentages). For the student who answered "168", I hypothesize self-regulatory feedback, which emphasizes that reading the problem carefully will best help the student, whereas for the student who answered "590", a combination of feedback and feed-up will best guide them towards a better understanding of percentages. The same can be true for student characteristics. Reinforcement learning has shown that incorperating student features into a bandit model can improve learning outcomes, which I intend to do once I have collected sufficient data [11].

As mentioned, my first research project comparing the styles of feedback is currently running, however, I could use guidance on the analysis plan. I hypothesize that the key to understanding which styles of feedback are helpful, and when, is categorizing styles of misconceptions into different types. Categories such as "forgot last step", "conceptual misunderstanding", "procedural error" or more may reveal deeper insights into when each style of feedback may be more or less helpful. Determining which categories to include and how to classify them is a challenge I am facing. However, there are other approaches I have considered. Using Bayesian Knowledge Tracing or a similar algorithm to classify a student's knowledge of various topics, or even their individual slip rate, appears feasible based on prior research [14], which could inform both analysis and bandits models, which is my second project relating to this work. However, defining the best methodological approach and analysis plan has been a difficult task for me, and I would appreciate the insights of experienced researchers in the field to improve and solidify this methodology.

Research Plan 3. Building on my feedback research, my other work involves generating dynamic feedback using LLMs for open-response problems. These are problems that require students to type 1-3 sentences to answer a question,

as opposed to fill-in problems, which require a number or short expression. This makes caching feedback infeasible, and before LLMs, attempts to scale feedback proved expensive and difficult [3]. However, in a live, undefined setting, I have more options for how I might generate feedback. I may generate feedback, feed-up, self-regulation, and affective feedback as in **Study 1**. However, by being able to see, rather than just infer, a student's work, I can go beyond basic feedback. I may provide targeted interventions, such as providing sentence starters or clarifying specific portions of answers. I have worked with ASSISTments and we intend to enable this feature for 50% of teachers beginning in the fall of 2026 and lasting for the complete 2026-2027 school year. This will include around 500 teachers with tens of thousands of students in the study.

This work will include building on my prior work (**Study 3**)by opening new opportunities for longitudinal analysis. This will analyze the effect of repeated interactions over the course of the school year. I will analyze whether there are diminishing returns, increased disengagement, or increased unproductive behavior (such as gaming) as a result of adding LLM-feedback to ASSISTments. Alternatively, I will be able to investigate whether there is a cumulative advantage or other sustained learning improvements for students who receive feedback on their open-ended questions. Last, I hope to gather sufficient data to fine-tune a custom LLM to generate feedback for students in ASSISTments, as I have done in prior work [1].

4. CONCLUSION

Personalizing feedback for students at scale remains a consequential and open problem in educational data mining. While the learning sciences have long established that feedback is among the most effective instructional interventions, we have lacked both the tools to deliver it affordably at scale and the empirical understanding of when different feedback styles are most effective. My completed work addresses this using three large-scale RCTs across 250,000 observations and 50,000 students, which demonstrate that LLM-generated content is effective and cost-effective. My remaining work addresses a harder yet more impactful problem. Categorizing student misconceptions is a prerequisite for understanding the causal structure of feedback effectiveness. If we cannot distinguish a student who made a procedural slip from one with a conceptual misunderstanding, we cannot know which feedback style to deliver, nor why it worked when it did. This represents a contribution to the EDM and learning science community beyond ASSISTments: a framework for misconception-aware feedback personalization that can inform how any DLP reasons about learner state. Combined with a bandit-based personalization system and longitudinal data from tens of thousands of students, this work aims to produce a large-scale empirical study of personalized feedback in middle school mathematics.

ABSTRACT

Collaborative physical manipulation tasks are widely used in STEM education to develop spatial reasoning and collaborative problem-solving. AI tutoring systems for these settings remain limited because they cannot reliably perceive student actions or evaluate in 3D whether those actions are spatially correct. This study investigates how Vision-Language Models (VLMs) can serve as perception and judgment modules in AI tutoring systems for physical block construction. Preliminary work has revealed a fundamental dissociation in current VLMs: they can identify what a student did but cannot evaluate whether it is spatially correct. Our proposed work extends this foundation toward a full AI tutoring pipeline that integrates multimodal signals and is validated through a learning outcomes study.

Keywords

vision-language models, AI tutoring, spatial reasoning, STEM education, collaborative learning

1. INTRODUCTION

This dissertation investigates the use of Vision-Language Models (VLMs) as perception and judgment modules in AI tutoring systems for collaborative physical STEM tasks. The central premise is that effective tutoring in such tasks requires automated systems that can both interpret a learner's actions on shared physical artifacts and evaluate whether those actions move the task toward its goal. Preliminary work indicates that current VLMs can identify what a student did but struggle to evaluate whether it is spatially correct, exposing a fundamental capability gap between perception and judgment. The remainder of this paper details the open problem and research challenges, the theoretical framing of the work, preliminary findings, the proposed research plan, and the expected contributions of the dissertation.

2. PROBLEM STATEMENT AND RESEARCH CHALLENGES

Changsoo Jung, and Nathaniel Blanchard. Toward Vision-Language Models as AI Tutors in Physical STEM Manipulation. In Anthony Botelho, Maria Mercedes T. Rodrigo, Adish Singla, Hiroaki Ogata, Hyojeong So, and Young Hoan Cho (eds.) Collaborative physical manipulation is a cornerstone of STEM education because it develops spatial reasoning and procedural problem-solving [4, 10]. When students build a structure together, a tutor must monitor what is being built, detect deviations from the goal, and deliver corrective feedback in real time. Existing intelligent tutoring systems have focused on language-based feedback [7, 9] and symbolic domain reasoning [11]. These approaches do not transfer to physical manipulation where collaborative group dynamics directly shape how students perform actions on shared artifacts. Recent VLMs are a natural candidate for this role given their ability to process images and language jointly, but several challenges remain before VLMs can be reliably applied as AI tutors in classroom environments.

Visual complexity. Real manipulation sessions involve hands occluding blocks, inconsistent lighting, and camera perspectives that compress depth. Unlike clean rendered scenes used in prior spatial reasoning benchmarks [5, 6], a VLM processing a real video frame must reason about a noisy and partially observable 3D scene.

Incremental state change. A construction task unfolds one block at a time over 20 to 40 minutes. An AI tutor must detect a single block addition, removal, or repositioning against a growing background structure. Detecting absence (a block that was removed) is especially difficult because it requires comparing two states at a location that now appears empty.

Spatial correctness judgment. Identifying what a student did is not the same as evaluating whether it is correct. A tutor must compare the student's result against a goal configuration and determine whether the spatial relationship between blocks matches the target. This requires a form of 3D reasoning that goes beyond object recognition.

Multimodal collaboration context. In multi-party manipulation sessions, directors give spoken instructions to guide the builder [12]. An AI tutor that can ground these instructions spatially could use them to better interpret ambiguous student actions. It is unclear how much this conversational context helps VLM judgment.

These challenges together define the open problem that our study addresses: *can VLMs be made reliable enough to serve as the perception and judgment backbone of an AI tutoring system in a real physical manipulation task, and if not, what is missing?*

3. THEORETICAL FRAMING

In this study, we explore two complementary frameworks. The *model-tracing* paradigm from intelligent tutoring systems [11] holds that an effective tutor must maintain a model of the student's current state and compare it against a target. In a physical manipulation task, this means tracking a 3D block configuration and detecting deviations from a goal structure at each step. We also explore on *grounded language understanding* [2] which requires that language and vision be jointly anchored in physical space. Together, these frameworks motivate our central research question: can VLMs acquire sufficient 3D spatial grounding to support accurate tutoring feedback in physical STEM lab experiments?

4. PRELIMINARY STUDY

As the first phase of the study, we designed and ran an experiment to evaluate whether current VLMs can judge student manipulations in a physical construction task. As illustrated in Figure 1, each case provides four images: a block reference sheet, an initial state, a builder result, and a goal state. Models must identify what manipulation occurred and judge whether the builder's result matches the goal. We evaluated four frontier VLMs on 421 cases drawn from 19 real sessions [12] spanning place, move, and delete actions.

The central finding is a fundamental dissociation. Open-weight 7-8B models correctly identify what manipulation a student performed in up to 93.8% of cases when given structured state contexts. However, their judgment of whether it achieves the spatial goal remains at chance even with the same context. Proprietary frontier models (GPT-5.2 [8], Claude Sonnet 4.6 [1], Gemini 3 Flash [3]) achieve 80-93% judgment accuracy. This result shows that *knowing what happened* and *evaluating whether it is correct* are distinct capabilities in current VLMs and that the second does not follow from the first. This is the core problem we aim to resolve in the proposed studies.

5. PROPOSED RESEARCH

Study 2: Fine-Grained Spatial Error Analysis. The study 1 (Section 4) measures correctness judgment as a binary outcome. Our next step is to decompose errors into fine-grained spatial error types including position offset, stacking level error, and shape confusion. This will identify precisely where VLM spatial reasoning breaks down and inform what targeted representational support is needed for each error type.

Study 3: Multimodal Context Integration. The underlying dataset [12] contains synchronized speech and gesture annotations alongside 3D structure states. Director instructions such as "put the red block to the left of the blue one" provide explicit spatial context that may help a VLM resolve ambiguous context. We will investigate whether integrating transcribed speech and gesture improves judgment accuracy and at what cost in system complexity. This experiment extends our study to multimodal learning analytics.

Study 4: AI Tutor Prototype and Learning Outcomes. The final phase will integrate findings from Studies 1-3 into an AI tutor prototype and evaluate it in a controlled user study. Participants will complete a block construction task with or without AI tutor correctness feedback. The primary outcome is task accuracy, and the secondary measure is spatial reasoning transfer assessed through a post-task evaluation. This study will provide the ecological validity and learning science evidence.

6. EXPECTED CONTRIBUTIONS

Our current study and future research will produce four contributions to the AI and education communities. First, a benchmark for evaluating VLMs as AI tutors in real collaborative physical manipulations with reconstructable 3D ground-truth annotations. Second, empirical evidence that action identification and spatial correctness judgment are distinct VLM capabilities with clear implications for tutoring system design. Third, design guidelines for representing 3D spatial information to VLMs covering input modality and multimodal context integration. Fourth, a controlled study connecting VLM-based tutoring feedback to student learning outcomes in a physical construction task. Taken together, these contributions bridge the gap between VLM capability evaluation and practical AI tutoring design in physical STEM learning environments.

7. CONCLUSION

Physical STEM manipulation is a rich and underexplored setting for AI tutoring research at the intersection of computer vision and learning sciences. This study addresses a concrete open problem: current VLMs can recognize student actions but cannot reliably evaluate whether those actions are spatially correct. Bridging this gap requires better spatial reasoning models and a clearer understanding of what representational support AI tutors need in physical environments. Addressing this gap will advance both the theoretical understanding of VLM spatial reasoning and the practical development of AI tutoring systems for education.

ABSTRACT

This doctoral research investigates the interplay between cognition, affect and metacognition (CAM) in students' engagement with machine learning (ML) tasks in computer-based learning environments. While prior work has examined these CAM processes, limited research has explored how they dynamically interact during complex, data-driven problem-solving. To address this gap, this work proposes the design and development of a tutoring system (ML-Tutor) to teach Machine Learning. This system captures learners' interactions and identifies the affective and metacognitive processes while learning. The research conceptualizes metacognition as embedded within the learning activity and operationalizes it through planning, monitoring, and control processes. A preliminary paper-and-pencil study has informed the design of tasks, prompts, and data collection strategies, demonstrating the feasibility of eliciting multimodal traces of learner activity. This work is ongoing, with current efforts focused on developing the CBLE, refining the analytical framework, and identifying suitable units of analysis for studying temporally unfolding learning processes. Feedback is sought on the conceptual framing, operationalization of metacognition, and methodological approach for analyzing multimodal data.

Affective Computing, Cognitive Processes, Metacognition, Multimodal Learning Analytics, Intelligent Tutoring Systems, Computer-based Learning Environment, Personalization

1. INTRODUCTION

Student engagement is widely recognized as a core component of learning outcomes, particularly in complex, open-ended domains that require sustained effort and self regulation. Some perspectives conceptualize engagement as a multidimensional construct encompassing behavioral, cognitive, and affective components, each contributing uniquely to learning processes ([12, 5, 13]). In recent years, this view has been extended to emphasize the dynamic and situated nature of engagement, where learners' involvement fluctuates over time in response to task demands, contextual factors, and internal states ([20]). This shift toward process-oriented understandings of engagement has become especially relevant in computer-based learning environments, where data enables the study of engagement as it unfolds in real time [2].

Affective Engagement

Affective engagement [19] has emerged as a critical dimension of learning, particularly in computer-based learning environments where learners interact with complex, open-ended tasks. Affective states are not merely byproducts of learning but play a constitutive role in influencing attention, persistence, and strategy use [7]. As such, understanding affective engagement is essential for designing learning environments that can support productive learning trajectories. With the integration of machine learning techniques, [17] detecting affect is possible in more authentic environments. Within the context of educational data mining, affect detection has relied on multimodal learning analytics, enabling richer representations of learners' experiences across cognitive and behavioral dimensions [16]. Current affective computing systems largely treat affect as an observable signal to be detected and responded to, with limited consideration of its interaction with cognitive processes during problem solving [17].

Affect, Cognition and Metacognition

The relationship between affect and cognition is central to understanding self-regulated learning [6]. Efklides' Metacognitive and Affective Model of Self-Regulated Learning [8] (MASRL) conceptualizes this interaction by linking cognitive processing, metacognitive monitoring, and affective experiences such as effort, difficulty, and confidence. Within this framework, affect actively shapes learners' judgments, strategy use, and regulation during task engagement. Recent work has further emphasized the importance of capturing these processes through fine-grained, multimodal data,

https://doi.org/10.5281/zenodo.21039859

demonstrating that understanding self-regulated learning requires integrating trace data, self-reports, observable interaction data [11, 9, 10]. There also is a dynamic and temporal nature of affect and metacognitive processes during learning. Studies have shown that learners' emotional states evolve over time and are closely tied to regulation and task performance [15]. However, there is limited research that integrates cognition, metacognition, and affect to provide a holistic understanding of learning processes. One key challenge lies in the multimodal nature of data collection. Affective states are often captured using modalities such as facial expressions, while cognitive and metacognitive processes are typically inferred from interaction data such as clickstreams. Integrating these heterogeneous data sources remains complex.

> Addressing the challenge of integrating the multimodalities can enable a more comprehensive modeling of learner behavior. Such integrated models have the potential to better capture the dynamics of learning and support the design of more effective, personalized scaffolding strategies in computer-based learning environments.

2. OUR WORK

Our work is situated in the context of machine learning (ML) education for school students. The focus is on developing a foundational understanding of core ML concepts such as classification, features, and similarity-based reasoning through accessible, real-world analogies and interactive activities. The learning tasks are designed to progressively move from intuitive understanding to structured reasoning. For instance, students engage with classification problems using everyday categories (e.g., fruit, objects) before transitioning to simplified representations of algorithms such as K-Nearest Neighbors (KNN). These tasks are intentionally designed to surface cognitive challenges and uncertainty, creating opportunities to observe how learners respond to difficulty in emerging domains such as ML.

The following research goals (RG's) were formulated:

1. To investigate how pedagogical approaches for teaching classification, feature identification, and similarity-based reasoning can be translated into a CBLE.

2. To design and develop a CBLE that embeds opportunities for eliciting and capturing learners' cognitive, metacognitive, and affective processes during task engagement.

Paper-Pencil Based Intervention

A preliminary paper-and-pencil study was conducted to study the feasibility of creating a CBLE aligning with RG 2. The study involved school students in the age group of 11 - 14, engaging with introductory machine learning (ML) concepts through structured activities focused on classification and similarity-based reasoning.

Pedagogical Design and Methodology

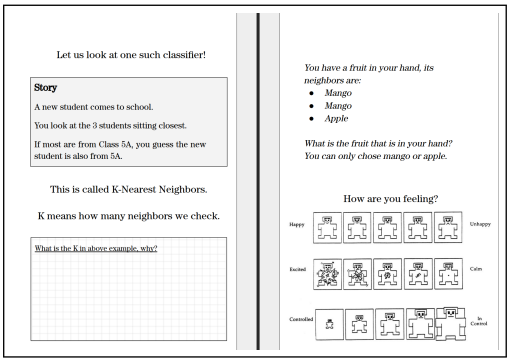

Figure 1: Excerpts from Paper-and-Pencil Intervention

The instructional content was adapted from the CBSE Artificial Intelligence curriculum for grades 6-8, ensuring alignment with age-appropriate learning objectives and prior exposure. Interactive tools such as Teachable Machine [4] were incorporated to enable students to train and test simple models, making abstract processes visible and manipulable. Students then engaged in structured activities like solving classification problems using tabular patient data, requiring them to identify relevant features, compare instances, and make decisions using nearest-neighbor logic. These activities were followed with reflective prompts (e.g., "How are you feeling?") and self-report checklists in the end to encourage monitoring of effort, difficulty, and persistence.

The affective self-report items were adapted from established instruments, the Self-Assessment Manikin (SAM Manikin) and Semantic Differential Scales [3], which have been widely used to capture affective responses in learners of comparable age groups (11 to 14 years). The study was conducted with eight ($N = 8$) participants aged 11 to 14. This design intentionally integrates cognitive engagement with opportunities for metacognitive reflection and affective expression, while also serving as a preliminary exploration of how such task structures and measures may be adapted for implementation within a computer-based learning environment.

Data Collection Strategy

Prior to data collection, formal ethics approval was obtained from the Institute's Ethics and Review Board. Informed consent was obtained from guardians, and assent was obtained from participating students. A multi-source data collection approach was adopted to capture learners' cognitive and affective experiences during task engagement. Data sources included students' responses to structured worksheets (Ref. 1) and embedded self-report measures capturing affective states such as effort, difficulty, and persistence. The instructional material was organized into discrete activities, with affective self-reports using the Self-Assessment Manikin (SAM) [3] administered at the end of each activity to capture affect at multiple points during the learning process 3 In addition to self-reports, video recordings of participants were collected to enable analysis of behavioral and physiological signals. These recordings allow for the extraction of heart rate using remote photoplethysmography (rPPG), a non-contact method for estimating physiological signals from facial videos [21, 18, 1]. To support temporal align-

Figure 2: Student Participant

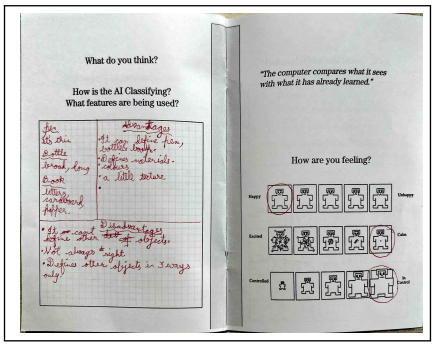

Figure 3: Student Work

ment, the teacher maintained timestamps corresponding to each activity, enabling synchronization of video, self-report, and task data. This multimodal and temporally structured design provides a foundation for examining how affective states, cognitive processes, and physiological indicators co-occur during different phases of task engagement.

Preliminary Observations

While no formal analysis has been conducted, the collected multimodal data provides an initial basis for exploring relationships between cognitive processes, affective experiences, and physiological indicators such as heart rate (rPPG), informing the design of a subsequent computer-based learning environment.

3. CBLE AND EMBEDDED METACOGNITION

The next phase of our research involves the design of an adaptive computer-based learning environment (CBLE) that embeds metacognitive processes within task interaction. Rather than treating metacognition as an external construct measured through post-hoc reports or think-aloud protocols, this work conceptualizes metacognition as an activity that is enacted during learning.

In this work, metacognition is operationalized through three core processes: planning, monitoring, and control [14]. The CBLE will incorporate explicit support for planning by prompting learners to articulate their approach before attempting a task. For example, *learners may be asked to identify which features are relevant for a classification problem or to select a strategy for solving it.* These prompts are designed to provide observable indicators of how learners prepare to engage with machine learning tasks. Such interactions allow planning to be captured as part of the learning process rather than inferred retrospectively. Monitoring processes will be embedded through periodic prompts and checkpoints during task engagement. *These include self-reports of perceived difficulty, effort, and confidence, as well as affective indicators captured through instruments such as the Self-Assessment Manikin. Artifacts for monitoring such as an interactive clock and progress bar will also be available.* By integrating these prompts within task flow, the system captures learners' moment-to-moment awareness of their cognitive and affective states. Control processes will be inferred from learners' interactions with the system, including actions such as *revisiting problems, modifying responses, switching strategies, and persisting after incorrect attempts.* These behaviors provide observable evidence of how learners regulate their learning in response to perceived difficulty or feedback. By capturing these actions alongside planning and monitoring data, the system enables the examination of how metacognitive regulation unfolds during task engagement.

These processes will be integrated within the CBLE consisting of a domain module, a pedagogical module, and a learner module. The domain module will structure machine learning tasks such as classification and, in future iterations, clustering. The pedagogical module will orchestrate prompts and scaffolds that elicit planning, monitoring, and control. Content will be in the form of text, videos, and interactive animations. The assessment will include MCQ's, MSQ's and descriptive questions. The learner module will capture multimodal data, including task performance, self-reports, and physiological signals, enabling the construction of temporally aligned traces of learner activity. Together, this design provides a foundation for studying how metacognitive processes are enacted and how they relate to cognitive and affective dynamics during learning.

4. FEEDBACK SOUGHT

a. Theoretical–Operational Alignment: The adequacy of the proposed conceptualization of affect, cognition, and metacognition, particularly the alignment between the MASRL inspired cognitive–affective loops and their operationalization through multimodal indicators. Whether the mapping from latent constructs (e.g., perceived difficulty, confidence, regulatory control) to observable features is sufficiently well-specified and theoretically defensible.
b. Unit of Analysis and Temporal Segmentation: The validity and analytical utility of defining these affecto-metacognitive episodes as the primary unit of analysis in computer-based learning environments, including the proposed criteria for segmenting continuous interaction data into episodes and the implications of segmentation choices for modeling temporal dynamics and cognitive–affective coupling.

5. CONCLUSION

This work outlines a research trajectory for studying the dynamic interplay between affect, cognition, and metacog-

nition in ML learning environments through the design of an adaptive tutoring system. The preliminary study informs this direction, with future work focusing on refining the analytical framework and leveraging multimodal data from CBLEs to examine learning processes at a finer temporal level.

When and How Does LLM Support Help Learning? Toward Data-Driven Design Principles for AI-Enhanced Educational Interfaces

Eason Chen
Carnegie Mellon University
eason.tw.chen@gmail.com

ABSTRACT

Large language models are rapidly deployed in educational systems, yet fundamental questions remain about when LLM support helps learning and when it may hinder it. This dissertation develops design principles for LLM-enhanced educational interfaces through three studies: (1) an experiment showing that expertise paradoxically reduces AI collaboration effectiveness in educational decision-making; (2) a classroom deployment revealing that conversational chatbot usage is negatively associated with exam performance while structured proof-review is not; and (3) a controlled experiment demonstrating that open-ended self-explanation with LLM feedback significantly enhances transfer in calculus ($p = .030$) while requiring $3.5\times$ fewer practice problems. Drawing on learning analytics and educational data mining perspectives, this work contributes methods for automated assessment of student reasoning ($\kappa = 0.78$ vs. human consensus), behavioral pattern detection from interaction logs, and adaptive feedback design informed by data-driven student models.

Keywords

Large language models, Self-explanation, Automated assessment, Learning analytics, Learner behavior modeling, Human-AI collaboration, Educational data mining

1. PROBLEM AND MOTIVATION

The integration of large language models into education promises scalable, personalized support that was previously possible only through human tutoring or expensive rule-based systems [9]. However, emerging evidence suggests that the *form* of LLM support matters as much as its availability. Unconstrained conversational AI can reduce student-generated reasoning and encourage answer outsourcing [15], while structured interfaces that anchor feedback in student work may better preserve productive struggle [1]. Yet we lack a systematic understanding of *which* design choices matter and *why*.

Self-explanation, the process of articulating the reasoning behind a solution, is one of the most robust learning strategies in educational research [3, 12]. However, it faces longstanding practical barriers: it is time-costly [4], explanation quality varies widely [2], and benefits may disappear when learning time is equated with additional practice [10]. LLMs could provide scalable feedback on student-generated explanations, but whether this preserves the generative processing that makes self-explanation effective remains unclear.

These challenges point to a fundamental gap: while LLMs are being widely adopted in education, we lack principled design guidelines grounded in empirical evidence about which forms of AI support enhance learning and which undermine it. My dissertation addresses this gap through the following research question:

How can LLM-supported self-explanation be designed to maximize learning transfer, and what design principles govern the effectiveness of AI feedback on student reasoning?[1]

2. THEORETICAL FRAMING

I draw on three complementary perspectives.

Self-explanation theory establishes that articulating reasoning promotes learning by helping learners identify gaps and integrate new knowledge [3]. Decades of work in intelligent tutoring systems has shown that prompting students to explain solution steps improves learning, particularly when combined with tutorial dialogue that ensures explanation quality [1, 2]. The open question is whether LLM feedback preserves these generative benefits or short-circuits them.

The ICAP framework [5] predicts that learning outcomes improve as engagement moves from passive to active to constructive to interactive. Self-explanation is constructive; when LLM feedback responds adaptively to student explanations, the interaction may approach the interactive level, where each partner's contribution triggers further knowledge-building. This predicts that open-ended self-explanation with adaptive AI feedback should outperform menu-based selection.

The assistance dilemma [6] and the Knowledge-Learning-Instruction (KLI) framework [7] provide a principled basis for understanding when instructional support helps versus hin-

[1]To preserve double-blind review, we do not cite the author's own publications in this submission. Full citations will be included in the camera-ready version.

ders. The assistance dilemma captures the tension between providing information (reducing errors but potentially reducing learning) and withholding it (increasing productive struggle). The KLI framework specifies that optimal instruction depends on the type of knowledge: sense-making knowledge benefits from constructive activities such as self-explanation, while routine knowledge benefits from practice [8]. In AI-assisted contexts, this manifests as over-reliance (answer outsourcing) versus under-reliance (dismissing valuable feedback) [14]. Interface design and learner characteristics both moderate these patterns [13, 11].

Together, these predict that effective LLM-supported self-explanation requires interfaces that promote generative processing before feedback, provide quality-ensuring feedback without bypassing reasoning, and calibrate support to the type of knowledge and learner characteristics [8].

3. RESEARCH PROGRESS

My research has progressed from understanding how humans interact with AI in educational contexts (Study 1) to examining how LLM interface design shapes learning outcomes in classrooms (Study 2) to directly testing LLM-supported self-explanation as a mechanism for transfer (Study 3). Each study builds on insights from the previous one, progressively narrowing from broad human-AI interaction patterns to specific design principles for self-explanation feedback.

3.1 Study 1: Expertise and AI Reliance in Educational Decision-Making (Published)

Motivation. Before designing LLM tools for learners, I wanted to understand how people use AI recommendations in educational contexts and how expertise moderates reliance. If we cannot predict who benefits from AI assistance, we cannot design effectively for diverse learners.

Method. A within-subjects study ($N = 95$) examined how experienced tutors (experts) and non-tutors (novices) evaluated tutor-praise responses under three AI-assisted conditions: no AI, AI with textual reasoning explanations, and AI with inline highlighting. The task involved judging the pedagogical appropriateness of tutor praise for student work, requiring subject-matter expertise. I decomposed errors into over-reliance (accepting incorrect AI recommendations) and under-reliance (rejecting correct AI advice), treating these as distinct behavioral indicators rather than collapsing them into a single accuracy metric.

Results. AI assistance significantly improved accuracy over unassisted performance ($p = .009$), but human-AI collaboration consistently underperformed the AI-only baseline (88% accuracy), quantifying the "cost of human oversight." A paradox of expertise emerged: novices outperformed experts when AI was present ($p = .021$) because they followed AI suggestions more closely, while experts frequently overrode correct advice. Textual reasoning reduced under-reliance when AI was correct ($p < .05$) but increased over-reliance when AI was wrong, revealing a fundamental trade-off in explanation design. A repeated-measures ANOVA on time cost showed significant main effects for both highlighting ($p < .001$) and reasoning ($p < .001$), with a significant interaction ($p = .001$): users substituted between explanation types rather than simply adding reading time.

Implications. Expertise moderates AI support effectiveness, and explanation design involves fundamental trade-offs between over-reliance and under-reliance. Through the lens of the KLI framework [7], the expertise paradox can be understood as a knowledge-type mismatch: experts' deep domain knowledge leads them to override AI on the basis of sense-making processes, even when the AI's pattern-matching is more accurate for this specific task. These insights motivated me to examine how interface *constraints*, not just explanations, shape the effectiveness of LLM support for learning.

This study demonstrates a key methodology for learning analytics: decomposing aggregate accuracy into process-level indicators (over-reliance, under-reliance, time cost) that reveal the mechanisms behind human-AI interaction effects. This contrasts with prior work that treats AI assistance as a binary treatment and overlooks the quality of human-AI coordination.

3.2 Study 2: Conversational vs. Structured LLM Support in a Course (Under Review)

Motivation. Study 1 showed that interface design affects AI reliance in a controlled task. Study 2 tests whether these dynamics generalize to authentic classroom settings with real learning goals.

Method. We deployed an LLM-powered tool in an undergraduate discrete mathematics course ($N = 148$) using a staggered-access design. The tool integrated two LLM-powered components: a chatbot for conversational math support and a proof-review tool that provides structured, localized feedback on students' written proof attempts. The proof-review tool requires students to first produce their own proof before receiving feedback, while the chatbot allows open-ended conversation. We analyzed adoption patterns, outcome associations, and mediation pathways using log data combined with course performance records.

Results. Earlier access improved homework scores ($B = 2.71$, $p = .026$) but not exam scores. After controlling for self-efficacy and prior performance, chatbot usage negatively predicted exam performance ($B = -0.030$, $p = .014$), while proof-review showed no such association ($p = .480$). To understand this divergence, we coded chatbot transcripts for answer-seeking behaviors (directly requesting solutions rather than conceptual explanations). Students classified as answer-seekers scored significantly lower ($d = 0.55$), and a serial mediation model revealed that chatbot usage partially mediated the self-efficacy $\rightarrow$ exam pathway.

Implications. The proof-review tool, which requires students to generate their own work first (analogous to self-explanation), showed no negative association, while the open-ended chatbot did. This motivated Study 3: if anchoring LLM feedback in student-generated reasoning is key, then explicitly scaffolding self-explanation with LLM feedback should enhance learning. However, this study is observational; usage-outcome associations may reflect selection effects (struggling students may use the chatbot more). A

controlled experiment was needed to test the causal mechanism.

This study exemplifies learning analytics methodology: mining interaction logs to discover behavioral patterns (answer-seeking) and testing predictive models (regression, mediation) for learning outcomes. The answer-seeking classifier represents a potentially deployable tool for real-time intervention in AI-assisted learning environments.

3.3 Study 3: LLM-Supported Self-Explanation in Calculus (Under Review, Central to Thesis)

Motivation. Studies 1 and 2 converged on the hypothesis that LLM interfaces promoting generative processing should yield better learning outcomes. Study 3 directly tests this through a controlled experiment.

Method. A between-subjects experiment ($N = 92$) compared three conditions in a calculus learning environment: no self-explanation (control, $n = 29$), menu-based self-explanation ($n = 35$), and open-ended self-explanation with LLM feedback ($n = 28$). All participants had a fixed 60-minute practice session. Transfer was measured via "Not Enough Information" (NEI) items requiring metacognitive judgment about whether a problem provides sufficient information. Participants were recruited via Prolific and screened for algebra proficiency without advanced calculus background.

The automated evaluation pipeline scored student explanations against a four-level rubric (0, 0.3, 0.7, 1.0) capturing completeness and conceptual accuracy. Two human graders achieved $\kappa = 0.70$ (quadratic-weighted); agreement between the LLM and human consensus was $\kappa = 0.78$ (substantial). The system provided color-coded quality indicators (red/yellow/green) after each attempt, with corrective explanations after two consecutive low-quality responses.

Results. The open-ended condition significantly outperformed control on NEI transfer questions ($\beta = +11.9$ percentage points, $p = .030$, $d = 0.44$; adjusted $R^2 = .204$), while completing 3.5× fewer practice problems (16.9 vs. 58.9) with comparable overall learning gains (+9.3% vs. +9.4%). Menu-based self-explanation did not differ from control ($p = .343$). This directly addresses the concern that self-explanation benefits disappear when learning time is equated [10].

Notably, open-ended participants completed 3.5× fewer problems yet achieved comparable learning gains, suggesting that the time spent explaining was at least as productive as additional practice. They also spent more time on the post-test (20.6 vs. 14.9 minutes, $p \approx .09$), writing more detailed explanations, a behavioral indicator that the intervention shifted their problem-solving approach toward more generative engagement. For NEI multiple-choice items (identifying insufficient information without requiring explanation), the open-ended condition showed a non-significant advantage ($\beta = +9.3\%$, $p = .183$, $d = 0.26$), suggesting that the self-explanation effect is strongest when assessed through explanation quality rather than answer accuracy alone.

Open questions. The sample was not drawn from a classroom. The transfer effect was specific to NEI items; whether it extends to other transfer forms is unknown. The feedback design was fixed; which components are essential has not been isolated.

This study makes a computational contribution to educational data mining: an LLM-based automated assessment pipeline achieving substantial inter-rater reliability with human graders, enabling scalable feedback provision and data collection. This pipeline could be applied to other domains requiring assessment of open-ended student reasoning.

4. PROPOSED THESIS DIRECTION

Study 3's finding that LLM-supported open-ended self-explanation enhances transfer forms the central contribution of my thesis. The finding that open-ended self-explanation with LLM feedback enhances transfer while requiring dramatically fewer practice problems opens several questions: which feedback components are responsible, whether fixed-format feedback can be improved through personalization, and whether these effects hold in authentic classrooms. My planned work addresses these through three directions:

Feedback mechanism decomposition. Study 3 bundles rubric-based scoring, color-coded indicators, and corrective explanations into a single treatment. Which components drive the transfer effect? I plan factorial experiments that systematically vary feedback type (score only vs. score + hint vs. full explanation) and feedback timing (immediate vs. delayed) to isolate causal effects. The automated evaluation pipeline from Study 3 provides the infrastructure to maintain consistency across conditions while scaling to larger samples. This addresses a gap in the self-explanation literature, where feedback designs are typically studied as monolithic treatments rather than decomposed into their constituent mechanisms.

Adaptive feedback intensity. A recurring pattern across my studies is that many comparisons yielded null effects: explanation styles did not improve accuracy in Study 1, proof-review showed no positive association in Study 2, and menu-based self-explanation did not differ from control in Study 3. One interpretation is that fixed-format support is too rigid: the same feedback may over-assist strong students (reducing productive struggle) while under-assisting weak ones (failing to correct misconceptions). I plan to investigate feedback that adapts to explanation quality in real time: minimal acknowledgment for strong explanations (preserving autonomy), targeted hints for partial ones (scaffolding without giving away the answer), and corrective feedback only after repeated failures (preventing frustration). This directly operationalizes the assistance dilemma [6] through data-driven student models, and the KLI framework [7] provides principled criteria for when sense-making support should be intensified versus withdrawn.

Classroom deployment. Study 3 used Prolific participants in a single session. Validating these effects in an authentic course would strengthen ecological validity and test whether benefits persist over longer periods, including across exam performance. The staggered-access methodology from Study 2 provides a template for quasi-experimental deployment. Longitudinal interaction data would also enable trajectory analysis of explanation quality over time, connecting to the EDM

community's work on early warning systems and detector-based interventions. Building on Study 2's answer-seeking coding, I plan to develop automated classifiers from interaction logs that could trigger just-in-time interventions when students shift toward unproductive usage patterns.

4.1 Research Timeline

My timeline prioritizes the highest-impact extensions first. In the near term (next 6 months), I will conduct the feedback mechanism decomposition experiment, as this directly builds on the existing Study 3 infrastructure and addresses the most pressing open question. Concurrently, I will begin developing the answer-seeking classifier using coded transcripts from Study 2 as training data. In the medium term (6–12 months), I will implement the adaptive feedback system, informed by both the decomposition results and trajectory analysis from Study 3 data. The classroom deployment will follow (12–18 months), integrating the adaptive system into an authentic course using the staggered-access design from Study 2.

5. EXPECTED CONTRIBUTIONS

- **Empirical evidence** that LLM-supported open-ended self-explanation enhances transfer ($p = .030$) with 3.5× fewer problems, directly addressing concerns that self-explanation benefits disappear when learning time is equated with additional practice [10].
- **Automated assessment and behavioral detection** pipelines: an LLM-based explanation evaluator ($\kappa = 0.78$ vs. human consensus) enabling scalable feedback, and an answer-seeking classifier from interaction logs enabling just-in-time interventions. These address key bottlenecks in both self-explanation research and EDM early warning systems.
- **Error decomposition methodology** for human-AI interaction, decomposing outcomes into over-reliance, under-reliance, and time cost as process-level indicators, grounded in the KLI framework's distinction between knowledge types [7]. This provides diagnostic information beyond aggregate accuracy for designers of AI-enhanced educational tools.
- **Design guidelines for LLM integration in education**, synthesizing across all three studies: (1) anchor AI feedback in student-generated work; (2) design for generative processing before assistance; (3) monitor and intervene on unproductive usage patterns; (4) calibrate support intensity to knowledge type, learner characteristics, and explanation quality, operationalizing the assistance dilemma [6] through data-driven student models.

6. FEEDBACK SOUGHT

My dissertation is at the transition between completed empirical work and planned extensions. I would particularly value feedback on:

1. **Thesis scope:** Should I focus narrowly on self-explanation feedback design (decomposing which feedback components drive transfer), or maintain the broader framing that connects interface design, reliance patterns, and self-explanation across all three studies?
2. **Transfer measurement:** My current transfer measure is specific (recognizing insufficient information). What additional measures of deep understanding would strengthen the claim that LLM-supported self-explanation promotes genuine conceptual transfer?
3. **Addressing null effects:** Many comparisons across my studies were non-significant. Is adaptive feedback intensity the most promising direction, or are there other design levers more likely to produce robust learning gains?
4. **Theoretical framing:** Is the ICAP-based argument (that LLM feedback elevates self-explanation from constructive to interactive) well-supported, or are there alternative explanations for the transfer effect that the EDM community would find more compelling?
5. **Ecological validity:** What study designs would most convincingly demonstrate that these effects matter in real classrooms, beyond single-session Prolific experiments?

Assessing Early Literacy at Scale: Format Effects in Unsupervised Digital Assessment

Harriet Crisp

amar.lalwani@eidu.com

ABSTRACT

Assessing foundational literacy at scale in low-resource settings is challenging due to the cost of assessor-led testing. Digital platforms offer a scalable alternative, but the performance of different item formats under unsupervised conditions, particularly for young learners, remains underevidenced.

This paper analyses a large-scale deployment of digital assessments delivered through EIDU's platform-based education programme in pre-primary classrooms in Kenya, comprising multiple-choice questions (MCQs) and very short answer questions (VSAQs). Across 230,000 learners and 1.8 million item responses, MCQs achieved significantly higher completion and scores than VSAQs, with item format explaining 31% of variance in completed-assessment scores. However, clustering incorrect VSAQ responses revealed highly structured patterns of partial knowledge, response-format confusion, and emerging phonics understanding that binary scoring entirely obscures.

Binary correctness scoring of both MCQs and VSAQs showed no significant association with an independent literacy assessment (IDELA; linked sample $n = 384$), but classifying incorrect VSAQ responses by degree of understanding uncovered a significant directional signal, though whether this generalises beyond the small validation sample remains an open question. The results highlight a trade-off between MCQ engagement and the richer learner signal in VSAQ errors, motivating further validation of their diagnostic value.

1. INTRODUCTION & MOTIVATION

It is widely recognised that foundational literacy and numeracy skills are essential predictors of future academic success [6, 22], therefore accurate assessment of these skills is essential. This is of particular importance to learners in low- and middle-income countries (LMICs), who consistently demonstrate substantial gaps in these critical areas. National assessments in a Sub-Saharan African country indicate that 60% of Grade 3 learners fail to achieve minimum proficiency levels in reading [29], compared to less than 10% in high income countries [13].

Many widely used child assessment instruments were developed and normed in high-income settings, raising concerns about contextual fit, feasibility, and interpretability when transferred to low-resource environments [7, 8, 14]. In response, LMIC-focused tools have emerged for early learning measurement, including population- and program-evaluation instruments such as IDELA [18] and MELQO [21], and foundational skill assessments such as the Early Grade Reading Assessment (EGRA) and Early Grade Mathematics Assessment (EGMA) [5, 23]. Both EGRA and EGMA have been widely adopted in low- and middle-income contexts for system diagnosis and program evaluation.

However, because these assessments are typically assessor-led, one-to-one, and time-intensive, they are logistically infeasible at scale, constraining their use for continuous learning measurement [3]. This has motivated the development of technology-mediated assessments, including tablet- and computer-based approaches that automate administration and reduce logistical burden [2, 15, 19].

While self-administered digital assessments such as SA-EGRA and SA-EGMA can align well with enumerator-led tools under supervision [26], evidence suggests that assessment validity depends strongly on task format. Although evidence on whether open-ended formats outperform MCQs is mixed [32], spelling tasks using very short answer questions (VSAQs), which require learners to actively type brief responses (e.g., a letter or short word), have shown stronger alignment with non-digital counterparts than MCQs, despite yielding lower raw scores [25]. This advantage is partly attributable to the ability to capture partial correctness, which carries meaningful signal about emerging literacy skills beyond binary scoring [16, 24]. However, given young children's sensitivity to interaction design [4], it remains unclear whether these diagnostic benefits persist in fully unsupervised deployments—an important requirement for scalable assessment in low-resource contexts.

This uncertainty mirrors findings from a broader assessment literature showing that short-answer formats elicit deeper cognitive processing than MCQs, which primarily measure recognition and are more susceptible to guessing [1, 20]. VSAQs better reflect retrieval processes and reduce cueing bias; experimental evidence from digital platforms shows that fill-in questions can lead to better learning outcomes than MCQs through productive struggle, albeit at the cost of lower raw performance [9, 10, 31]. However, this evidence comes largely from older learners in higher-education settings with stable literacy and test familiarity. Whether VSAQs retain diagnostic value for young learners in unsupervised, low-income digital environments, where more difficult tasks increase the risk of disengagement, remains an open question.

This paper addresses this gap by examining how VSAQs function in a large-scale, unsupervised early-grade digital assessment deployment in low-resource settings. Analysis of item-level constructed responses beyond binary correctness reveals systematic patterns of partial knowledge and response-format confusion, which are aggregated into response-aware attempt-quality features. These features yield the only significant directional association with independent literacy outcomes in a linked validation sample, where binary-scored MCQs and VSAQs do not, though cross-validation was inconclusive at the available sample size. The results characterise a trade-off between the accessibility of MCQs and the diagnostic richness of VSAQs, and motivate further validation of richer scoring approaches for unsupervised early-grade assessment.

2. STUDY CONTEXT AND DEPLOYMENT

The analyses in this paper are drawn from EIDU, a large-scale platform-based education programme deployed in low-resource pre-primary and primary school settings. The platform delivers structured daily literacy and numeracy lesson plans aligned to local curricula through low-cost touchscreen Android phones and is used by teachers during regular classroom instruction. The system operates entirely offline, with content and learner interactions stored locally on the device.

Typically, each class has access to a single device. Teachers use the phone to guide lessons, after which it is shared among learners, who take turns interacting individually with the software to complete digital personalised learning (DPL) games without one-to-one adult supervision. Learners spend approximately five minutes each on literacy and numeracy activities daily, with all interaction data anonymised and collected for analysis. The platform is deployed at scale, reaching over 700,000 learners across multiple low- and middle-income countries in Sub-Saharan Africa; prior large-scale experimental work has shown that this delivery model substantially improves foundational literacy and numeracy outcomes over a one-year period [11].

Within the platform, short assessment units were embedded into learners' individual sessions to measure progress against weekly literacy learning objectives. These assessments were delivered alongside DPL games, rather than as a distinct testing activity. As a result, learners were typically unaware that they were being assessed, and all assessment interactions occurred under the same unsupervised conditions as routine learning activities. This design reduces reactivity and testing effects, a persistent challenge in early childhood assessment, while enabling data collection at scale with minimal disruption to classroom routines.

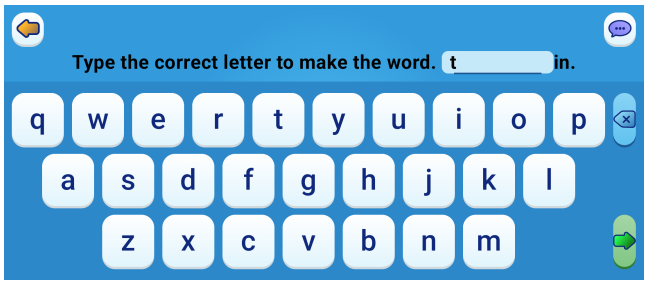

Figure 1: Example of a Blending item (VSAQ).

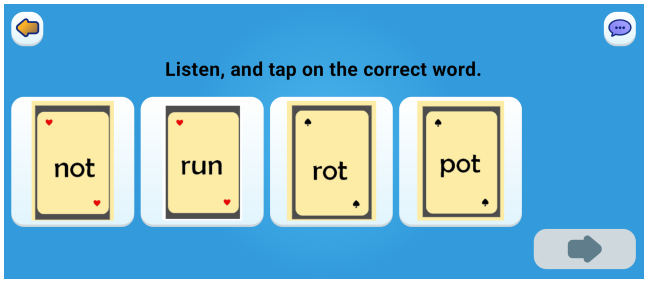

Figure 2: Example of a Word Recognition item (MCQ).

2.1 Assessment Design

A literacy assessment unit was designed for each lesson week during the rollout, aligned to that week's learning objective. Each unit comprised five items and used a single response format: either very short answer input via an on-screen keyboard (VSAQ) or multiple-choice selection (MCQ).

Three item types were used. **Blending** items (Week 1, 3, 6, and 8 assessments) required learners to identify the initial phoneme of a spoken three-letter word by typing the first letter (VSAQ; Figure 1). **Word Spelling** items (Weeks 4 and 5) required learners to type the full three-letter word after hearing the audio prompt (VSAQ). **Word Recognition** items (Weeks 2 and 7) required learners to select the written word matching the audio from four options (MCQ; Figure 2).

2.2 Serving and Interaction Conditions

Assessment units were unlocked once the teacher marked the fifth lesson of the corresponding week as complete, and served to each learner as the first unit in their next DPL session. Learners could exit units at any point, proceeding directly to standard DPL games.

All assessments were completed under unsupervised conditions. Teachers did not receive real-time feedback during assessment attempts, and learners received no guidance beyond the on-screen and audio instructions provided by the software. As a result, assessment outcomes reflect not only learners' underlying knowledge, but also interaction behaviour, including misunderstanding of task requirements, typing errors, and other interface-related effects.

2.3 Study Sample and Data

The assessments were rolled out to Pre-Primary 2 (PP2) learners in Kenya, typically around five years old, over six weeks during the final term of the 2025 school year (September–October). Of approximately 420,000 PP2 learners active on the platform during the roll-out window, around 230,000 learners (55%) were served at least one assessment; the remaining learners were in classes that did not reach the lesson-completion thresholds required to unlock assessments. Across these learners, approximately 1.8 million item responses were collected, averaging 1.6 completed assessments per learner.

In addition to the digital assessment data, assessor-administered IDELA assessments were conducted in October 2025 with a randomly selected sample of PP2 learners across 60 schools in a single programme county. Of the 477 learners assessed, 384 also completed at least one digital assessment and are included in subsequent analyses. Mean IDELA literacy scores were similar for the full sample (63.9%) and the linked subsample (64.3%). IDELA is delivered orally in one-to-one settings and aggregates performance across foundational subtasks including letter–sound knowledge, print awareness, and expressive vocabulary, providing a holistic independent benchmark for early literacy.

3. METHODOLOGY

In the operational system, assessment items were scored using binary correctness, based on whether the learner's response exactly matched the expected answer. For completed assessments, unit-level scores were computed as the average proportion of correct responses. The analysis proceeds in three stages:

1. An initial descriptive analysis of assessment outcomes and raw responses.
2. Item-level analysis and clustering of incorrect VSAQ inputs.
3. Predictive modelling to evaluate how different representations of learner performance align with external outcomes.

The descriptive findings from Stage (1) are reported in the Results section; this section describes the response processing and feature construction steps used in Stages (2) and (3).

3.1 Response Processing

While the operational system scored items as binary correct or incorrect, prior research shows that partially correct constructed responses can contain meaningful learning signal beyond correctness alone [17, 27, 28]. To capture this signal, incorrect VSAQ responses were examined to identify systematic patterns in learner input.

Unique incorrect response strings were grouped using hierarchical agglomerative clustering over character n-gram Term Frequency-Inverse Document Frequency (TF-IDF) representations, with a distance threshold used to induce clusters. Inspection of these clusters revealed recurring structural response forms and their relative frequency in the data. These insights informed the definition of a fixed set of twenty interpretable *response pattern* categories (e.g., partial phoneme matches, character repetitions, reversals, or copying visible text). All incorrect responses were subsequently assigned to one of these categories through manual labelling, with ambiguous cases resolved through author discussion.

Importantly, all response clustering and category assignment was conducted independently of, and prior to, the statistical analyses linking digital features to external outcomes; categories were defined based on interpretation of learner cognition, not optimised for downstream predictive performance.

3.2 Feature Construction

Each granular response pattern category was assigned to one of five ordered *attempt-quality levels*, reflecting increasing degrees of task engagement and correctness:

- **Non-Meaningful Attempt**: Inputs showing no evidence of meaningful item engagement (e.g., *qwerty*).
- **Low-Quality Attempt**: Responses indicating limited engagement with the item but no clear evidence of item-relevant understanding (e.g., entering the letters displayed on the screen).
- **Partially Correct Attempt**: Responses demonstrating partial or emerging understanding of the target concept, but which are incomplete or incorrect (e.g., only writing the first two letters of the word in a Word Spelling assessment).
- **Conceptually Correct Attempt**: Responses that reflect correct conceptual understanding but fail to meet the formatting expected by the interface (e.g. writing the full word in a Blending assessment where only the first letter is required).
- **Fully Correct Attempt**: Responses that satisfy formal correctness under the operational scoring rules.

For each learner, the sum of items in each attempt-quality level was computed and normalised by the total number of items attempted, meaning both complete and incomplete assessments could be included in analysis. These aggregated representations serve as the primary features for evaluating alignment with external learning outcomes.

3.3 Baselines

To assess the added value of response-aware representations, the proposed features were compared against two baselines: correctness-only VSAQ scores (proportion of Fully Correct attempts under binary scoring) and correctness-only MCQ scores.

3.4 Ethical Considerations

This study used anonymised data collected as part of routine platform operations, conducted with the consent and support of participating counties and local stakeholders. Personally identifiable information is encrypted locally on devices, and gatekeeper consent is obtained for all learners.

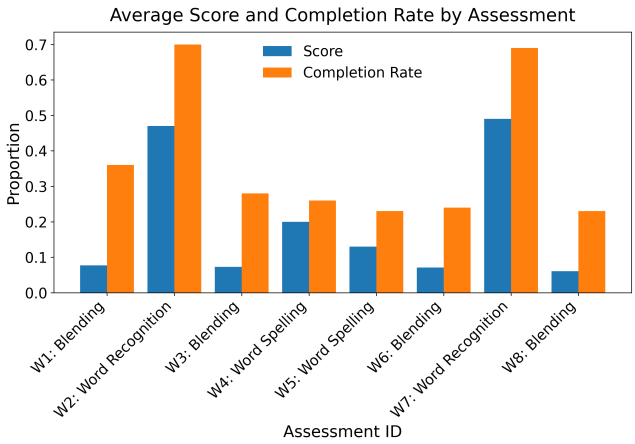

Figure 3: Completion Rate and Score by Assessment ID.

4. RESULTS

4.1 Completion and Performance

Completion rate reflects the proportion of learners who submit responses to all five items in an assessment, while score reflects correctness conditional on completion. As shown in Figure 3, both metrics varied strongly by assessment format. MCQ-based assessments (Weeks 2 and 7) achieved substantially higher completion and scores than VSAQ-based assessments (all other weeks). Assessment format alone explained 31% of the variance in completed-assessment scores ($R^2 = 0.313$), with MCQ assessments yielding scores 38 percentage points higher on average ($p < 0.001$). It should be noted that since both MCQ assessments had four response options, random guessing would yield an expected score of 25%, partly contributing to the higher raw scores observed relative to VSAQs. Format effects were also evident for completion: a logistic regression predicting assessment completion from format alone showed that MCQ assessments were over three times more likely to be completed (odds ratio ≈ 3.1, $p < 0.001$; pseudo-$R^2 = 0.047$).

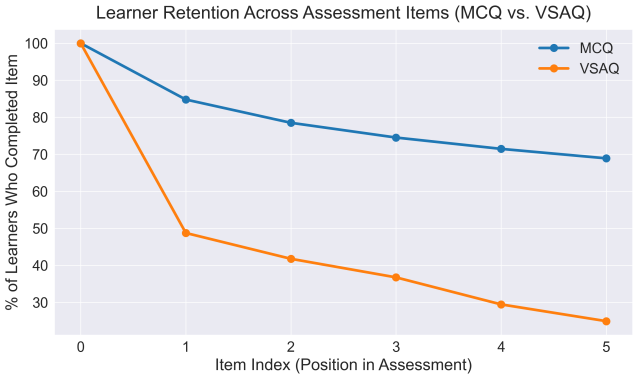

Figure 4: Learner retention across items for MCQ- vs VSAQ-based assessments.

Figure 4 shows the proportion of learners who attempted each item for MCQ vs VSAQ-based assessments, normalised to the introductory screen. All learners shown completed the introductory item, which required only tapping *"Start"* to proceed. As both formats comprised five scored items, differences in dropout rates cannot be attributed to assessment length. Approximately 85% of learners who reached the introduction attempted the first scored MCQ item, compared to only 49% for VSAQs, indicating an immediate response-format barrier rather than gradual disengagement. Among those who attempted the first item, subsequent attrition remained higher for VSAQs (24% drop-off vs. 16% for MCQs). This pattern is consistent with sustained difficulty in responding to typed-input items relative to recognition-based formats.

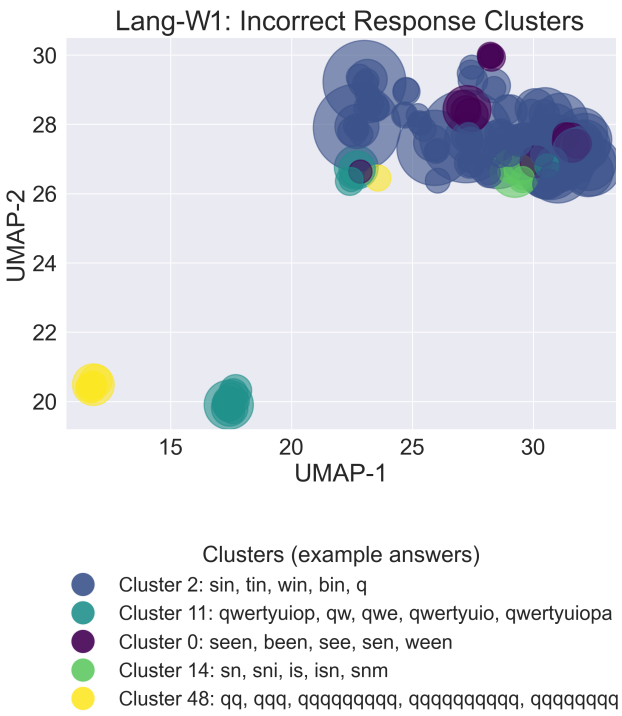

Figure 5: Largest Incorrect Response Clusters for Week 1 Blending assessment.

4.2 Systematic Patterns in Item Responses

Item-level analysis of incorrect VSAQ responses revealed highly structured and interpretable patterns rather than random error.

Figure 5 shows a two-dimensional Uniform Manifold Approximation and Projection (UMAP) visualisation of the five largest clusters of incorrect responses for the Week 1 Blending assessment, in which learners were prompted to enter the initial letter of a spoken three-letter word with the rime *in*. The clustering reveals various recurring response forms, including full word entry, rime substitution, letter reversal, character repetition, and keyboard-swipe inputs. Despite reflecting very different levels of understanding, all are marked as incorrect for failing the formal constraint of providing only the first letter.

Similar response forms were observed consistently across items and weeks, indicating systematic rather than item-

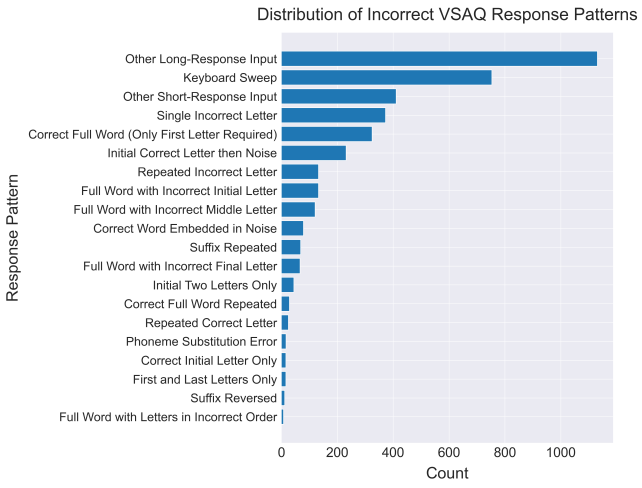

Figure 6: Distribution of response pattern categories across all VSAQ incorrect items.

specific behaviour. Across the four Blending weeks, the most common incorrect response for 90% of items was typing the full word rather than the initial letter, indicating recognition of the target phoneme but misunderstanding of the response requirement. Conversely, in Word Spelling assessments, where the full word was required, a substantial proportion of incorrect responses consisted of only the initial letter. This asymmetry suggests confusion between visually similar task formats that place different demands on learner input. More generally, these response patterns reflect structured partial understanding rather than random error, highlighting signal that binary scoring obscures.

Figure 6 shows the distribution of incorrect VSAQ item responses across the twenty response pattern categories. The three largest categories, accounting for 57% of attempts, reflect disengaged inputs: keyboard sweeps and other unstructured long or short responses. Beyond these, the most frequent patterns indicate partial or misdirected task engagement, such as single incorrect letters, entry of the full word and provision of the correct initial letter followed by unstructured text.

Figure 7 shows the distribution of item responses across the five higher-level attempt-quality categories. While fully correct responses account for only 7% of attempts, a further 22% fall into intermediate categories that reflect partial or conceptual correctness constrained by response format. This structure motivates the use of response-aware representations rather than binary correctness when modelling early learning outcomes.

4.3 Alignment with External Outcomes

To evaluate the extent to which digital assessment signals reflect underlying literacy ability, digital learner representations are compared against assessor-administered IDELA literacy scores, a widely used measure of early literacy skills.

Linear regression models were used to compare three representations of digital learner performance against IDELA literacy scores. In all models, the dependent variable was the

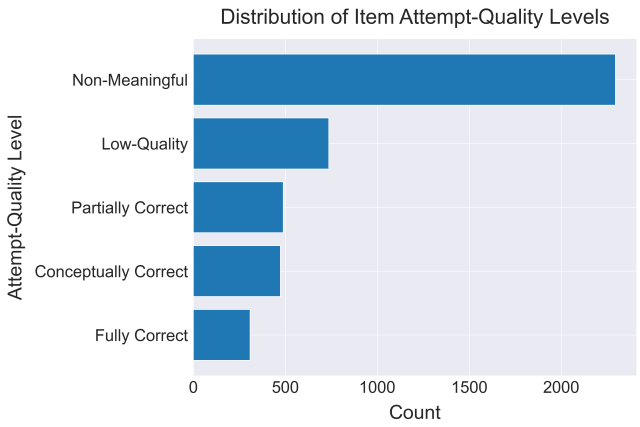

Figure 7: Distribution of item responses across attempt-quality levels.

learner's IDELA literacy score, and predictors were standardised learner-level features derived from digital assessments. The following representations were compared:

1. **MCQ correctness-only**: the proportion of MCQ items answered correctly.
2. **VSAQ correctness-only**: the proportion of VSAQ items answered strictly correctly.
3. **Response-aware VSAQ features**: the distribution of attempt-quality levels across VSAQ items.

Regression coefficients therefore represent the expected percentage point (pp) change in IDELA literacy score associated with a one standard deviation (SD) increase in the corresponding digital assessment feature.

Table 1: Comparison of digital assessment representations for predicting IDELA literacy scores.

Model	R^2	CV R^2	Model p-value
MCQ (correctness)	0.005	-0.064	0.283
VSAQ (correctness)	0.018	-0.062	0.009
VSAQ (response-aware)	0.095	0.008	< 0.001

As shown in Table 1, predictive alignment was weak for both binary-correctness representations: correctness-only VSAQ models explained little variance ($R^2 = 0.018$), while MCQ-only models explained almost none ($R^2 = 0.005$) and were not statistically significant. In contrast, the response-aware VSAQ model achieved higher, though still modest, explanatory power in sample ($R^2 = 0.095$) with monotonic associations with IDELA literacy scores. However, 10-fold cross-validated R^2 was near-zero or negative across all three models, with the response-aware model the only one to retain a positive R^2_{CV} (0.008). With each fold containing only approximately 38 learners, stable out-of-sample estimation is difficult at this sample size [30], and larger-scale external validation is needed.

Despite the correctness-only models explaining little variance in external literacy outcomes, Table 2 shows that cor-

Table 2: Learner-level linear regressions predicting IDELA literacy score: correctness-only models.

Model	Variable	Mean	SD	Coef.	p
MCQ	Intercept	–	–	66.36	< 0.001
	Correct (prop.)	0.43	0.50	1.10	0.283
VSAQ	Intercept	–	–	64.33	< 0.001
	Correct (prop.)	0.07	0.16	2.31	0.009

Table 3: Learner-level linear regression predicting IDELA literacy score: response-aware VSAQ model. (Per-item effects assume five items per assessment, i.e., one item corresponds to 0.2 of the proportion scale)

Attempt Type	Mean	SD	Coef.	p	pp per Item
Intercept	–	–	64.33	0.000	–
Low-Quality	0.17	0.18	-0.00	1.000	ns
Partially Correct	0.12	0.16	2.78	0.001	3.48
Conceptually Correct	0.11	0.17	3.92	0.000	4.61
Fully Correct	0.07	0.16	2.62	0.002	3.28

rectness coefficients were positive in both cases, indicating directional association with higher literacy scores, with a larger effect for VSAQs (2.31 vs. 1.10), though both were weak and, for MCQs, not statistically significant.

In contrast, Table 3 shows that response-aware VSAQ features recover richer signal. In this model, Non-Meaningful attempts serve as the reference category. Partially and conceptually correct attempt-quality features both retain independent predictive power even when controlling for fully correct responses. Conceptually correct attempts show the largest association (3.92pp per SD), exceeding that of fully correct attempts (2.62pp), suggesting that responses reflecting correct understanding but incorrect formatting carry meaningful signal. As noted above, these are in-sample associations and larger-scale validation is needed to establish whether they generalise.

5. DISCUSSION AND CONCLUSIONS

This study examines how pre-primary learners engage with different digital assessment formats in large-scale, unsupervised, low-resource settings, and what this implies for scalable learning measurement. Consistent with prior work, MCQ-based assessments were substantially easier for learners to complete: scores were 38 percentage points higher and completion odds were more than three times those of VSAQ-based assessments. In contrast, VSAQs exhibited sharp early attrition, with around half of learners exiting before attempting the first scored item. This pattern points to an immediate interaction or response-format barrier rather than gradual disengagement. While such barriers are typically mitigated in supervised settings, where an adult ensures task completion, in unsupervised contexts increased task difficulty directly reduces data coverage. This gap may be partially addressed through improved task scaffolding to clarify response expectations.

A central finding of this study is that incorrect VSAQ responses can contain highly structured and interpretable signals. Learners frequently produced responses reflecting partial phonological knowledge, confusion between task formats (e.g., writing the full word when only the initial letter was required, and vice versa), and emerging but incomplete literacy skills. These patterns were consistent across items and weeks, indicating systematic rather than idiosyncratic behaviour. The attempt-quality taxonomy developed here captures a gradient of learner understanding that binary scoring collapses entirely.

These response-aware features yielded the only statistically significant in-sample association with IDELA literacy scores, where correctness-only representations did not. However, cross-validated performance was weak across all models. Low explained variance is common when linking digital process data to external benchmarks in low-income early-childhood settings [12, 33], and in the present study, noise is compounded by fully unsupervised administration on shared classroom devices, a narrow sub-skill focus relative to the holistic IDELA composite [18], and a small single-county validation sample ($n = 384$). The key question for future work is therefore not whether alignment is strong in absolute terms, but whether the directional signal observed here can be confirmed with larger and more diverse validation samples.

Together, the findings suggest that moving beyond binary scoring of constructed responses may provide diagnostic value in unsupervised early-grade digital assessment. MCQs sustain engagement, but VSAQ errors carry structured learner signal that conventional scoring discards. Hybrid designs combining both formats, alongside richer scoring and improved scaffolding to mitigate early attrition, offer a promising direction for scalable learning measurement in these settings.

6. LIMITATIONS AND FUTURE WORK

This study has several limitations. The external validation sample is small ($n = 384$), drawn from a single county, and insufficient to support stable out-of-sample predictive validation. Digital assessment data are observed only for learners in classes that progressed far enough to unlock assessments, introducing potential selection bias, and response pattern categories were assigned through potentially subjective manual labelling. The analyses are limited to PP2 learners and a single language and interface design, limiting generalisability to other age groups or contexts. MCQ and VSAQ formats were confounded with item type (word recognition vs. blending/spelling), limiting causal attribution of observed differences to response format alone.

Future work should prioritise larger-scale external validation with independently sampled learners across multiple regions. Validating the attempt-quality framework across additional grades, subjects, languages, and deployment settings will be essential for establishing its broader applicability. Scalable and automated approaches to response classification should also be explored, alongside examination of how response-aware signals can be incorporated into adaptive instruction or feedback. The sharp initial attrition observed for VSAQs points to the need for improved task scaffolding, such as clearer instructions, worked examples, or tighter input constraints, to reduce response-format confusion while preserving diagnostic value.

ABSTRACT
This study investigates the cognitive and behavioral characteristics of Chinese digital writing by modeling Pinyin-mediated keystroke processes. Prior keystroke research has largely focused on alphabetic languages, where keystrokes map directly onto text, limiting transferability to Chinese input methods that involve phonological entry followed by candidate selection. To address this gap, we propose a Dual-layer Rhythm Model (DLRM) that separates physical keystroke execution from cognitive-level selection and commitment processes. Using fine-grained keystroke logs from 34 graduate students completing both a transcription task and an argumentative writing task, we extracted process features related to input rhythm, candidate-selection latency, pause structure, and revision behavior. Within-subject comparisons showed that argumentative writing produced significantly greater rhythm variability, longer selection latencies, and higher revision rates than transcription, indicating increased cognitive load. Correlation analyses further revealed that cognitive-layer pause indicators, especially within-character pauses and post-commit pauses, were significant negative predictors of argument quality, whereas physical-layer speed measures were not. These findings demonstrate that cognitively grounded timing features derived from Pinyin input provide meaningful indicators of writing proficiency and support the development of process-aware models for Chinese writing assessment and intelligent writing support systems.

Keywords
Chinese writing, keystroke logging, Pinyin input, cognitive load, writing process analytics

1. INTRODUCTION
Writing involves complex cognitive processes such as planning, organizing, expressing ideas, and revising[6]. These processes require the coordinated operation of higher-order functions, including working memory, attentional control, and knowledge retrieval[6, 25]. Therefore, inferring writers' cognitive abilities solely from the final text provides an incomplete and potentially biased view, process-level evidence is also needed[8]. A deeper understanding of the cognitive mechanisms underlying the writing process is essential for strengthening the validity of writing assessment, improving writing instruction, and developing automated, process-sensitive interventions[10].

Traditional process-tracing methods such as think-aloud protocols are limited by verbalization costs, incomplete introspective access, and poor scalability[13, 20].

Keystroke logs provide a window into cognitive processes that are not visible in the final written product [20]. They capture fine-grained behaviors such as typing speed, pauses, revisions, and bursts of text production[7, 20]. Moreover, the high temporal resolution, non-intrusive nature, and ecological validity of keystroke data make it well suited for large-scale studies of writing processes and for developing automated, process-aware writing assessment systems[8, 20].

However, research on keystroke-log analysis for Chinese writing remains far less developed than in English[11]. Chinese writers typically rely on Pinyin input methods as a proxy for text production[34]. Most Chinese input methods involve a two-stage process: writers first enter Pinyin letters that represent the intended Chinese characters, and then identify and select the target character from a list of candidates[21]. This workflow introduces additional cognitive steps, making analytical approaches developed for alphabetic-language keystroke data difficult to transfer to Chinese. Consequently, advancing keystroke-based methods for studying Chinese writing requires process-analytic techniques that explicitly model the Pinyin-mediated input stream[23].

Empirical research on Chinese writing with Pinyin input remains limited. Existing studies have primarily examined how Pinyin input affects lexical processing, while paying less attention to how Pinyin-mediated input unfolds during authentic writing tasks[6]. Systematic analyses that link input-process features to writing quality are especially scarce. Against this backdrop, the present study proposes a method for analyzing keystroke logs of Pinyin-mediated Chinese input, characterizes behavioral features of the input process, and investigates their underlying cognitive mechanisms. We further model the relationship between input processes and writing quality. Specifically, we address the following research questions:

RQ1: What are the key characteristics of Pinyin-mediated Chinese input, and how should these features be interpreted?

RQ2: How does input during writing differ from input during simple typing, and what cognitive activities might these differences reflect?

RQ3: Which input features are associated with writing proficiency, and what are their plausible cognitive interpretations?

2. RELATED WORK
2.1 Chinese Pinyin Keystroke Analysis
Keystroke-log research in English writing has established relatively mature theoretical and methodological foundations[20]. In English, keystroke events map relatively transparently onto the language production process. Accordingly, English keystroke-log studies have focused on physical-level properties of letter input[9], focusing on physical-level properties such as IKI, pause frequency, revision rate, and burst length [7, 20].

However, entering Pinyin letters externalizes only phonological encoding; the intended Chinese characters are not committed to the

text until the writer identifies and selects the target orthographic form from a candidate list (see Figure 1)[16, 26, 28, 38]. This adds a cognitive step from sound-based encoding to character-form selection that does not exist in alphabetic keyboard input.

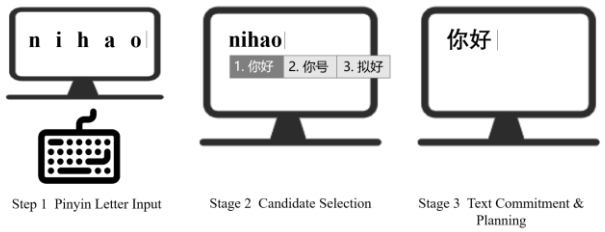

Figure 1. Chinese Pinyin Input Process

Consider intra-word pauses as an example. In Chinese keystroke data, there is no direct counterpart to the English operational definition[16, 29, 30]. Some studies have imported English criteria and defined intra-word pauses as pauses when the cursor is positioned between two Chinese characters within a "word" in the text box[36]. Theoretically, however, such pauses are difficult to interpret as spelling retrieval or orthographic encoding, making the validity of these analyses questionable. More importantly, these definitions ignore pauses at the Pinyin-entry stage and pauses during candidate selection[35].

In Pinyin-mediated input, physical keystrokes represent only the first stage of language production. The cognitive translation from Pinyin to Chinese characters has its own temporal dynamics and cognitive demands[15]. The interval between completing Pinyin entry and confirming a character (i.e., selection latency) is a Pinyin-specific temporal indicator that reflects the cost of orthographic recognition and decision making. Such cognitively meaningful indicators may contain critical information about Chinese writing processes, yet prior Chinese keystroke analyses have not systematically accounted for them[32]. Moreover, relying on cursor position in the text box introduces an additional challenge: accurate Chinese word segmentation, which is itself non-trivial and can propagate error into feature extraction. Together, these issues create substantial technical and theoretical challenges for keystroke-based research on Chinese writing.

More importantly, prior work rarely uses designs that disentangle the cognitive load induced by transcription from the cognitive load of the writing task itself[18, 19]. Keystroke logs reflect an intertwining of input and composition processes: inter-keystroke intervals are shaped by typing proficiency, but they also vary with writers' ongoing planning, formulation, and revision[20, 33]. In Pinyin-mediated Chinese input, transcription itself involves multistage cognitive processing and substantial individual differences. Without controlling for, or directly measuring, the cognitive demands of the input system, it is difficult to estimate the cognitive characteristics of the writing process accurately[14, 37].

2.2 Working-Memory Model of Writing

Baddeley's multicomponent model of working memory provides a useful framework for explaining the cognitive mechanisms involved in writing[3]. The model comprises three subsystems: the phonological loop, the visuospatial sketchpad, and the central executive[4, 5]. These subsystems interact to enable written composition.

Pinyin-mediated input places qualitatively different demands on working memory than handwriting[24]. During phonological encoding, Pinyin input requires writers to activate phonological representations of the intended words and maintain them in the phonological loop[27]. In contrast, during handwriting, many writers rely more on visuospatial memory or directly map orthographic forms to motor actions[17]. During candidate selection, Pinyin input requires maintaining a visual representation of the candidate list in the visuospatial sketchpad while the central executive supports feature comparison and choice decisions. During strategy management, the central executive must monitor the input method's predictions, evaluate the efficiency of the current strategy, and switch strategies when needed[12]. Consequently, especially when the process is not fully automatized, Pinyin input may impose higher working-memory load and reduce the resources available for other components of writing.

Skill acquisition theory posits that complex skills shift from controlled to automatic processing[1, 2, 22] When Pinyin spelling and candidate selection are highly automatized, transcription costs are minimized, freeing cognitive resources for content development[25] . In contrast, non-automatized input competes with composing processes, disrupting idea flow[19, 31]

Building on the cognitive theories reviewed above, we propose the DLRM (Dual-layer Rhythm Model) of Pinyin input as a theoretical framework for analyzing Chinese digital writing processes. The model decomposes Pinyin-mediated input into two relatively independent temporal dimensions: a physical layer and a cognitive layer. The physical layer refers to inter-keystroke intervals between Pinyin letters, which reflect the automatization of Pinyin encoding and the fluency of finger-motor execution. These temporal patterns are primarily shaped by input proficiency; once a sufficient level of skill is reached, Pinyin entry becomes a highly automatized motor program whose rhythm is relatively stable across writing tasks and less sensitive to fluctuations in task-related cognitive load.

In contrast, the cognitive layer captures the interval from completing Pinyin entry to confirming the target Chinese character, as well as intervals between successive character confirmations. These time points mark key cognitive transitions from phonological activation to orthographic retrieval, while also carrying signals of higher-level composing processes such as lexical access, syntactic assembly, and semantic integration. Consequently, cognitive-layer timing is expected to be highly sensitive to writing-task demands. The relationship between the two layers reflects writers' resource allocation strategies: skilled writers can maintain physical-layer fluency while allocating sufficient time at the cognitive layer to support high-quality decisions.

Based on this framework, we propose the following hypotheses:

H1: Compared with a transcription task, an essay-writing task will impose higher cognitive load, reflected in (a) greater variability in physical-layer rhythm, (b) longer cognitive-layer processing time, and (c) more frequent revisions and strategic input behaviors.

H2: Cognitive-layer indicators (e.g., selection latency, inter-character confirmation intervals, and pause patterns during selection) will predict argumentative writing quality more strongly than physical-layer indicators.

3. METHOD

3.1 Participants and Experimental Design

We used a within-subject experimental design to characterize Pinyin-mediated Chinese input behaviors associated with idea

generation under different writing-task conditions. Participants were 39 native Chinese-speaking graduate students, all of whom had extensive experience using Pinyin input methods for computer-based writing. The study was conducted in a controlled, in-person setting. Keystroke data were recorded using the logging module integrated into the CLASS platform.

The experiment included two writing tasks designed to induce different levels of cognitive load during Chinese Pinyin input (see appendix A and B).

The first task was a transcription task, in which participants were asked to accurately copy a provided Chinese philosophical passage within five minutes. The text discussed the nature of logic and knowledge and was approximately 173 characters long. This task served as a low–cognitive-load baseline condition, primarily reflecting transcription and input-rhythm characteristics under minimal idea-generation demands.

The second task was a timed argumentative writing task. Participants were given a structured argument prompt adapted from a standardized analytical writing assessment and were asked to compose a full written response within 30 minutes. The prompt required participants to analyze the assumptions underlying a recommendation and evaluate its logical validity. This task was designed to elicit high-level cognitive activities, including planning, reasoning, and argument construction, under authentic composition conditions.

3.2 Data Collection and Preprocessing

Before feature computation, we cleaned and standardized the raw keystroke logs. We excluded one participant with extremely low task completion and four participants who did not produce valid Pinyin-mediated input, yielding a final analytic sample of 34 participants. We then harmonized potential logging differences caused by input-methods by retaining only events directly related to text production. Finally, we reconstructed each participant's continuous input stream by ordering events chronologically within each task. After cleaning, Task 1 contained 21,975 valid keystroke records and Task 2 contained 99,554 records.

3.3 Modeling Pinyin Input Behaviors

Because Pinyin-mediated Chinese input does not directly produce Chinese characters but proceeds through Pinyin letter entry followed by candidate selection, we explicitly modeled the Pinyin-mediated input process. Using the keystroke logs, we reconstructed each participant's stream of Pinyin letter entry by tracking insertions and deletions at the end of the Pinyin buffer and assigning a timestamp to each letter event. We then computed inter-key intervals (IKIs) at the Pinyin-letter level and extracted summary statistics to characterize input rhythm and its stability. In addition, we quantified deletion behavior as an indicator of online monitoring during transcription.

In Pinyin-mediated input, the commitment of a Chinese character to the final text is treated as a key boundary of text production. End-of-text generation typically reflects the immediate externalization of ideas: writers must concurrently translate concepts into linguistic form, retrieve lexical items, and perform syntactic encoding. Its temporal properties therefore provide a more direct indicator of cognitive load during content generation.

Accordingly, we focused on incremental generation events that increased the text at the end. After each keystroke, if the number of final characters at the end of the text increased relative to the previous event, we labeled the event as an end-of-text generation (i.e., an incremental commit). Events occurring in the middle of the text or involving deletions were excluded from this analysis. For each end-of-text commit, we computed (a) the interval between the final Pinyin-letter keystroke and the appearance of the Chinese character, as an indicator of cognitive effort in candidate recognition and decision making, and (b) the interval between consecutive commits, to capture ideation or planning processes following completion of a production unit.

A data-driven pause threshold of 1,411 ms ($\mu + 1\sigma$ of the pooled inter-event interval distribution, excluding task-unrelated interruptions >10 s) was applied consistently across both tasks.

A key challenge in Pinyin analysis is how to segment Pinyin input in a way that captures individual input habits. To address this, we developed a Pinyin–character alignment model that maps the Pinyin input stream to the final committed Chinese characters(Figure 2). The alignment uses character-commit events as boundaries. For each commit, the model traces backward to retrieve the most recent contiguous sequence of Pinyin letters and treats it as a candidate Pinyin string, which is then enumeratively matched to the committed character(s).

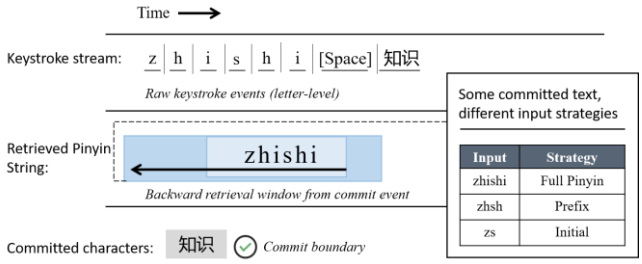

Figure 2. Illustration of the Pinyin–Character Alignment Procedure Based on Commit Boundaries

Based on the selected alignment, we identify and count the use of different Pinyin input strategies (e.g., full Pinyin, initial-letter abbreviation, and prefix-based abbreviations, see Table 1). To control for differences in task duration and text length, strategy usage, pause frequency, and related indicators are normalized by the total number of committed characters, yielding proportion-based measures.

Table 1: Illustration of Pinyin Input Strategies

Strategy Type	Target Characters	Input Letters	Description
Full Pinyin	知识	zhishi	All letters of the full Pinyin spelling for each syllable are entered.
Prefix-based abbreviation	知识	zhsh	A reduced prefix form is entered, keeping multiple leading letters from each syllable.
Initial-letter abbreviation	知识	zs	Only the first letter of each Pinyin syllable is entered.

The alignment model successfully resolved 87.75% of all commit events (alignment coverage rate), yielding a mean of 2.35 committed characters per commit event. The remaining 12.25% of events, in which no valid Pinyin string could be retrieved within the backward-search window or in which the constraint-based filtering could not uniquely resolve the alignment, were excluded from strategy-level analyses but retained for timing-based analyses (e.g.,

inter-key intervals and pause rates), which do not require Pinyin segmentation.

Among successfully aligned commits, the strategy classification yielded the following aggregate distribution: full Pinyin (M = 77.69%), initial-letter abbreviation (M = 12.86%), prefix-based abbreviation (M = 7.83%), and grouped input with backspace correction (M = 1.62%). The last category comprised events in which the Pinyin buffer was interrupted by mid-buffer deletions prior to character commitment; because such sequences could not be unambiguously attributed to a single input strategy, they were excluded from subsequent strategy-level comparisons. No events fell into the residual "other" category (M = 0.00%), indicating that the constraint-based filtering algorithm exhaustively accounted for all strategy types within the aligned portion of the data.

Based on their location in the input stream, we categorized pauses into three types. (1) Within-character pauses are long intervals occurring during Pinyin letter entry and may reflect difficulty in phonological encoding or momentary shifts of attention. (2) Selection pauses are long intervals between completing Pinyin entry and selecting a candidate character, capturing cognitive load associated with orthographic recognition and decision making. (3) Post-commit pauses are long intervals after a character is committed and before the next input event, which may signal planning at the lexical, syntactic, or discourse level. For all three pause types, occurrence rates were normalized by the total number of committed characters (i.e., computed per character).

Beyond backspace rate (immediate deletions), we also computed a broader edit rate, defined as the proportion of all input operations that involved revision actions in the middle of the text (e.g., deletions and substitutions). This measure was used to capture monitoring and revision activity during writing.

For time-based measures (e.g., inter-key interval, selection latency, and post-commit gap), we report both the mean and the median to better represent their typically skewed distributions. For inter-key interval, we additionally computed the standard deviation and the coefficient of variation ($CV = \frac{\sigma}{\mu}$) to quantify the stability and relative variability of input rhythm.

3.4 Comparative Analysis

After extracting Pinyin input process features, we compared the two writing tasks on each metric. All analyses were conducted within participants to control for stable individual differences.

For each metric, we first tested the normality of the paired difference scores using the Shapiro-Wilk test. If the normality test was not significant ($p > .05$), we used a paired-samples t test to compare task conditions, otherwise Wilcoxon signed-rank test was applied. We controlled the inflation of Type I error due to multiple comparisons using the Benjamini-Hochberg (BH) procedure. Statistical significance was determined based on BH-adjusted *p* values.

3.5 Correlating Analysis

The writing quality of Task 2 was assessed using Nussbaum's holistic argumentation rubric, with scores ranging from 0 to 7. All essays were scored independently by two trained raters. Inter-rater reliability was evaluated using Kendall's tau (τ) and linearly weighted Cohen's kappa (κ). Agreement was acceptable to high ($\tau = 0.840$, $\kappa = 0.671$), indicating that the scoring procedure was reliable. The holistic argumentation scores derived from Task 2 yielded a mean of 4.51 (SD = 1.31, range = 1.50–6.50). For subsequent analyses, we used the mean of the two raters' scores.

To examine the predictive value of Pinyin input features for writing quality, we related 14 key process metrics extracted from Task 2 to the final argumentation scores. A Shapiro-Wilk test indicated that the score distribution did not significantly deviate from normality ($W = 0.953$, $p = 0.151$), supporting the use of Pearson correlation analysis.

4. RESULTS

4.1 Comparative Analysis of Pinyin Input Behaviors Across Tasks

The study first compared the characteristics of participants' Pinyin input behaviors between the transcription task (Task 1) and the argumentative writing task (Task 2). As shown in Table 2, the shift in task type exerted a significant impact on participants' input rhythm, cognitive processing latency, and input strategies, providing preliminary support for Hypothesis 1 (H1).

Table 2: Task Comparison Results for Pinyin Input Features

Metric	Test Type	p_{adj}	*d*	*r*	z
Full Input Ratio	T-test	0.214	-0.233		
Initial Input Ratio	T-test	0.077	-0.334		
Prefix Input Ratio	Wilcoxon	0.030		0.459	-2.676
Mean IKI	Wilcoxon	<0.001		0.872	-5.086
SD of IKI	Wilcoxon	<0.001		0.872	-5.086
CV of IKI	T-test	<0.001	1.577		
Backspace Rate	Wilcoxon	0.027		0.682	-3.975
Mean Selection Latency	T-test	<0.001	-1.252		
Median Selection Latency	T-test	<0.001	-1.477		
Median Post-commitment Gap	Wilcoxon	<0.001		0.849	-4.949
Global Edit Rate	Wilcoxon	0.030		0.394	-2.299
Within-character Pause Rate	Wilcoxon	0.454		0.216	-1.257
Selection Pause Rate	T-test	<0.001	-0.798		
Post-commit Pause Rate	T-test	0.370	0.165		

At the physical keystroke level, a systemic decline in input fluency was observed when participants transitioned from simple character transcription to complex argumentative writing. Statistical results indicated that the mean Inter-Key Interval (Mean IKI) and its standard deviation (SD of IKI) were significantly higher in Task 2 than in Task 1 ($Z = -5.086$, $p_{adj} < .001$, $r = .872$). More importantly, the Coefficient of Variation of IKI (CV of IKI), which measures the relative stability of input rhythm, increased drastically in the writing task ($p_{adj} < .001$, Cohen's $d = 1.577$).

Changes in cognitive-layer metrics further revealed the cognitive load imposed by the writing task. During the candidate character recognition phase, both the mean and median Selection Latency were significantly longer in the writing task compared to the transcription task ($p_{adj} < .001$). Simultaneously, the Selection Pause Rate increased significantly ($p_{adj} < .001$). Furthermore, the Median Post-commit Gap was significantly extended in Task 2 ($Z = -4.949$, $p_{adj} < .001$, $r = .849$).

Regarding input strategies and monitoring, participants exhibited distinct compensatory and regulatory tendencies. While the ratios of full-pinyin and initial-pinyin strategies showed no significant changes, the Prefix Input Strategy Ratio rose significantly in the writing task ($Z = -2.676$, $p_{adj} = .030$, $r = .459$). Meanwhile, both the Backspace Rate ($p_{adj} = .027$) and the Global Edit Rate ($p_{adj} = .030$) were significantly higher in Task 2 than in Task 1. This indicates that the writing task triggered more frequent evaluation and revision activities\.

4.2 Correlation Between Pinyin Input Features and Argumentative Writing Quality

To address RQ3, we conducted Pearson correlation analyses between the 14 key process features extracted from the creative writing task (Task 2) and the holistic argumentation scores. The results revealed that cognitive-layer pause metrics were the most robust predictors of writing quality, while physical-layer fluency and input strategies showed no significant linear relationship with the final product's quality (see Table 3).

Table 3: Pearson Correlations Between Pinyin Input Features and Argumentation Scores (p < .01)**

Metrics	*r*	*p*	95%CL
Full Input Ratio	-0.127	0.480	[-0.451, 0.226]
Initial Input Ratio	0.249	0.162	[-0.103, 0.546]
Prefix Input Ratio	-0.204	0.255	[-0.511, 0.150]
Mean IKI	-0.123	0.496	[-0.447, 0.230]
SD of IKI	-0.058	0.750	[-0.393, 0.291]
CV of IKI	0.016	0.928	[-0.329, 0.358]
Backspace Rate	0.036	0.844	[-0.311, 0.374]
Mean Selection Latency	-0.036	0.842	[-0.375, 0.311]
Median Selection Latency	-0.114	0.528	[-0.440, 0.239]
Mean Post-commit Gap	0.018	0.922	[-0.328, 0.359]
Global Edit Rate	0.175	0.330	[-0.179, 0.489]
Within-character Pause Rate	-0.482**	0.005	[-0.708, -0.166]
Selection Pause Rate	-0.030	0.870	[-0.369, 0.317]
Post-commit Pause Rate	-0.465**	0.006	[-0.697, -0.145]

Statistical analysis identified two critical cognitive-layer indicators that were significantly and negatively correlated with argumentation scores. Specifically, the Within-character Pause Rate ($r = -.482$, $p = .005$, 95% CI [−.708, −.166]) and the Post-commit Pause Rate ($r = -.465$, $p = .006$, 95% CI [−.697, −.145]) showed moderate negative correlations with writing quality.

Notably, physical-layer metrics such as Mean IKI ($r = -.123$, $p = .496$, 95% CI [-0.447, 0.230]) and Median Selection Latency ($r = -.114$, $p = .528$, 95% CI [-0.440, 0.239]) failed to reach statistical significance. This decoupling indicates that the mere speed of finger movement or character selection does not inherently translate to superior intellectual output in Chinese writing. Furthermore, input strategy ratios, such as the Initial Input Ratio ($r = .249$, $p = .162$, 95% CI [-0.103, 0.546]) and Prefix Input Ratio ($r = -.204$, $p = .255$, 95% CI [-0.511, 0.150]), were also not significantly associated with scores.

Table 4 provides a compact summary of hypothesis testing results. H1a and H1b were fully supported, showing greater timing variability and longer cognitive processing intervals in writing than copying. H1c received partial support. Revision-related behaviors (backspace rate and global edit rate) were significantly higher in the writing task, while only one of the strategic input indicators (prefix-based input ratio) showed a significant increase. Other strategy ratios did not differ reliably across tasks. H2 was supported: only cognitively grounded pause indicators were significantly associated with writing quality, whereas low-level motor timing metrics were not.

Table 4: Compact summary of hypothesis testing results. Detailed statistics are reported in Tables 2–3.

	Indicators	Key evidence	Verdict
H1a	CV of IKI	$p_{adj} < .001$, d = 1.577	Supported
H1b	Selection latency	$p_{adj} < .001$, d = -1.252	Supported
H1b	Post-commit gap	$p_{adj} < .001$, r = 0.849	Supported
H1c	Backspace rate	$p_{adj} = .027$, r = 0.682	Supported
H1c	Global edit rate	$p_{adj} = .030$, r = 0.394	Supported
H1c	Full Input Ratio	$p_{adj} = .214$, d = -0.233	Not Supported
H1c	Initial Input Ratio	$p_{adj} = .077$, d = -0.334	Not Supported
H1c	Prefix Input Ratio	$p_{adj} = .030$, r = 0.459	Supported
H2	Within-character pause rate vs. Score	r = −.48, p < .01	Supported
H2	Post-commit pause rate vs. Score	r = −.47, p < .01	Supported

5. DISCUSSION

The present study investigated the characteristics of Chinese Pinyin input behaviors and their relationship with writing quality through the lens of a Dual-layer Rhythm Model. Utilizing fine grained keystroke logging and feature engineering techniques, we captured the nuanced shifts in input patterns as participants transitioned from transcription to argumentative writing. The results confirmed that task induced cognitive load significantly alters physical rhythm, cognitive latency, and input strategies. Most crucially, the correlation analysis revealed that cognitive layer pauses metrics, specifically the Within-character Pause Rate and the Post commit Pause Rate, serve as robust predictors of argumentation quality, whereas physical fluency metrics such as Mean Inter Key Interval do not.

A central finding of this study is the significant negative correlation between the Within-character Pause Rate, the Post-commit Pause Rate, and holistic writing scores. From the perspective of feature engineering, these two metrics constitute diagnostic markers for identifying cognitive bottlenecks during the writing process.

The Within-character Pause Rate reflects difficulties during the phonological encoding phase. In Pinyin-mediated writing, the writer must transform abstract mental concepts into specific phonetic sequences. High quality writers exhibit a high degree of automaticity in this phase. Conversely, frequent prolonged pauses during Pinyin spelling among lower scoring writers suggest that lower-level phonology to orthography conversion consumes excessive cognitive resources. Crucially, this relationship may be bidirectional: the intensive cognitive load inherent in high-level argumentative planning can interfere with the execution of motor

sequences, causing even potentially automated Pinyin input to stutter. According to Working Memory Theory, such non automated lower-level processing creates cognitive competition, thereby depleting the mental resources available for high level argumentative planning and reasoning.

The Post-commit Pause Rate marks the transition from text generation to higher-level macro-planning. Higher-quality writers typically demonstrate stronger pre-planning capacity or more fluent syntactic production, resulting in fewer disruptions between linguistic units. This finding suggests that typing speed alone is not a reliable indicator of writing quality. Consistent with writing-process and keystroke-logging research, cognitively grounded timing features—such as pause distribution—provide more informative signals of composing quality than raw physical execution speed, especially in Pinyin-mediated Chinese writing.

The observed decoupling between physical layer metrics such as Mean Inter Key Interval and writing scores provides significant insights for educational data mining. This phenomenon suggests that in a population of graduate students, physical execution of Pinyin input has reached a stage of high automaticity, essentially becoming background noise in the writing process.

The true variance in writing expertise is concealed within the decision latencies and pause patterns that occur after the physical keystroke sequences. This validates the necessity of our proposed DLRM. Only by isolating the interference of physical execution can researchers accurately capture the cognitive features truly associated with the quality of thought and argumentation.

From the standpoint of Educational Data Mining, the identification of these two critical pause features provides an empirical foundation for developing process oriented intelligent writing systems. Future automated writing evaluation tools could move beyond product-based scoring to provide real time diagnostics. By monitoring the Within-character Pause Rate and the Post commit Pause Rate, a system could distinguish whether a writer is struggling with spelling retrieval or conceptual planning and offer personalized scaffolding accordingly.

Despite these insights, several limitations should be noted. First, the sample size of 34 and the focus on graduate students limit the generalizability of the findings to younger or less proficient populations. Future research should include diverse groups, such as elementary students or second language learners, to test the model's robustness.

Second, this study primarily focused on the incremental generation phase. Macro level editing behaviors, such as structural reorganization or cross paragraph revisions, were not explored in depth. Future studies could integrate eye tracking technology with sequential pattern mining to investigate the recursive nature of the writing process, thereby constructing a more comprehensive feature library for Chinese digital writing.

6. CONCLUSION

This study proposed and validated a Dual-layer Rhythm Model to analyze the cognitive mechanisms underlying Chinese Pinyin input during writing tasks. By leveraging fine grained keystroke logging and data mining techniques, we successfully decoupled the physical execution layer from the cognitive processing layer in digital writing. The results demonstrate that while high level writing tasks induce a systemic decline in physical typing fluency, it is the cognitive layer pauses, specifically those occurring within Pinyin character construction and after character commitment, that serve as significant indicators of writing quality.

The theoretical contribution of this research lies in identifying the unique phonological to orthographical translation costs inherent in Pinyin input, which have been largely overlooked in traditional alphabetic keystroke research. Practically, the identified diagnostic features provide a foundation for developing next generation intelligent writing environments. These systems can transition from static text evaluation to dynamic process monitoring, offering timely interventions when cognitive bottlenecks are detected. Future work will focus on integrating these process features into machine learning models to enhance the predictive accuracy of automated writing assessment systems across diverse learner populations.

7. APPENDIX

7.1 Appendix A. Transcription Text

假如说逻辑一般被认为是思维的科学，那么，人们对于它的了解是这样的，即：好像这种思维只构成知识的单纯形式；好像逻辑抽去了一切内容，而属于知识的所谓第二组成部分，即质料，必定另有来源；好像完全不为这种质料所依赖的逻辑，因而只能提供真正知识的形式条件，而不能包含实在的真实本身，也不能是达到实在的真理的途径，因为真理的本质的东西，内容，恰恰在逻辑以外。

7.2 Appendix B. Argument Prompt

The following is a memorandum from the business manager of a television station. "Over the past year, our late-night news program has devoted increased time to national news and less time to weather and local news. During this period, most of the complaints received from viewers were concerned with our station's coverage of weather and local news. In addition, local businesses that used to advertise during our late-night news program have canceled their advertising contracts with us. Therefore, in order to attract more viewers to our news programs and to avoid losing any further advertising revenues, we should expand our coverage of weather and local news on all our news programs."

Write a response in which you examine the stated and/or unstated assumptions of the argument. Be sure to explain how the argument depends on these assumptions and what the implications are for the argument if the assumptions prove unwarranted.

8. ETHICS AND CONSENT TO PARTICIPATE

Formal ethical approval was not required for this study in accordance with national and institutional guidelines, as determined by the Institutional Review Board of the University of Science and Technology of China. The study involved anonymous data collection and posed no foreseeable risk to adult participants. Participation was voluntary, and informed consent was obtained from all participants prior to data collection. If required, documentation confirming the exemption from IRB review can be provided.

9. ACKNOWLEDGMENTS

This research was also supported by the advanced computing resources provided by the Supercomputing Center of the USTC.

ABSTRACT

Student dropout is a major challenge in large-scale supplementary education, where early identification of at-risk learners is essential. Although prior educational data mining studies have explored dropout prediction using learning logs, long-term test-based data common in offline settings remain underexplored. This industry paper reports a real-world application of dropout prediction using longitudinal standardized test data from over 3,000 junior high school students in a large Japanese cram school. We engineered interpretable features capturing achievement dynamics, including recovery efficiency after score declines and trend consistency. Random Forest models trained on a previous cohort were validated on an independent cohort. The best-performing model achieved approximately 89% accuracy and a dropout F1-score of 0.80, enabling prediction before the final academic year. Feature importance analysis showed that recovery from performance declines was a stronger indicator of dropout risk than absolute achievement. These results demonstrate that longitudinal test data can support accurate and interpretable dropout prediction at scale, offering practical value for early intervention.

Keywords

Dropout prediction, Early warning, Longitudinal assessment, Cram school

1. INTRODUCTION

Student dropout is a persistent challenge in large-scale supplementary education, where learners and families invest substantial time and financial resources over multiple years. For providers, dropout not only disrupts learning continuity but also limits the effectiveness of long-term curricular planning and student support. Accordingly, there is growing interest in early-warning systems that can identify at-risk learners early enough to enable timely, targeted interventions rather than reactive responses after disengagement becomes irreversible [1][3]. In this study, a cram school refers to a private supplementary education institution that provides after-school academic instruction, primarily aimed at supporting students' preparation for high school entrance examinations.

Educational Data Mining (EDM) and Learning Analytics (LA) research has produced a broad body of work on dropout prediction using machine learning, often leveraging digital trace data such as LMS activity logs, clickstream behavior, and online engagement metrics (e.g., [1][8]).

In many offline or hybrid educational settings, however, these fine-grained behavioral logs are limited or unavailable. Instead, institutions frequently maintain longitudinal assessment records—standardized tests or periodic mock exams—collected consistently over multiple years. While dropout prediction has also been studied with administrative and academic records (e.g., transcripts, credits, grades), evidence remains comparatively thinner regarding how to transform repeated test performance trajectories into actionable early warning signals in real-world, offline-dominant contexts[8].

While various ensemble learning techniques, such as Random Forests [2] and Gradient Boosting Decision Trees like XGBoost [4] and GBM [6], have demonstrated high predictive accuracy in these domains, their application to offline longitudinal records requires careful adaptation. Specifically, beyond achieving high accuracy, it is critical to ensure model interpretability—a growing focus in recent EDM research [7]—so that predictions can directly inform pedagogical interventions. In this study, we employ a Random Forest approach [2] not only for its robust performance but also to validate the effectiveness of our interpretable feature engineering framework.

This gap is particularly relevant for supplementary education providers (e.g., cram schools), where periodic test-based evaluation is central to instructional decision-making. Prior EDM work has shown the potential of predictive modeling in Japanese cram school contexts—for example, using teacher observation reports and exam scores for performance prediction[5]. Building on this line of industry-relevant EDM, we focus specifically on dropout prediction using data that many supplementary education providers already possess at scale: multi-year standardized test records.

In this industry paper, we investigate how longitudinal standardized test data can be utilized to support early identification of students at risk of dropout in large-scale supplementary education. We focus on a real-world setting in which repeated test-based assessments are routinely collected but fine-grained digital learning logs are limited or unavailable. To address this context, we design a feature engineering framework that captures students' achievement dynamics over time, including responses to performance declines, stability of learning trajectories, and distributional patterns of subject performance. We then examine how such interpretable temporal indicators can be integrated into machine learning models for practical early-warning applications. Through cohort-based model development and independent cohort validation, this study aims to evaluate the feasibility, generalizability, and operational relevance of dropout prediction using offline longitudinal assessment records. Ultimately, we seek to clarify whether existing assessment infrastructures in supplementary education can be adapted into data-driven early-warning systems that support timely and targeted student interventions.

2. METHODS

2.1 Context, Data, and Outcome Definition

This study was conducted in collaboration with a large-scale Japanese cram school that prepares students for high school entrance examinations. We analyzed longitudinal standardized test records collected routinely as part of instructional practice.

To ensure consistent longitudinal trajectories, we restricted the cohort to students who participated in the first Grade 7 diagnostic test (N = 3,316). Students subsequently took up to 15 standardized diagnostic and mock examinations from Grade 7 to Grade 9. Participation decreased over time, with 2,200 students remaining at the final Grade 9 test, corresponding to a 33.6% reduction from the initial cohort. An overview of the dataset, observation period, and evaluation design is summarized in Table 1.

Table 1. Overview of the Dataset

Item	Description
Educational setting	Large-scale Japanese cram school preparing students for high school entrance examinations
Initial cohort	3,316 students who participated in the first Grade 7 diagnostic test
Observation period	Grade 7 (Year 1) to Grade 9 (Year 3)
Number of test occasions	Up to 15 standardized diagnostic and mock examinations
Subjects analyzed	Native language, Mathematics, English, overall average
Label definition	Graduates: students with a graduation flag; Dropouts: test participants without the flag
Final test participants	2,200 students at the final Grade 9 test (33.6% decrease from initial cohort)
Minimum tests required	3 test participations (for feature computation)
Evaluation sample size	~3,100 students (varies by model due to minimum test requirement)
Validation design	Train on 2024 cohort, validate on independent 2025 cohort

Students were labeled as *graduates* if they were flagged as having completed enrollment through the final examination. Test participants without this flag were labeled as *dropouts*. In addition, for each test occasion, we recorded whether that test became the student's final attempt, enabling analysis of withdrawal timing. We utilized anonymized data provided by the cram school. The use of this data underwent internal review and approval by the partnering cram school and the institution and was handled in strict compliance with relevant privacy guidelines.

2.2 Assessment Timeline and Subjects

The assessment sequence consisted of four Grade 7 diagnostic tests, transitional mock examinations at grade boundaries (e.g., "new Grade 8" and "new Grade 9"), and multiple Grade 8–9 high school entrance mock tests. Each test included subject-level scores and standardized deviation scores for Native language, Mathematics, and English, as well as overall averages.

This repeated assessment structure enabled us to model not only performance levels but also longitudinal achievement dynamics across critical transitional periods in lower secondary education.

2.3 Feature Engineering

Rather than relying solely on raw test scores, we engineered interpretable features designed to capture students' longitudinal achievement dynamics. Feature design was conducted in close consultation with practitioners to ensure pedagogical relevance and operational usability in real educational settings.

In total, 98 features were engineered from subject-wise scores and standardized deviation scores across test occasions. These features fall into several conceptual categories, summarized with representative examples in Table 2.

Key feature categories include:

1). Recovery-related indicators, measuring how efficiently a student's performance rebounds after a decline (e.g., score recovery efficiency).
2). Trend-based indicators, capturing the direction, slope, and instability of longitudinal change (e.g., linear regression slopes and directional change ratios).
3). Consistency indicators, representing the proportion of changes occurring in the same direction over time.
4). Distributional indicators, such as proportions of high scores (>80), passing scores (>60), and low scores (<40).
5). Relative strength indicators, quantifying subject-wise performance relative to a student's overall average.

For example, recovery efficiency quantifies how effectively a student returns to their individual mean performance following a score decrease, while directional change ratio reflects instability in achievement trajectories caused by frequent switches between improvement and decline.

Table 2. Categories of Engineered Features and Representative Examples

Category	Description	Representative examples
Recovery-related	Ability to rebound after performance decline	Score recovery efficiency (Native language, Mathematics)
Trend-based	Direction and stability of longitudinal change	Linear slope, directional change ratio

Category	Description	Representative examples
Consistency	Stability of improvement or decline	Trend consistency ratio
Distributional	Performance level distribution	High-score ratio (>80), low-score ratio (<40)
Relative strength	Subject-wise relative performance	Subject mean / overall mean

2.4 Modeling Approach

We formulated dropout prediction as a supervised binary classification task. Specifically, we employed the Random Forest algorithm [2], which is widely used in educational data mining for its robustness to overfitting and interpretability. The Random Forest model was implemented using standard hyperparameter settings, including 100 decision trees (n_estimators = 100). Hyperparameters were selected through grid search on the training cohort to optimize predictive performance while avoiding overfitting. To examine the trade-off between prediction timing and performance, we constructed three models that differed in the length of available longitudinal data:

Model 1: Grade 7 Test 1 to Grade 9 Test 6

Model 2: Grade 7 Test 1 to Grade 9 Test 4

Model 3: Grade 7 Test 1 to Grade 9 Test 3

These models correspond to different potential intervention points, with earlier models providing more time for support but less complete information.

Models were trained using the 2024 graduating cohort and evaluated using accuracy and F1-scores for both graduates and dropouts. Because dropout detection is of primary operational importance and the classes are imbalanced, particular emphasis was placed on the dropout F1-score when comparing models.

2.5 Validation Procedure and Evaluation Metrics

To assess generalizability, all models were validated on an independent 2025 graduating cohort. Because feature computation required a minimum of three test participations, the evaluation sample size varied slightly across models, as summarized in Table 1.

Performance was evaluated using accuracy, precision, recall, and F1-scores for both classes. For the selected model, we additionally report a confusion matrix to clarify precision–recall trade-offs relevant to operational deployment.

2.6 Model Selection Criterion

Model selection was based on three criteria:

1). predictive performance, particularly dropout F1-score;

2) prediction timing, enabling intervention before the final academic year; and

3) operational interpretability for practitioners.

Based on these criteria, Model 2 was selected as the most suitable for real-world deployment, achieving strong predictive performance while enabling sufficiently early identification of at-risk students.

3. RESULTS

3.1 Model Comparison and External Validation

Table 3 summarizes the performance of the three dropout prediction models evaluated on the independent 2025 cohort. All models achieved high overall accuracy, ranging from 88.2% to 89.5%, demonstrating that longitudinal test performance data can support reliable dropout prediction at scale.

Table 3. Performance Comparison of Dropout Prediction Models

Model	Data used	Accuracy	Graduate F1	Dropout F1
Model 1	Grade 7 Test 1 – Grade 9 Test 6	88.2%	0.91	0.81
Model 2	Grade 7 Test 1 – Grade 9 Test 4	89.5%	0.93	0.80
Model 3	Grade 7 Test 1 – Grade 9 Test 3	89.1%	0.93	0.78

Among the three models, Model 2, which used test data from Grade 7 Test 1 to Grade 9 Test 4, achieved the best balance between predictive performance and early identification. Specifically, Model 2 attained an accuracy of 89.5%, a graduate F1-score of 0.93, and a dropout F1-score of 0.80. While Model 1 achieved comparable performance, it relied on a longer observation period extending to the final Grade 9 test, limiting its usefulness for early intervention. In contrast, Model 3 enabled earlier prediction but exhibited a lower dropout F1-score, indicating reduced sensitivity for identifying at-risk students.

Figure 1 visualizes this trade-off between prediction timing and predictive performance across the three models. The results indicate that incorporating test data up to Grade 9 Test 4 is sufficient to achieve strong performance while still allowing institutions to intervene before the final academic year.

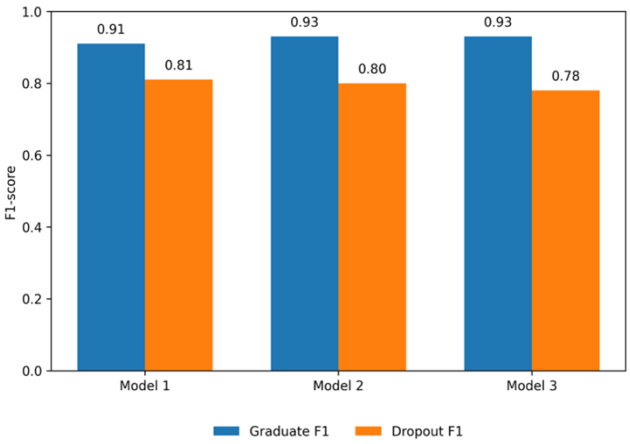

Figure 1. Model Comparison

3.2 Operational Performance of the Selected Model

To examine the practical implications of deployment, we further analyzed the operational performance of Model 2, focusing on precision–recall trade-offs relevant to real-world intervention. As shown in Table 3, Model 2 achieved a dropout precision of approximately 81% and a dropout recall of approximately 80%, indicating that the majority of students identified as high risk indeed withdrew, while a substantial proportion of actual dropouts were successfully detected.

From an operational perspective, this balance suggests that the model can be used to prioritize support resources toward students most likely to disengage, without overwhelming instructors with excessive false positives. Importantly, the model maintained high graduate recall, ensuring that students likely to remain enrolled were not systematically misclassified.

3.3 Feature Importance and Interpretability

To better understand why the models achieved strong predictive performance, we examined feature importance and group-level differences between graduates and dropouts. Across all models, recovery-related indicators consistently ranked among the most influential predictors.

In particular, score recovery efficiency in Native language and Mathematics emerged as the top-ranked features in Model 2. Graduates showed substantially higher recovery efficiency than dropouts, indicating that their performance was more likely to rebound after temporary declines. For example, the mean recovery efficiency in Native language was 0.84 for graduates compared to 0.60 for dropouts, with a similar pattern observed in Mathematics. Differences across the top-ranked features were statistically significant ($p < .01$, independent samples t-test). Assumptions of normality were considered acceptable given the large sample size.

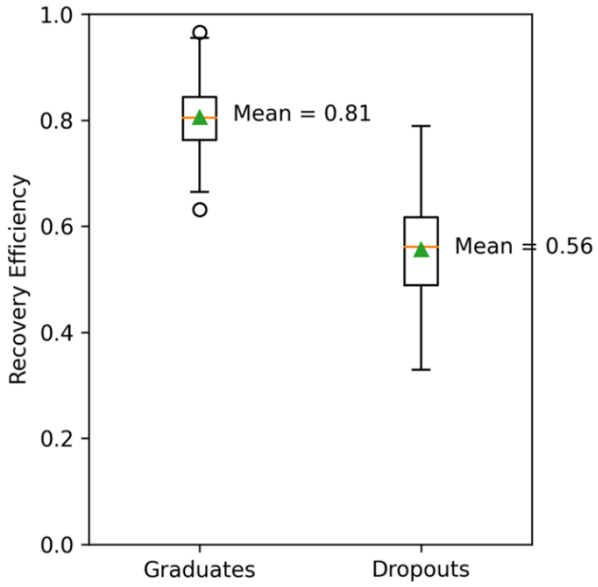

Figure 2. Mathematics test score recovery efficiency

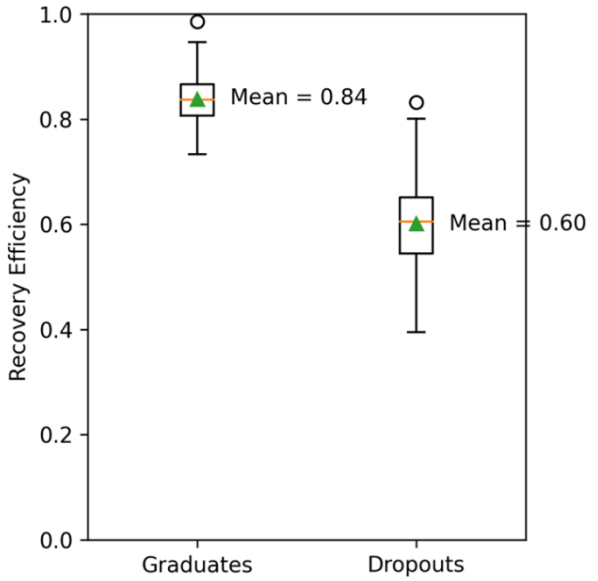

Figure 3. Native language test score recovery efficiency

Figures 2, 3, and 4 presents the distributions of score recovery efficiency for graduates and dropouts across three core subjects. In Mathematics (Figure 2), graduates showed higher recovery efficiency (Mean = 0.81) compared with dropouts (Mean = 0.56). Similarly, In Native language (Figure 3), graduates exhibited substantially higher recovery efficiency (Mean = 0.84) than dropouts (Mean = 0.60). The same pattern was observed in English(Figure 4), where graduates again demonstrated higher recovery efficiency than dropouts. These group differences indicate that the ability to recover after declines is strongly associated with continued enrollment.

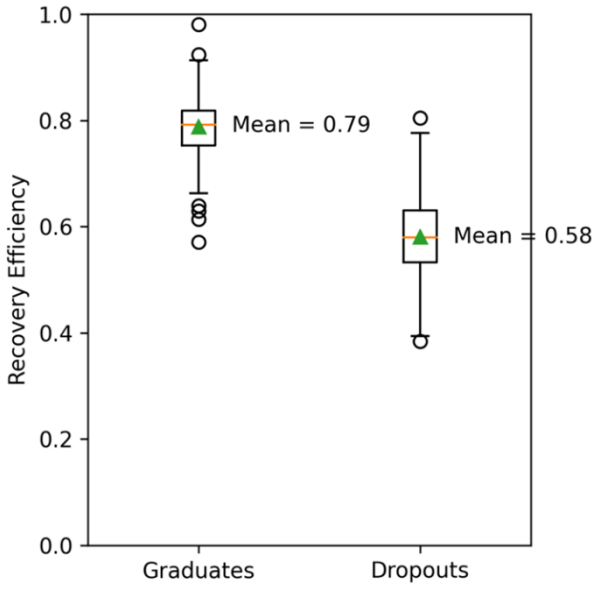

Figure 4. English test score recovery efficiency

3.4 Beyond Absolute Performance Levels

Notably, absolute achievement levels alone were less predictive than longitudinal performance dynamics. Several trend-based features, such as continuous negative deviation slopes and high directional change ratios, were also associated with increased dropout risk. These findings suggest that instability and sustained decline, rather than low scores per se, play a critical role in student disengagement. This emphasis on achievement dynamics aligns with practitioners' observations that students who struggle to recover from setbacks are more likely to lose motivation and eventually withdraw, even if their overall performance remains near average.

3.5 Summary of Key Findings

In summary, the results show that:

(1) dropout prediction using longitudinal test data generalizes well across cohorts (Table 3, Figure 1)

(2) Model 2 provides an effective balance between early prediction and dropout detection performance (Table 3, Figure 1)

(3) interpretable indicators capturing recovery from performance declines consistently differentiate graduates from dropouts across Native language, Mathematics, and English (Figures 2, 3, and 4). Together, these findings support the practical applicability of the proposed approach for early identification and intervention in large-scale supplementary education settings.

4. DISCUSSION

4.1 Practical Implications for Supplementary Education Providers

This study demonstrates that longitudinal standardized test data, which are routinely collected in large-scale supplementary education settings, can be leveraged to build accurate and interpretable dropout prediction models. Unlike prior educational data mining studies that primarily rely on digital learning logs, our approach utilizes offline test records, making it directly applicable to institutions where learning activity logs are limited or unavailable.

The selected model (Model 2) achieved strong predictive performance while enabling identification of at-risk students before the final academic year (Table 3, Figure 1). From an operational perspective, this timing is critical: interventions initiated after Grade 9 Test 4 still allow sufficient time for academic counseling, motivational support, or tailored instructional planning. The achieved balance between dropout precision and recall indicates that the model can guide resource allocation without overwhelming instructors with excessive false positives.

These results suggest that supplementary education providers can integrate predictive analytics into existing assessment infrastructures with minimal additional data collection burden. In practice, this supports data-driven early-warning systems that prioritize students requiring attention, thereby improving retention and educational outcomes.

4.2 Interpretability and Educational Meaning of Recovery Efficiency

Beyond predictive performance, an important contribution of this study lies in the interpretability of the proposed features. Across all subjects, recovery efficiency consistently distinguished graduates from dropouts (Figures 2–4), indicating that resilience to academic setbacks is a central factor associated with continued enrollment. Notably, absolute achievement levels alone were less informative than performance dynamics, aligning with practitioners' observations that disengagement often follows repeated failures to rebound from declines rather than single low test scores.

This finding offers actionable insights for educators. Students with persistently low recovery efficiency may benefit from targeted interventions focusing on study strategies, self-regulation, or motivational support. Thus, the model does not merely predict dropout risk but also provides interpretable indicators that inform the design of individualized support measures.

4.3 Contribution to Industry-Oriented Educational Data Mining

From an industry-oriented EDM perspective, this work contributes a real-world case study demonstrating how predictive modeling can be embedded into commercial educational operations at scale. The dataset spans over 3,000 students across three academic years, and the models were validated on an independent graduating cohort, addressing a common limitation of prior studies that rely on single-cohort evaluation.

Furthermore, the feature engineering strategy—summarized in Table 2—offers a reusable framework for institutions seeking to derive meaningful predictors from longitudinal assessment data. The emphasis on recovery-related and trend-based features highlights the value of modeling temporal learning trajectories, extending beyond traditional snapshot-based performance indicators.

5. LIMITATIONS AND FUTURE WORK

Several limitations should be acknowledged. First, the present analysis focuses primarily on longitudinal test performance data and does not incorporate behavioral or attitudinal measures such as attendance records, homework completion, or survey-based motivation indicators. Integrating multimodal data sources, including digital learning logs and other behavioral traces, may further enhance predictive performance and provide richer explanatory insights into student disengagement processes. In addition, the dataset includes students whose final outcomes were not fully

observed at the time of analysis. These cases may be considered as right-censored data, which could introduce uncertainty in the definition of dropout status.

Second, while the current models generalize across cohorts within a single institution, external validation across different supplementary education providers remains an important direction for future research. Institutional differences in curricula, testing schedules, or instructional policies may influence feature distributions and model transferability. In addition, ensuring the reproducibility of the proposed feature engineering procedures and modeling pipeline across diverse institutional contexts will be essential for broader deployment and comparative evaluation[9].

Finally, the present study examines prediction at discrete test intervals. Future work may explore continuous risk monitoring frameworks that update predictions as new assessments become available, enabling more adaptive intervention strategies [10]. Such extensions could also incorporate fine-grained learning logs [11][12], where available, to complement test-based indicators and support more responsive early-warning systems.

6. CONCLUSION

This industry paper presented a real-world application of dropout prediction in large-scale supplementary education using longitudinal standardized test data. By engineering interpretable features capturing achievement dynamics and validating models on an independent cohort, we demonstrated that early identification of at-risk students can be supported using routinely collected assessment records. The selected model achieved stable predictive performance while enabling intervention before the final academic year.

Beyond predictive accuracy, the analysis indicated that recovery efficiency after performance declines is consistently associated with student persistence across Native language, Mathematics, and English. This insight offers practical guidance for designing targeted academic support.

While several limitations remain and further validation across institutions and data modalities is needed, the proposed approach illustrates how existing assessment infrastructures can be adapted into practical early-warning systems, contributing operational value for educational service providers and methodological insights for industry-oriented educational data mining.
